KEY TO PRONUNCIATION

For a full explanation of the various sounds indicated, see the KEY TO PRONUNCIATION in Vol. I.

ā	as in ale, fate.	ch	as in chair, cheese.
ā	" " senate, chaotic.	d	" " Spanish Almodovar, pulgada, where it is nearly like <i>th</i> in English then.
ā	" " glare, care, and as <i>e</i> in there.	g	" " go, get.
ā	" " am, at.	g	" " German Landtag = <i>ch</i> in Ger. ach, etc.
ā	" " arm, father.	h	" <i>j</i> in Spanish Jijona, <i>g</i> in Spanish gila; like English <i>h</i> in hue, but stronger.
ā	" " ant, and final <i>a</i> in America, armada, etc.	hw	" <i>wh</i> in which.
ā	" " final, regal, pleasant.	k	" <i>ch</i> in German ich, Albrecht = <i>g</i> in German Arensberg, Mecklenburg, etc.
ā	" " all, fall.	u	" in sinker, longer.
ā	" " eve.	ng	" " sing, long.
ā	" " elate, evade.	n	" " French bon, Bourbon, and <i>m</i> in the French Étampes; here it indicates nasalizing of the preceding vowel.
ā	" " end, pet.	sh	" " shine, shut.
ā	" " fern, her, and as <i>i</i> in sir, etc.	th	" " thrust, thin.
ā	" " agency, judgment.	th	" " then, this.
ā	" " ice, quiet.	zh	" <i>z</i> in azure, and <i>s</i> in pleasure.
ā	" " quiescent.		
ā	" " ill, fit.		
ā	" " old, sober.		
ā	" " obey, sobriety.		
ā	" " orb, nor.		
ā	" " odd, forest, not.		
ā	" " atom, carol.		
oi	" " oil, boil.		
ō	" " food, fool, and as <i>u</i> in rude, rule.		
ou	" " house, mouse.		
ū	" " use, mule.		
ū	" " unite.		
ū	" " cut, but.		
ū	" " full, put, or as <i>oo</i> in foot, book.		
ū	" " urn, burn.		
y	" " yet, yield.		
z	" " Spanish Habana, Córdoba, where it is like English <i>v</i> but made with the lips alone.		

An apostrophe ['] is sometimes used as in tā'b'l (table), kāz'm (chasm), to indicate the elision of a vowel or its reduction to a mere murmur.

For foreign sounds, the nearest English equivalent is generally used. In any case where a special symbol, as *g*, *h*, *k*, *x*, is used, those unfamiliar with the foreign sound indicated may substitute the English sound ordinarily indicated by the letter. For a full description of all such sounds, see the article on PRONUNCIATION.

A PARTIAL LIST OF THE LEADING ARTICLES IN VOLUME VII

- DIES AND DIE-SINKING.
Mr. Moses Nelson Baker.
Dr. Frederick Remsen Hutton.
- DIET.
Dr. David G. Yates.
- DIFFRACTION AND DIFFRACTION GRATINGS.
Professor Joseph Sweetman Ames.
- DIFFUSION.
Professor Martin A. Rosanoff.
- DIGESTION, ORGANS AND PROCESS OF, IN MAN.
Dr. David G. Yates.
- DINOSAURIA.
Mr. Gilbert Van Ingen; Dr. Robert Broom; Mr. C. William Beebe.

ENOCH, BOOKS OF.
Professor Nathaniel Schmidt.

THE NEW INTERNATIONAL ENCYCLOPÆDIA

DIDYMUS (Lat., from Gk. *δίδυμος*, twofold, twain). The Greek translation of the Aramaic *tō'mā'* (Heb. *t'ōm*), a twin, of which *Θῶμας*, *Thōmas*, is the transliteration. It is the alternative name given in the Fourth Gospel (xi. 16; xx. 24; xxi. 2) to one of the disciples of Jesus. Eusebius (*Hist. Eccl.*, i. 13) states that his primary name was Judas, in which case his alternative name would be given him to distinguish him from Judas, the son of James, and from Judas Iscariot (cf. Luke vi. 16). It is of interest to note that the Sinaitic-Syriac manuscript in John xiv. 22 reads "Thomas [instead of Judas], not Iscariot."

DIDYMUS (Lat., from Gk. *Δίδυμος*) (63 B.C. -?). An Alexandrian grammarian of the time of Augustus, famous as author of an enormous number of books, in which he incorporated the works of his predecessors. The total number of his works is given as 3500 by Athenæus and Suidas, by Seneca as 4000. These include commentaries on Homer, Hesiod, Pindar, Bacchylides, Æschylus, Sophocles, Euripides, Eupolis, Cratinus, Aristophanes, Menander, Antiphon, Iseus, Æschines, Demosthenes, Hyperides, and many others. The extant scholia to Homer, Pindar, Sophocles, Euripides, and Aristophanes, in great measure, go back to his commentaries. He published also lexicographical collections on the poets, historians, and orators; wrote on all kinds of questions concerning literary history and composition; and composed historical and antiquarian treatises. From his endless industry he was nicknamed Chalcenteros (*Χαλκέντερος*), 'Brazen-Bowelled.' Among the Romans he was in such high repute that Macrobius called him the most learned grammarian of his own or other times. Consult: Schmidt, *Didymi Chalcenteri Fragmenta* (Leipzig, 1854); Ludwich, *Aristarch's Homerische Textkritik nach den Fragmenten des Didymus* (ib., 1884-85); Wilamowitz, *Herakles*, vol. i (Berlin, 1889); Susemihl, *Geschichte der griechischen Litteratur in der Alexandrinerzeit*, vol. ii (Leipzig, 1892); Sandys, *A History of Classical Scholarship*, vol. i (2d ed., Cambridge, 1906).

DIDYMUS OF ALEXANDRIA (309-394). An ecclesiastical writer. Although he became blind at the age of four, before he had learned to read, he succeeded in mastering all the sciences then known, and on his ordination was placed by Athanasius at the head of the

Alexandrian school of theology. He was a man of great earnestness and piety. Most of his works are lost, but we possess a translation by Jerome (one of his pupils) of his treatise on the Holy Ghost, and a translation by Epiphanius of his comments on the canonical Epistles. A treatise on the Trinity and one against the Manichæans are also extant in Greek. He was condemned by the sixth (680) and seventh (787) ecumenical councils as an Origenist. His works are in Migne, *Patrologia Græca*, xxxix.

DIE. See DICE; DIES AND DIE SINKING.

DIEBITSCH, dē'bich, HANS KARL FRIEDRICH ANTON, COUNT (1785-1831). A Russian field marshal. He was born at Grossleippe, Silesia, and at an early age entered the Russian army. After serving with distinction at Austerlitz, Eylau, and Friedland, and attaining the grade of captain, he devoted a number of years to the study of military science. In 1812 he distinguished himself greatly by recapturing Polotsk and covering the retreat of Wittgenstein's corps. He was then raised to the rank of major general, and shortly afterward, in 1813, after negotiating the Convention of Tauroggen, he was sent into Silesia to serve with General Yorck in the War of Liberation, during which time he shared in the negotiations of Reichenbach. After the battle of Leipzig he was made lieutenant general. In 1814 he urged the march of the Allies on Paris, for which the Emperor conferred on him the order of St. Alexander Nevski. In 1815 he attended the Congress of Vienna and was made adjutant general to the Emperor. He was present at Alexander's death at Taganrog. The Emperor Nicholas made him Baron and afterward Count. In the Turkish War of 1828-29 he had the chief command, took Varna, crossed the Balkans, and made peace at Adrianople. The crossing of the Balkan Mountains was commemorated in the addition of Zabalkanski, 'Crosser of the Balkans' (Russ. *za*, beyond + *Balkany*, the Balkans), to his name and his elevation to the rank of field marshal. On the outbreak of the Polish Revolution in 1830 he was given the chief command, but did not meet with his usual success. He died near Polotsk, June 10, 1831, probably of cholera. Consult Belmont, *Graf Diebitsch* (Dresden, 1830), and Chesney, *Russo-Turkish Campaigns 1828-29* (New York, 1856).

DIEDENHOFEN, dē'den-hō'fen (Fr. *Thion-*

ville). A town of Alsace-Lorraine, in the District of Lorraine, Germany, on the Moselle, 22 miles north of Metz (Map: Germany, B 4). Its old fortifications, of little value on account of the eminences commanding them, were razed in 1903 and the ground laid out in streets. It is the centre of the iron industry of Lorraine, and there is a considerable trade in fruit, vegetables, grain, wine, and wood. Pop., 1900, 10,060; 1910, 14,184. Diedenhofen, known by the name of Theodonisvilla, in the eighth century, was frequently the residence of the Carolingian rulers. It came into the possession of France in 1683 and of Germany in 1871.

DIEFENBACH, dē'fen-bäg, LORENZ (1806-83). A German philologist. He was born at Ostheim, Grand Duchy of Hesse, studied theology and philosophy at Giessen, traveled much, and for 12 years was pastor and librarian at Solms-Laubach. He was one of the founders of the German-Catholic party and in 1848 was a deputy from Offenbach to the Parliament of Frankfurt-on-the-Main. He remained in that city and in 1865 was appointed second municipal librarian. His literary industry was enormous, and his writings include poetry and romance as well as learned philosophical treatises. His principal works are: *Celtica* (3 vols., 1839-40); *Vergleichendes Wörterbuch der gotischen Sprache* (2 vols., 1846-51); *Glossarium Latino-Germanicum Medice et Infimæ Etatis*, a supplement to Ducange's well-known Glossary (1857); *Origines Europææ* (1861); *Hoch- und niederdeutsches Wörterbuch*, with E. Wülcker (2 vols., 1874-85).

DIEFFENBACH, GEORG CHRISTIAN (1822-1901). A German theologian and poet, born at Schlitz, Hesse. He studied at Giessen and in 1871 became chief pastor in Schlitz. His liturgical, poetical, devotional, and homiletic publications are numerous and highly popular, more especially his poems for children.

DIEFFENBACH, JOHANN FRIEDRICH (1795-1847). A German surgeon, born in Königsberg, Prussia. After studying at Bonn and elsewhere, and traveling in France, he took his degree in 1822 and commenced practice in Berlin, where he soon attained distinction as an operator, and in 1840 was promoted to be professor and director of clinical surgery. Besides his operating skill in all the usual operations with the knife, Dieffenbach introduced many improvements, particularly in the art of forming new noses, lips, eyelids, and in other plastic operations. He was the author of *Die transfusion des Blutes und die Einspritzung der Arzneien in die Adern* (1828); *Chirurgische Erfahrungen* (4 vols., 1829-35); *Ueber die Durchschneidung der Sehnen und Muskeln* (1841); *Die Heilung des Stotterns* (1841); *Ueber das Schielen* (1842); *Die operative Chirurgie* (12 vols., 1844-48).

DIEGUEÑOS. A group of Mission Indians (q.v.) living on small reservations near San Diego, Cal. See YUMAN STOCK.

DIELECTRIC AND DIELECTRIC CONSTANT. See ELECTRICITY.

DIELMAN, dē'män, FREDERICK (1847-). An American painter, designer, illustrator, and educator. He was born in Hanover, Germany. He was brought to the United States in infancy, passed his youth in western Maryland, and was educated at Calvert College, Baltimore. From 1866 to 1872 he was a topographer and draftsman in the United States Engineering Department. He then studied

painting with Wilhelm Diez at the Royal Academy of Munich and established a studio in New York in 1876. He soon became known for his charming and minutely executed genre pictures, such as the "Patrician Lady" (T. P. Williams, New York); "My Own Puss" (B. Clarke, New York); "Young Gambler" (B. Clarke, New York); "Young Man against leafy branch" (B. Clarke, New York); and in designing illustrations for collective editions of standard authors and of late years executed designs for mosaic and mural paintings, such as the mosaic panel "Thrift," in the Albany Savings Bank, those of "History" and "Law" in the Congressional Library, Washington, and six mosaics in the Iowa State Capitol, Des Moines. At the St. Louis Exposition he exhibited a series of designs for mural paintings and two aquarelles. He was one of the founders of the Society of American Artists, was elected in 1883 to the National Academy of Design, of which he was president in 1899-1909. Under his able administration the Academy expanded, and its influence greatly increased. As professor of drawing in the College of the City of New York after 1903 and director of the Art Schools of Cooper Union he exercised an important educational influence, and he also took a prominent part in movements to promote art, such as the Fine Arts Federation of New York, of which he became president. He was elected a member of the National Institute of Arts and Letters.

DIELS, dēls, HERMANN (1848-). A German classical scholar, appointed professor ordinarius of classical philology at the University of Berlin in 1886. He was born at Biebrich on the Rhine and was educated at the universities of Bonn and Berlin. In addition to his most notable work, *Doxographi Graeci* (1879), in which the sources of the doctrines of Greek philosophers as transmitted by post-Aristotelian scholars were for the first time determined, his works include an edition of Simplicius' *Commentary on the Physics of Aristotle* (*Simplicii in Aristotelis Physica Commentaria*, 1882); *Ueber die Philosophenschulen der Griechen* (1887); *Die Fragmente der Vorsokratiker, Griechisch und Deutsch* (1903; 2d ed., 1906-10); and a treatise on the *Sibyllinische Blätter* (1890). He was one of the editors of the *Archiv für Geschichte der Philosophie* (Berlin), begun in 1887, and of the *Commentaria in Aristotelem Graeca*.

DIEL/YTRA. See DICENTRA.

DIÉMER, dyä'mär', LOUIS (1843-). A French pianist and composer, born in Paris. He studied at the conservatory under A. Thomas, Marmontel, Benoist, and Bazin, carrying off the first prize for piano playing when only 13 years old. In 1888 he succeeded Marmontel as professor of piano at the conservatory. His series of historical piano recitals during the Exposition of 1889 created such widespread interest that he devoted himself almost exclusively to the older piano music and founded the Société des anciens instruments. He published a valuable collection of *Clavichordistes français*. His original compositions include a piano concerto in C m., a concertstück for piano and one for violin, some excellent chamber music, and numerous works for piano.

DIEPENBEECK, dē'pen-bäk, ABRAHAM VAN (1596-1675). A Flemish painter and designer for line engravings and stained glasses. He was

born in Bois-le-Duc, studied under his father, a glass painter, and came to Antwerp about 1623. There he designed a number of important glass windows, some of which survive in the cathedral of Antwerp, St. Jacob's Church, and elsewhere. In 1641 he was elected dean of St. Luke's Guild, Antwerp. Many pictures in various museums and churches have been ascribed to him, but only two (the "Martyrdom of St. Julia," and the "Virgin of the Apocalypse" in the Uffizi, formerly attributed to Van Dyck) are absolutely authentic. Others, such as "St. Norbert," in the cathedral at Antwerp; the "Consecration of St. Norbert" in the church of Deurne, and the "Distribution of Alms" (Pinakothek, Munich), are probably by him. On the other hand, the "Flight of Clœlia" and the "Marriage of St. Catharine," in Berlin, and kindred paintings, formerly attributed to him, are repudiated by modern critics. He made numerous drawings for the Duke of Newcastle and painted his portrait, from which it is assumed that he visited England. He was connected with the Plantin printing establishment and designed about 500 plates of a rather inferior quality.

DIEPPE, dyĕp (connected with AS. *dype*, Dutch *diep*, depth). A seaport in the Department of Seine-Inférieure, France, at the mouth of the river Arques, on the English Channel, 33 miles north of Rouen (Map: France, N., G 3). Dieppe is situated between two high ranges of chalk cliffs, and is a fairly modern city; the houses are built for the most part of stone and brick, with high, slanting roofs. The fifteenth-century castle, now used as a barracks, occupies a high cliff at the west end of the town. The old harbor is situated to the northeast, and admits vessels of 500 tons' burden, but a new channel with its own harbor system has been added, and vessels of 20-foot draft can now enter. Connected by a drawbridge is the little fishing suburb of Pollet, uninviting, but interesting in that the inhabitants, differing from the rest of Upper Normandy, are supposed to be descendants of Saxons who settled on the French coast during the Merovingian period. Among the principal buildings are the churches of Saint-Jacques of the twelfth century, and Saint-Remy of the late sixteenth century, a museum and picture gallery, and the theatre. Dieppe is one of the principal watering places of France and attracts many visitors in summer. It has a communal college and a school of navigation. It is one of the chief import points for English coal. It has daily steamer service to Newhaven on the English coast. The manufactures are lace, cotton goods, porcelain, lumber, fine linen, tobacco, paper and carved articles of horn, bone, and ivory. There are also ship-building yards, sugar refineries, and distilleries. The fishing fleet of Dieppe is large and important. Pop., 1901, 22,839; 1911, 23,973. In 1442 Dieppe held out successfully against a besieging force of English under Talbot. Its merchants were early noted for their enterprise, and ships from this port visited Brazil and the East Indies in the sixteenth century. In 1694 it was bombarded by the English and Dutch fleet and utterly demolished. Since that time it has been outdistanced as a port by Havre. Consult *Guide au Dieppe et environs* (Dieppe, 1865), and D. Asseline, *Les antiquités et chroniques de la ville de Dieppe* (Paris, 1874).

DIERVILLA, di'ĕr-vil'la. See WEIGELA.

DIERX, dé'ĕr', LÉON (1838-). A French poet born on the island of Réunion and educated at Paris. He became a member of the Parnassians. He published: *Aspirations* (1858); *Poèmes et poésies* (1864); *Les lèvres closes* (1867); *Les paroles du vaincu* (1871); *La reconte* (1874); *Les amants* (1879). His collected poems (1889-90) were crowned by the Academy.

DIES AND DIE SINKING (OF. *de, det*, Fr. *dé*, Sp., Portug., It., *dado*, die, from Lat. *datus*, p.p. of *dare*, to give). The art of making and using dies for stamping coins is of very ancient origin. Old coins have been found which show that it was known to the Greeks at least 800 B.C. The use of dies for stamping, shaping, and cutting out metals and other materials is of much more recent origin and reached its present development only in the closing years of the eighteenth century. The use of the punch and press for cutting metal forms is said to have been practiced in a crude way by a German blacksmith of the fifteenth century. Presses for shaping as well as cutting metal were invented by T. Griffiths, of England, in 1841, but they were developed in France, where they were applied to the production of kitchen utensils. More recently presses have been utilized in many other branches of manufacture besides those dealing with metals. The use of dies, e.g., plays an important part in the modern shoe factory and, in fact, in all industries where a given form has to be produced repeatedly, whether the material be metal, leather, cloth, or paper. The most recent development in the art of using dies has been in the direction of working cold steel into numerous complicated forms, which were formerly produced only by casting and forging.

The astonishing cheapness of numerous sheet-metal products is mainly due to the use of dies, which accomplish by a single stroke the work which formerly required long and tedious manipulation. A striking example is the modern bicycle or typewriter, a large proportion of whose many hundred parts are formed by the power press. Not only kitchen utensils, but jewelry, boxes, pens, buttons, and the thousand and one familiar objects which were formerly worked into shape with the hammer, or soldered together out of separate pieces, are now struck between two dies of suitable form.

Dies, in general, are in pairs, consisting of a male die, or punch, and a female die, which are so adjusted on a power press that one fits accurately into the other. Often, however, in cutting the less resistant materials, as leather, cloth, or paper, the two parts of the typical die are not required. The punch is simply forced by a power hammer through the materials against a flat surface. In an article in the *Engineering Magazine* (New York) for March, 1898, on "The Development of Machinery for Sheet-Metal Stamping," Oberlin Smith divides the kinds of work done by stamping into four general classes: "(1) cutting, in which are included punching and shearing; (2) forming, including bending, embossing, and curling; (3) drawing and redrawing, which are more than forming, since the metal is subjected to an extensive distortion or molecular flow, incident to the changing of a flat, annular disk into a cylindrical, or conical, or hemispherical form of smaller average diameter, its surface being meanwhile rigidly confined to prevent

wrinklings; (4) coining, with which should be included drop forging, the metal in both cases being treated as a liquid and simply pumped, as it were, into the shape desired, the molecular flow being very great, and the whole object being treated as is a pat of butter or a cake of soap in the molds provided for its new incarnation."

The simplest forms of cutting dies are the *blanking dies*, used for cutting out flat blanks from steel, iron, or other material. A shear edge is given either to the punch or to the die, according to the work to be performed. When, as in cutting buttons, it is the blanks that are to be used, the shear edge is given to the die; but when the hole is the object sought, as in making rivet holes in boiler plates, the shear is given to the punch. *Compound cutting dies* are used for cutting fine work, where the relation of the centre or other holes to the outside must be perfect, as in blanks for watch and clock movements, and sheet-iron disks for the armatures of dynamos and electric motors. A compound die has for its upper half a punch set into a die and for its lower half a die set into a punch; one stroke of the press thus performs the work that would require two or more operations if done on plain dies. *Needle dies* are used for punching eyes in needles. The die is made in three pieces, securely fastened together. The centre piece projects above the surface of the two side pieces and into the groove of the needle. Thus, the needle is supported while being punched. This centre piece has a U-shaped slot, equal in width to the length of the eye of the needle. The press is so arranged that the needle is first stamped and then punched, the speed of the punch at the moment it enters the eye of the needle being very slow.

Bending dies are simple when the metal is bent at a single angle, and complex when a loop is required, as in making armature connections, safety pins, and the like. *Drawing dies* are dies which are used for "drawing up" or shaping metal into such forms as basins, thimbles, and bells. In some complex dies the metal is shaped, stamped with a design, and cut, all by a single stroke of the press, as in making blacking-box covers. Very often, however, in producing the more complicated forms of drawn work, the object is put through several dies before it attains its completed shape. The crank hanger of an ordinary bicycle has to pass through a dozen or more presses before the flat sheet of steel is transformed into the piece of complicated tubing required. But even then the process of cutting and bending cold steel by means of power-driven dies is much less expensive than the old method of forging such parts roughly into shape, drilling out the cavities, and turning and polishing the surfaces.

Considering now the use of dies for stamping figures on metallic surfaces, as coins and medals, it is found that the preliminary process of die sinking is an elaborate one. It requires great skill and gives opportunity for the display of artistic feeling and talent as well. Die-sinking is a branch of engraving, but it involves the use of other tools besides those of the engraver. A piece of softened steel, called the hub, is prepared, and on its end the design is cut. The steel is then hardened and forms the *matrix*. The design on the matrix is impressed upon another plug of softened steel,

with the result that the design, wrought in intaglio on the matrix, comes out in relief on the second piece of metal, which is called the *punch*. The punch, in turn, is hardened and used to impress the design upon a third piece of metal. This third piece is of course an exact duplicate of the matrix and forms the die to be used for stamping coins. The original matrix upon which the design was engraved is not used for stamping coins, because the expense of engraving is very great, and the life of a die is short, but is saved for making more dies. One step in the process outlined may be saved by engraving the design, in relief, in the first place so that the punch made from this design in intaglio can be used as a die for coining or

Consult: Lucas, *Dies and Die Making* (Providence, R. I., 1897), a practical treatise on making dies; Woodworth, *Dies: Their Construction and Use* (New York, 5th ed., 1907); id., *Drop Forging, Die Sinking and Machine Forming of Steel* (ib., 1911). The article by Oberlin Smith (see above) contains an admirable résumé of the results obtained by this method of m MINT.

DIESEL, dē'zel, RUDOLF (1858-1913). A German inventor, born in Paris. He studied in England and at the Polytechnic School in Munich, where, after an interval as manager of a Paris refrigerating company, he settled (1895). In 1893 his proposal to utilize directly the energy created by the combustion of fuel created a sensation, and although his plan was proved impractical, yet it led to his invention of the Diesel engine (see INTERNAL-COMBUSTION ENGINES), the success of which he demonstrated in 1897. He lectured in the United States in 1912 and in 1913 was called to England for consultation with the British Admiralty on the application of his motors; but in crossing the Channel he was drowned. There is a translation by Bryan Donkin from the German of Diesel's of 1893 under the title *Theory and Construction of a Rational Heat Motor* (1894). Diesel also published *Die Entstehung des Dieselmotors* (1913).

DIESEL ENGINE. See INTERNAL-COMBUSTION ENGINES.

DIES FASTI. See FASTI.

DIES FISSI. See FASTI.

DIES INTERCISI. See FASTI.

DIES IRÆ, d'ēz Yrē (Lat., day of wrath). The name generally given (from the opening words) to one of the most famous mediæval hymns. The first 17 of its 19 stanzas are in triplets of rhyming trochaic tetrameters; it describes the Last Judgment in language of magnificent grandeur and then passes into a plaintive plea for the souls of the departed. The first stanza is—

"Dies iræ, dies illa,
Solvat sæculum in favilla:
Teste David cum Sibylla."

Daniel, who calls it "the chief glory of sacred poetry," and other eminent authorities agree in assigning its authorship to the Franciscan Thomas of Celano (died c.1255). It found its way gradually into various diocesan missals and was prescribed for universal use in the revised edition of the Roman missal put forth by Pius V in 1570. It is one of only five sequences which have been retained in modern usage and

is sung on All Souls' Day and at other masses for the dead. It was translated into English by Crashaw and Dryden in the seventeenth century and by Macaulay, Isaac Williams, Dean Stanley, and others in the nineteenth. There are said to be 234 English renderings. Perhaps the best version, as well as the most familiar, is that by W. J. Irons. Scott introduced the opening stanzas into his "Lay of the Last Minstrel," and an effective use, heightened by Gounod in his opera, is made of it by Goethe in *Faust*.

DIESKAU, dē'skau, KARL WILHELM (1701-77). A German soldier, born at Dieskau. He entered the artillery in 1721, fought in 12 campaigns, and rose to be a lieutenant general. He made many important improvements in the artillery and under commission of Frederick the Great invented a light cannon known by his name. Consult the *Biography* by Meier (Berlin, 1889).

DIESKAU, LUDWIG AUGUST, BARON (1701-67). A German officer in the French service, distinguished in the French and Indian War in America. He was born in Saxony, was an adjutant to Marshal Saxe, served under him in the Netherlands, and in 1748 was raised to the rank of brigadier general. In 1755 he went to America as major general, to command French troops in the French and Indian War, and in August took the field at the head of 3573 men. Early in September he started for Fort Lyman (afterward Fort Edward) at the head of 216 regulars, 684 Canadians, and about 600 Indians, but afterward changed his plans and moved against Fort George. On September 8, 3 miles from Fort George, he ambushed and completely defeated a detachment of 1000 men sent against him; but, deserted by the Indians and many of the Canadians, he was himself totally defeated before the fort by the terrible fire of a force of English colonists under Sir William Johnson. He was wounded, taken prisoner, held until 1763, and died of the effects of the wound. For his military career in America, consult Parkman, *Montcalm and Wolfe* (2 vols., Boston, 1884).

DIES NEFASTI. See **FASTI**.

DIES NON, dī'ez nōn (Lat., abbreviated from the phrase *dies non juridicus*, not a court day). A nonjuridical day, i.e., a day on which the business of the courts in the administration of justice cannot lawfully be carried on. At the common law Sundays and certain other peculiarly sacred days were of this character, as Ascension Day, All Saints' Day, Christmas Day, etc. In the United States certain secular holidays are included in the description of nonjuridical days, as well as Sunday, but not all legal holidays, nor all days on which the courts do not sit. A day may be juridical, i.e., open to legal process and the administration of justice, even though it be a legal holiday in the usual acceptance of that term, and the courts be not regularly in session. Christmas Day is universally a *dies non*, and in some jurisdictions Thank-giving or Fast Day and Independence Day. But the day of the general election, the Saturday half-holiday, and "bank holidays" generally are law days. Nor does the fact that certain legal acts, as the giving of a promissory note or its presentment for payment, are prohibited on a certain day affect its juridical character. It is only the virtual suspension of the operations of justice which gives a day

the character of a *dies non*, and the policy of the law does not favor the multiplication of such days.

But this paralysis of judicial administration has never been complete. There have always been exceptions to the rule, even in the law courts, and in the early history of equity jurisdiction the chancellor was restrained only by his own sense of what the sanctities of a holy day seemed to require. To-day the equitable as well as the common-law jurisdiction of the courts is suspended on nonjuridical days, and ordinarily there can be no valid issue or service of process of any kind on such days; but it is everywhere held that the court may sit for the purpose of receiving the verdict of a jury, and that warrants for treason, felony, and breach of the peace may issue and be executed on any day; and in general, when public policy or the prevention of irremediable wrong requires it, the courts may sit on Sunday or any other nonjuridical day and issue process.

While the doctrine under consideration is of common-law origin, it is now mainly regulated by statute, and the laws defining it usually declare in express terms what juridical acts can and what cannot be lawfully performed on a *dies non*. As to the distinction between judicial and ministerial acts performed on such a day, consult 9 Coke's *Reports*, 66, and 5 *Central Law Journal*, 26. On the general subject consult 7 *Southern Law Review*, N. S., 697. See also **DAY**; **HOLIDAY**; **SUNDAY**.

DIES RELIGIOSI. See **FASTI**.

DIESTERWEG, dē'stēr-vāk, FRIEDRICH ADOLF WILHELM (1790-1866). A noted German educator. He was born at Siegen, Prussia, and in 1808-11 studied at Herborn and Tübingen. He taught at Mannheim and at Worms until 1813, was called to the Model School at Frankfurt, was rector of the Latin School, Elberfeld, and in 1820 became director of the new Teachers' Seminary at Mörs, where he laid the foundation of his great reputation as a teacher and educational writer. This led to his appointment, in 1832, as director of the Seminary for City School Teachers in Berlin, from which post he retired in 1847, after having for years been involved in serious disagreements with the authorities regarding his reformatory views in connection with the most important phases of higher education. He was pensioned by the government in 1850 and thenceforth propagated his ideas only by his literary efforts. He was elected to the Prussian Diet in 1858. Diesterweg stands in the foremost rank among modern educators and has rendered much service to education by his training of teachers. As a follower of Pestalozzi, he aimed at making every subject of instruction a means of education and by his own example as well as through his writings has exercised a far-reaching influence on the development of his method in the various branches of instruction. He advocated his pedagogical views in the *Rheinische Blätter für Erziehung und Unterricht*, founded by him in 1827, and afterward also in the *Pädagogisches Jahrbuch*, which he established in Berlin in 1851. Among his numerous writings some of the most noteworthy are: *Wegweiser zur Bildung für deutsche Lehrer* (2 vols., 1834; 6th ed., 1 vol., 1890); *Das pädagogische Deutschland* (1836); *Streitfragen auf dem Gebiete der Pädagogik* (1837); *Leitfaden für den Unterricht in der Formlehre*

(1845); *Lehrbuch der mathematischen Geographie* (1840: 18th ed., under new title, *Populäre Himmelskunde*, 1891); *Unterricht in der Kleinkinderschule* (5th ed., 1852). Consult: Adolf Rebhuhn, *Briefe Adolf Diesterwegs* (Leipzig, 1907); Otto Gerstenhauer, *Adolf Diesterwegs Wegweiser zur Bildung für deutsche Lehrer* (Breslau, 1908); Karl Richter, *Adolf Diesterwegs Ansichten über pädagogische Zeit- und Streitfragen* (Leipzig, 1913).

DIET (OF. *dieta*, Fr. *diète*, It., Portug., Sp. *dieta*, from Lat. *dieta*, Gk. *diaita*, *diaita*, daily regimen). The food substances habitually taken into the body, so as to repair the waste of tissue and provide for growth and development. The diet of different human races is quite different in character. The Eskimos, the Kirghiz, and certain other tribes live exclusively on meat. On the contrary, the Hindus and others subsist almost exclusively upon vegetables. But the most intellectual and successful of the human races have lived on a mixed diet. In health the diet should be composed of both easily digested food and food difficult of digestion, to be varied according to the amount of exercise taken, the climate, and the occupation.

Diet in Health. The standard of Voit, of Munich, has long been accepted as the daily diet most suitable to a healthy man of average requirements, doing an average amount of work: 118 grams of proteids, 56 grams of fat, and 500 grams of carbohydrate, to which must be added 30 grams of salt and 3 liters of water. Chittenden has demonstrated, however, that from 5 to 9 grams of proteids a day preserves the nitrogen equilibrium for college professors, members of the United States Army Hospital Corps, and for trained athletes actually competing in contests.

In estimating the available quantities of these nutrients in a given article of food, it is of course necessary to take into account the factor of digestibility. See **Food**.

Diet in Institutions for the Insane. Dr. Austin Flint, of New York, prepared for use in the State hospitals for the insane a diet list which has met the requirements of such institutions for many years, with some modifications according to special indications at certain seasons or in certain localities, and supplemented with special diet in cases of special need, as determined by the physicians in charge. According to this, the following is the daily allowance for each individual:

Meat with bone, including salted meats, fresh and salted fish, and poultry	12 oz.
Flour, to be used in making bread and in cooking (may in part be substituted by cornmeal and macaroni)	16 oz.
Potatoes	8 oz.
Milk	8 oz.
Two eggs	4 oz.
Sugar	2 oz.
Butter	2 oz.
Cheese	2 oz.
Rice, hominy,	1½ oz.
Beans or peas	1½ oz.
Coffee (green)	1 oz.
Tea (black)	½ oz.

Diet in Old Age. In old age there is less demand for food to provide energy, and consequently less nourishment should be taken. It is generally agreed that, given a fair constitution, the use of a physiological diet promotes longevity, freedom from serious illnesses, such as gout, rheumatism, and kidney disease, and a

comfortable existence. The excretory functions are considerably less active in advanced age, and the diet must be modified accordingly. As a general principle, it may be stated that the total amount of food should be restricted, and the food taken should be simple and nutritious, and an excess of animal products avoided. Old people are peculiarly liable to flatulence, and therefore the carbohydrates (starches and sugars) must be taken in moderation. Food should be taken at short intervals and should admit of easy mastication. Following is a sample menu for a normal individual over 60 (Watson):

6 A.M. Cup of tea freshly made; nothing to be eaten with it.

Breakfast: 8.30 A.M. A small cup of tea or coffee; eggs or fish cooked in various well-known ways. Breadstuff should not be hot rolls or indigestible new bread.

Luncheon: 1 or 1.30 P.M. Fish and a farinaceous pudding; or, fish and biscuits and cheese. It is, in most cases, better to reserve the meat or fowl to the evening meal.

Dinner: 7 P.M. Should generally commence with a little soup—a vegetable purée or a good fish soup. Fowl or game, red meat only occasionally, and one vegetable. Pudding of a light farinaceous variety, or stewed fruit.

10 P.M. A cup of consommé, beef tea, or chicken tea, with a thin slice of toasted bread.

Diet in Disease. In disease the activity of digestion is generally lessened, and there is a total waste or loss from the body of certain tissue constituents which in health are replaced as rapidly as they are excreted. In chronic disease the preservation of nutrition is of great importance from the start, and the highly nutritious foods are of the most value, varied from time to time as strength and appetite demand. In acute disease, with prostration, withdrawal of nitrogenous food is generally necessary, together with a diminution of starches and sugars and an increase of fats. In acute processes, accompanied by inflammation, as well as in fevers, serious changes occur in the constitution of the solids and fluids of the body. Interstitial fat disappears; muscles become pale and relaxed, and their contractibility is partially lost; digestion becomes impaired and remains either feeble, abnormal, or suspended; food is imperfectly prepared for assimilation and enters the blood in improper condition: the blood suffers alteration; the urine is found to contain an increase of urates and often also uric acid; the excretion of phosphates is increased, and that of chlorides is diminished; while in the tissues imperfect metamorphosis occurs, pathological materials being stored in them, together with waste products awaiting elimination, and a granular disintegration, or parenchymatous degeneration, may follow. The importance of a properly modified diet is obvious. In such cases milk forms the best diet, to the exclusion of all other food, and about six ounces of milk should be given to the patient every two or three hours, unless vomiting be present. Broths and soups possess very small value as food, but may be given in addition to the proper amount of milk for the sake of variety and to avoid the occurrence of a disgust for milk. With the fall of temperature the simpler solids are administered by degrees, beginning with soft-cooked eggs, green vegetables, oysters, etc. Beef tea is of very slight

value, and in no case should reliance be placed upon it as nourishment. When patients cannot take milk, peptonized combinations of beef, milk, and gluten may be substituted for it.

In disease of the digestive organs skim milk is of the highest value. Buttermilk, or sour milk, prepared artificially with the lactic acid bacillus or *Bacillus bulgaricus*, is of immense value as a substitute for sweet milk in children's summer digestive disturbances and in intestinal fermentation in adults. If acute and confined to the stomach, such disease is best combated if easily digested aliments are administered, as milk and limewater, whey, barley water, etc. In chronic affections of the stomach, with feeble digestion owing to deficiency of the gastric juice, the following articles of food will be found desirable: boiled rice, tapioca, arrowroot, biscuits (crackers), and farinaceous vegetables. Where fermentation of starchy and fatty foods occurs, these must be omitted from the diet, and in their stead acid fruits and vegetables, such as apples, peaches, tomatoes, tamarinds, oranges, etc., should be eaten. In intestinal indigestion and summer diarrhœa starches and fats should be omitted from the dietary, and milk, eggs, animal broths, broiled beefsteak, oysters, and fresh fish are suitable. Habitual constipation due to torpor of the muscular layer of the intestine may be relieved by a diet of cereals, whole-wheat bread, fruits, and green vegetables, with liberal quantities of water.

In many diseases particular diets are requisite. In *diabetes*, e.g., all sugar and sugar-producing food must be withheld, while animal food and fats must be administered in abundance. Water must be drunk freely. Saccharin must be substituted for sugar. The patient may therefore take meat soups; fresh fish, lobsters, and crabs; fat meat, poultry, kidneys, sweetbreads, ham, tongue, sausage, and all kinds of game; pickles, sardines, olives, celery; gluten bread, gluten rolls, gluten mush, almond bread and cakes, bran cakes; all green vegetables, nuts, acid fruits, cream custards, cheese, jellies, ice cream (made with saccharin), tea and coffee, koumiss, skim milk, red wine, mineral waters. All flour must be

carefully avoided. In *Bright's disease* the patient must avoid overfeeding and must take easily assimilated food that leaves a small amount of nitrogenous waste material. He may take soup made of arrowroot, milk, and rice, tapioca, or vermicelli; fresh whitefish, raw oysters and clams; very little red meat; chicken, game, fresh pork, bacon and ham; eggs sparingly; wheat bread, hominy, oatmeal, gruels, toast; green vegetables, well cooked; mushrooms, rhubarb; simple decoctions of milk and rice or of bread; stewed fruit; laxative raw fruits, fruit jellies; milk, koumiss, barley water, buttermilk, and mineral waters; very weak tea. In *tuberculosis* the patient should eat as much as can be digested, mostly of fatty and nitrogenous foods, taking food between meals and at bedtime, and thus receiving some food every three hours during the day. He may take soups; fresh fish and oysters; all meats not smoked or salted, except pork; eggs in all forms except fried; breads with an abundance of butter; all green vegetables, no roots, no potatoes; fats and olive oil; fruits, cheese, farinaceous desserts; milk, cream, cocoa, koumiss, Vichy water, lemonade, mineral waters, and stimulants as ordered by the phy-

sician. It is imperative that food prepared for invalids should be well cooked. The taste and appetite are not trustworthy guides in sickness, but odors, flavors, and dainty serving should be considered. Food should be served very hot or very cold; seasoning, except with salt, should in general be avoided; and small quantities should be offered at a time, with scrupulous care that utensils and linen be clean.

Diet in Convalescence. In acute illness the digestive tract is weakened temporarily, and the patient undergoes a species of starvation. During convalescence caution has to be observed in feeding the young and vigorous, since the appetite returns before digestive vigor is re-established. In typhoid fever, especially, it is dangerous to advance too rapidly, since a mass of undigested food may cause a relapse by setting up irritation in partially healed intestinal ulcers. The fever diet should be gradually reinforced by thickened beef tea, soup, egg drinks, and various jellies; this is followed by the easily digested starches, together with lightly cooked eggs, custards, milk puddings, toast, etc.; then fish, sweetbreads, chicken, chops, and other meats are given in small quantities, and lastly vegetables and fruits will be added to the dietary. The period of convalescence from most fevers may be considered roughly as seven days.

Many forms of diet have been advanced by faddists in the way of cures. Among these may be mentioned the following:

Vegetarianism is a term loosely applied to restricted dietaries which have for their object the exclusion of flesh food. The strict vegetarian relies solely on vegetables grown in the soil and fruits. The *fruitarian* or *lacto-vegetarian* diet includes certain animal foods, such as milk, cheese, eggs, vegetables, fruits, cereals, pulses, sweets, tea, coffee, and cocoa. A variety of this latter vegetarian diet is one restricted to uncooked food. The advocates of this system, first introduced by Christian, hold that the vital principles of food are affected by cooking. The diet consists largely of fruits, nuts, pine kernels specially treated, milk, raw eggs, uncooked vegetables, a particular unfired bread of pressed grains, and some cereals. The distinctive feature of this diet is that it requires thorough mastication.

Purin-Free Diet.—Attention has been recently directed to the advantage of this diet in the treatment of certain chronic diseases, such as gout, neuralgia, headache, and Bright's disease. It is based on the theory that there is in these maladies a retention in the system of uric acid and other purin substances, resulting in chronic poisoning. Purins are bodies constructed on the base $C_5H_4N_4$. The most important are uric acid, xanthin, phyoxanthin, adenin, and guanin. They are derived from animal food (meat, sweetbreads, liver), beans, lentils, and oatmeal. Tea and coffee also contain them. Examples of purin-free foods are milk, cheese, cream, butter, fats, white bread, eggs, apples, grapes, figs, dates, and raisins. Macaroni and nuts are also purin-free. It will be observed that, on the whole, these foods are less appetizing than those containing purin, and overindulgence in them is not likely.

Salisbury Diet.—This is a diet consisting

chiefly of meat and hot water and was advocated for tuberculosis in 1889, when Richet and Hericourt showed the value of raw-meat diet in tuberculosis in dogs. A similar diet was recommended by Dr. Salisbury for the treatment of chronic gout, obesity, gastrointestinal disorders and other disorders of nutrition, attributed by him to carbohydrate fermentation. In its strict form the treatment consists in the administration of one to three pounds of meat and from three to five pounds of hot water per day, for a period of from one to three months.

The Grape Cure.—Among the various forms of fruit diet the grape cure is probably the best known, being recommended for cases of abdominal plethora, chronic bronchitis, emphysema, chronic constipation, and gastrointestinal catarrh. It is extensively practiced in the grape-growing districts of Meran and Montreux and other parts of southern Europe. The cure consists in taking from one-half to one pound of grapes, three-quarters of an hour before meals, the latter consisting of light, easily digested food, such as fish, chicken, milk puddings, stewed fruits, green vegetables, etc., and avoiding rich sauces, pickles, lentils, pastry, cheese, and sweets.

For special diet suitable to very young children, see INFANTS, FEEDING OF; for diets in obesity, see under that title; see also the general article FOOD, and the special articles MEAT, FISH, BREAD, ETC.; MEAT EXTRACT. Consult: Chittenden, *The Nutrition of Man* (New York, 1907); Chalmers Watson, *Food and Feeding in Health and Disease* (ib., 1913); Hindhede, *Protein and Nutrition* (London, 1913).

DIET (etymology same as preceding). A name at present applied to the legislative bodies in the German states, to the provincial assemblies in Austria, and to the Hungarian Parliament. These assemblies are called in German *Landtage*. The German Imperial Parliament bears the name of *Reichstag*, which word, when applied to the representative assembly of the old German Empire (Holy Roman Empire), figures in English works as Diet. The federal assembly of the Germanic Confederation (*Bundesrat*) is also styled Diet in English. The word "Diet" is also applied to the representative assemblies in the old Kingdom of Poland and other countries. The Diet of the Holy Roman Empire was made up of the Electoral College (q.v.), the princes of the Empire, spiritual and temporal (including the counts and other nobles, who voted only by groups), and the delegates of the free Imperial cities. The princes, save in the matter of electing the Emperor, had the same rights as the Electoral College. The powers of the free Imperial cities were quite limited, and were not even formally recognized until 1648. Each of the three colleges voted separately. When they agreed on a measure, it was submitted to the Emperor for ratification or for rejection, but he had no power to modify it. No measure affecting the welfare of the Empire could be passed without the assent of the Diet. The regular meetings were held twice a year, usually in some chief town of the Empire. After the close of the Thirty Years' War the power of the body declined, though it continued to hold its meetings at Ratisbon down to the dissolution of the Holy Roman Empire in 1806. Consult: Bryce, *The Holy Roman Empire* (London, 1871); Waitz,

Deutsche Verfassungsgeschichte (6 vols., Berlin, 1865-96); Turner, *The Germanic Constitution* (New York, 1888).

DIETERICI, dē'tā-rē'tsē, FRIEDRICH (1821-1903). A German Orientalist, born in Berlin. He studied at the universities of Halle and Berlin, traveled extensively in the East, and in 1850 was appointed professor of Semitic literature in the University of Berlin. He won particular distinction by his researches in the Arabic language and literature. The long list of his published works includes: *Alfiyyah Carmen Grammaticum Auctore Ibn Mālik cum Commentario Ibn Akil* (1851); *Mutanabbi Carmina cum Commentario Wahidii* (1858); *Der Naturanschauung und Naturphilosophie der Araber* (1860; 2d ed., 1876); *Die Logik und Psychologie der Araber im zehnten Jahrhundert* (1867); *Die Lehre von der Weltseele bei dem Arabern* (1872); *Die Philosophie der Araber im neunten und zehnten Jahrhundert nach Christus* (1876); *Die Abhandlungen der Ichwān Es-Safā in Auswahl* (1883-86); *Alsarabis philosophische Abhandlungen* (1890); *Ueber des älteste Bekenntnis der Christenheit* (1895); *Muhammad ibn Muhammad 'abū nasr al-Farābī: Die Staatsleitung . . . aus dem Nachlasse . . . F. Dieterici*, ed. by Paul Brönnle (1904).

DIETERICI, KARL FRIEDRICH WILHELM (1790-1859). A German economist. He was an engineer geographer in Blücher's army from 1813 to 1815, was engaged in the Ministry of Public Instruction, became professor of political science in the University of Berlin, and in 1844 was placed at the head of the statistical bureau. He published a number of important works on political economy and statistics, among which may be mentioned: *De Via et Ratione Economiam Politicam Docendi* (1835); *Statistische Uebersicht der wichtigsten Gegenstände des Verkehrs und Verbrauchs im preussischen Staat und im deutschen Zollverband* (1838); *Ueber Auswanderungen und Einwanderungen* (1847).

DIETRICH, dē'trīk, AUGUSTE EDGARD (1846-). A French author, born at Nancy. From an early age he took a special interest in the German language and literature, and was the first to translate two of Max Nordau's works into French under the following titles: *Les mensonges conventionnels de notre civilisation* (1886) and *Le mal du siècle* (1890). He contributed to many French and foreign reviews, such as *La Revue du Nord*, *La Jeune France*, and *Le Messager de Vienne*, and translated Lady Blennerhassett's *Madame de Stael et son temps* (1890). His original publications include: *Les maîtresses de Louis XV* (1881); *Rouget de Lisle et la Marseillaise* (1882); *Jacques Richard et la presse* (1886); *La mort de Danton* (1888). He also edited the *Poésies de Jacques Richard* (1885).

DIETRICH, dē'trīk (also **DIETERICI** and **DIETRICY**), CHRISTIAN WILHELM ERNST (1712-74). A German painter, etcher, and administrator, born at Weimar. He studied under his father, the court painter at Weimar, and under Thiele in Dresden. In 1741 he was appointed court painter at Dresden, in 1748 inspector of art galleries, and in 1764 director of the manufactory of porcelain at Meissen and professor of the Academy of Dresden. In his art Dietrich was a typical eclectic, who imitated every school with great facility, but he showed most understanding of the Dutch. He painted every subject, his religious pictures being the

best. His works are numerous in nearly all German galleries, especially in Dresden with 53 and Schwerin with 56, and in many palaces and churches in Germany.

DIETRICH OF BERN. The name under which Theodoric the Great (q.v.) appears in German heroic legends; by Bern, his capital, Verona is to be understood. With a not unusual disregard of all historical truth, Dietrich was brought into connection with the traditions of Attila, or Etzel. According to these legends, Dietrich is said to have fled from Italy before Ermanaric, or in later poems Otacher (Odoacer), and to have met with a hospitable reception from Etzel. After many years he regained possession of his kingdom. Dietrich appears in the second part of the *Nibelungenlied*, at Etzel's court, and is praised with special predilection. There were numerous other poems in which Dietrich was the central figure, but only late versions of these poems have come down to us. Consult Sandbach, *Heroic Saga-Cycle of Dietrich of Bern* (London, 1906), and Hodgkin, *Theodoric the Goth* (New York, 1891).

DIETRICHSON, dē'trik-sōn, LORENTZ HENRIK SEGELCKE (1834-). A Norwegian art historian. Born at Bergen, he studied at Christiania, was an instructor in the University of Upsala, then spent three years in Rome as secretary of the legation, after which he became an official in the National Museum in Stockholm. In 1869 he became professor in the Academy of Arts at Stockholm and in 1875 professor of the history of art in the University of Christiania. Although taking as his special field the mediæval art of Norway, he wrote much and well on related subjects.

DIETRICH VON NIEM, dē'trik fōn nēm. See NIEM, DIETRICH VON.

DIETSCH, dēch, HEINRICH RUDOLF (1814-75). A German classical scholar, born at Mylau. In 1847-62 he was one of the editors of the *Neue Jahrbücher für Philologie und Pädagogik*. He published a valuable edition of the complete works of Sallust (2 vols., 1843-46; 4th ed., 1874) and a *Versuch über Thucydides* (1865).

DIETZ, dēts, FEODOR (1813-70). A German historical and battle painter. He was born at Neunstetten, Baden, and first studied under Karl and Rudolf Kuntz in Karlsruhe, where he was strongly influenced by Feodor Ivanowitch. He then studied at the Munich Academy, chiefly under Philip Foltz, whom he aided in the decoration of the new royal palace. His first independent effort, "Death of Max Piccolomini" (1835), now in the Karlsruhe Gallery, attracted great attention. He spent three years in Paris, where he was influenced by Horace Vernet, and was awarded the gold medal in the Salon of 1839. He was appointed court painter at Karlsruhe, but returned to Munich, where he produced his best work. He took part as a volunteer in the campaigns of 1848-49 in Schleswig-Holstein, and in 1862 was made professor of the newly created School of Arts at Karlsruhe. He died while serving in the Franco-Prussian War of 1870. His work was often theatrical, but is clear in composition and spirited in treatment. Among his best canvases are: "Nocturnal Review" (1853), acquired by Napoleon III; "The Destruction of Heidelberg by General Mela" (1856), in the Gallery at Karlsruhe; "Flight of an American Family across the Susquehanna," an interesting romantic genre piece (Paris Ex-

position, 1867); "Blücher's March to Paris" (1868), in the National Gallery in Berlin.

DIEU ET MON DROIT, dyē ā mōn drwā (Fr., God and my right). The battle cry of Richard I at the battle of Gisors (1198), signifying that he was not subject to France, but owed his power to God alone. The King was victorious over the French, and the battle word was adopted as the motto on the coat of arms of England. Edward III revived the motto in 1340.

DIEULAFOY, dyē'lā'fwā', GEORGES (1840-1911). A French physician. He was born in Toulouse and studied in Paris. In 1886 he was appointed professor of at the University in that city and in 1890 he became clinical professor at the Hôtel Dieu. In the publication entitled *De l'aspiration pneumatique souscutanée* (1870) he recommended the method of puncturing the thorax discovered by Van den Corput in 1857, for the treatment of pleurisy. Another important work is the *Manuel de pathologie interne* (2 vols., 1882; 16th ed., 1911; Eng. trans. by V. E. Collins and J. A. Liebmann, 1911). His investigations on appendicitis attracted wide attention in medical circles.

DIEULAFOY, MARCEL AUGUSTE (1844-). A French engineer and archaeologist, born in Toulouse. While in Persia in 1885, he discovered at Susa the remains of the palaces of Darius I and Artaxerxes. He brought back to France a quantity of very valuable specimens of Persian architecture, which have a special department in the Louvre, and published an account of his discoveries in the *L'Art antique de la Perse* (1884-89, 5 vols.); and he published also *L'acropole de Suse d'après les fouilles exécutées en 1884-86* (Paris, 1890-92), and *Art in Spain and Portugal* (1914).—His wife, JEANNE-RACHEL MAGRE (1851-), accompanied her husband in these journeys and assisted him materially. Her works include: *La Perse, la Chaldée, et la Susiane* (1887); *A Suse* (1888); and several novels and plays. She was made a member of the Legion of Honor. In collaboration with her husband, she published *Le théâtre dans l'intimité: Nais la Sulamite, farce nouvelle du paté et de la tarte* (2 vols., 1900).

DIEZ, dēts, FRIEDRICH CHRISTIAN (1794-1876). A German philologist and founder of the scientific study of Romance philology. He was born and educated at Giessen, served in the War of Liberation, and later took a supplementary course in philology at Göttingen. In 1830 he was called to the chair of Romance philology at Bonn. The works respectively entitled *Die Poesie der Troubadours* (1826; 2d ed., 1883) and *Leben und Werke der Troubadours* (1829; 2d ed., 1882, by K. Bartsch) soon made him widely known. These and the standard publication entitled *Grammatik der romanischen Sprachen* (1836-42; 5th ed., 1882; Eng. trans. by Cayley, 1863; Fr. trans. by Brachet, Gaston Paris, and Morel-Fatio, 3 vols., Paris, 1874-76) and *Etymologisches Wörterbuch der romanischen Sprachen* (1853; 5th ed. by Von Scheler, 1887; Eng. trans. by Donkyn) obtained recognition even among the Romance nations as works of basic importance. They are written in a clear and concise style, and in them the author has given to the world a classic example of the historical and comparative method of investigation. Consult: Breymann, *Friedrich Diez, sein Leben, seine Werke* (Munich, 1878);

Behrens, *F. Diez* (Giessen, 1894), published in honor of the hundredth anniversary of his birth; Ritter, *Le centenaire de Diez* (Geneva, 1894), which contains unpublished letters of Diez and his friends.

DIFFERENCE (OF., Fr. *différence*, Lat. *differentia*, from *differre*, to differ, from *dis-*, apart + *ferre*, to bear). In heraldry, an addition to or alteration in an escutcheon to mark a distinction between the coats of arms of two closely related persons whose shields would otherwise be the same. Though generally confounded with marks of cadency (q.v.), differences have, in strict usage, a totally different function—the former being employed to distinguish brothers and their descendants after the death of the father, the latter while he is still alive. Differences in this limited sense may consist either of a chief added to, or a bordure placed round, the plain shield borne by the head of the house; or should the shield exhibit any of the ordinaries, as the bend, fess, or pale, the difference may be indicated by an alteration in the lines of the ordinary. The proximity of the bearer to the head of the house is indicated by the character of the line by which the difference is marked off from the field, the following being the order usually observed: the first or eldest brother, on the death of his father, inherits the pure arms of the house; the second brother, if the difference is to consist of a bordure, carries it plain; the third, ingrailed; the fourth, invected; the fifth, embattled; etc. Other modes of differencing have been invented by heralds, and are not unknown to practice—such, e.g., as changing the tinctures either of the field or of the principal figures, of which Nisbet gives many famous examples; altering the position or number of the figures on the shield; adding different figures from the mother's coat or from lands, and the like. Where the cadet is far removed from the principal family, if the field be of one tincture, it is sometimes divided into two, the charge or charges being counterchanged, so that metal may not lie on metal, nor color on color. The confusion between differences and marks of cadency, above referred to, occurs in the heraldic usage of England, Scotland, and the countries of the Continent. In France the cadets of the house of Bourbon have been in the habit of continuing these marks, and at the present day the label or lambel is to be seen on the arms of all the members of the Orléans family. That no distinction between what we call marks of cadency and differences was there observed is further apparent from the fact that, while such was the practice of the house of Orleans, the house of Anjou carried a bordure gules, and that of Alençon a bordure gules with eight bezants. In Germany, according to Sir George MacKenzie, several branches of great families are distinguished only by different crests, because, he says, all the sons succeed equally to the honors of the family. In Great Britain and in France some change is always made on the shield as carried by the head of the house; but the practice even of good heralds has been so lax as to bring the rule very nearly to what it would be if it were the correct one—that every private person should be allowed, with the sanction of the proper authorities, "to make what marks of distinction can suit best with the coat which his chief bears." See **HERALDRY**.

DIFFERENCE. In mathematics, difference usually means the excess of one quantity over another of the same kind, and this is its meaning in arithmetic. In higher mathematics, however, it is used in a special sense in connection with series and functions. Consider the following systems:

Given series	4, 7, 11, 18, 31, 54, 92, 151, 238, . . .
First differences	3, 4, 7, 13, 23, 38, 59, 87, . . .
Second " "	1, 3, 6, 10, 15, 21, 28, . . .
Third " "	2, 3, 4, 5, 6, 7, . . .
Fourth " "	1, 1, 1, 1, 1, . . .

The law of formation is not obvious in the first series, but by successively repeating the process and forming the second differences, and repeating it again for the third differences, a series is found whose law of formation is obvious. Beginning with 7, the sixth term of the third differences, the ninth term of the given series is evidently 238. The general formula for the n th term of such a series is

$$t_n = a + (n-1)b + \frac{(n-1)(n-2)}{1 \cdot 2} \cdot c + \frac{(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3} \cdot d + \dots$$

in which a, b, c, \dots represent respectively the first term of the several series. The sum of n terms is expressed thus:

$$S_n = na + \frac{n(n-1)}{1 \cdot 2} \cdot b + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} \cdot c + \dots$$

Certain calculating machines (q.v.), particularly the difference engine, are constructed on this principle. Out of the method of differences arose the calculus for finite differences. (See **CALCULUS**.) Pierre Raymond de Montmort (1678-1719), François Nicole (1683-1758), and Brook Taylor (1685-1731) were pioneers in this subject.

DIFFERENTIALIZATION. See **CALCULUS**.

DIFFERENTIATION. In biology, the process by which the body becomes more complex by becoming different in its different parts. Both phylogenetically and ontogenetically organisms begin in a relatively simple state; evolution and individual development are both accompanied by specialization of organs and division of labor among the various parts of the body.

DIFFERENTIATION OF ROCKS. A term used by geologists to denote the process by which varied types of igneous rocks develop from a uniform parent mass or magma. Volcanoes at different periods of their activity may erupt lavas of contrasting character, as has hap-

pened frequently in some of the craters in the Mediterranean region; also, bosses of granite, syenite, and other deep-seated rocks often show a considerable range of mineral composition between their interiors and the border zones. These and similar features which have been abundantly attested indicate that a reservoir of fused rock in the earth's interior is subject to successive cleavage or division, by which in place of a homogeneous mass several more or less distinct rock types result. The process of differentiation plays a very important rôle in the derivation of igneous rocks, and it seems probable that the many varieties into which they are divided have really sprung from a few fundamental magmas. The principle underlying the process is not well understood, although much study has been given to the subject in recent years. It is thought by some geologists that the force of gravitation during the crystallization of the magma effects a separation of the lighter and heavier minerals, resulting in the acidic and basic types that are frequently observed in a differentiated rock mass. Other causes of variation have been proposed, such as fractional crystallization, the influence of convection currents, the absorption of foreign material into the magma, and the action of mineralizing agencies, inclusive of gases and heated waters. See IGNEOUS ROCKS.

DIFFRACTION AND DIFFRACTION GRATINGS (from Lat. *diffringere*, to break in pieces, from *dis-*, apart + *frangere*, to break). When shadows are cast on a screen by allowing light from a small opening or source to pass an opaque body, it is noted that the shadows are not sharp, as would be expected if "light traveled in straight lines." Thus, if light from the sun or from any source of light falls upon a large opaque screen in which there is a narrow slit; and if there is placed some distance from this another opaque body with a sharp edge (e.g., a knife blade) parallel to the slit, the shadow of the latter cast by the light from the slit will have several peculiarities. Calling the geometrical shadow the region where there would be darkness if light traveled in straight lines, it will be observed that the actual shadow begins a slight distance within the "geometrical" one—in other words, the light is bent into the latter; further, on the edge of the geometrical shadow, where one might expect uniform illumination, there are series of narrow colored bands, parallel to the edge, i.e., there is first a strip brightly illuminated with one color, then another band with a different color, etc., the colors merging into each other; at a distance of a few millimeters from the edge of the shadow, however, the field is uniformly illuminated. If, instead of having white light as a source, a colored flame is used, e.g., light from a flame containing sodium, the bands outside the geometrical shadow become simply alternations of light of the colors of the flame, and comparative darkness. This phenomenon is called diffraction, and was first observed by Grimaldi, professor in the Jesuits' College, Bologna, in 1665. It was studied later by Newton, but was not explained until Fresnel made his classical research in 1819. Similarly, if light from a pin-hole opening falls upon any opaque object, casting a shadow of it on some suitable screen, diffraction bands may be observed outside the geometrical shadow, following the general contour of the latter; and the light enters slightly

into the shadow. For other cases of diffraction, reference should be made to some treatise on light. One of the best is Preston's *Theory of Light* (London, 1901).

It was shown by Fresnel that diffraction phenomena are explained by the fact that light is due to a wave motion (see LIGHT); consequently diffraction is possible with other waves, e.g., those in air which produce the sensation of sound.

The colors of the feathers of many birds and of mother-of-pearl are due to diffraction; so are the colors seen when one looks at a bright light through a piece of thin cloth. If a great number of fine scratches, evenly spaced, are made on a piece of glass, or on a polished mirror, there is formed a "diffracting grating." The former is called a transmission grating; the latter, a reflecting one. If, as in a previous experiment, white light from a slit in an opaque screen is allowed to fall perpendicularly upon a transmission grating, the slit being parallel to the scratches, the transmitted light will be broken up into spectra, regularly spaced on both sides of the line drawn from the slit to the grating, except in the direction of this line. Thus, if the transmitted light falls upon a white screen parallel to the grating, there will be a central white spot, and on each side of this, along a line at right angles to the lines on the grating, a succession of colored spectral bands. This spreading sideways of the light is due to its diffraction through the narrow, transparent slits between the scratches; and the dispersion of the white light is occasioned by the fact that the amount of diffraction varies with waves of different wave number, i.e., with different colors (see LIGHT). The same phenomena are observed with reflection gratings if the screen is placed on the same side as the slit of light and provided with an opening to allow the light to fall upon the grating.

Gratings are of the utmost importance in spectroscopy (q.v.), as they furnish a means of measuring the wave lengths of ether waves. They were invented and first used by Joseph von Fraunhofer, of Munich, in 1821. To be of value, gratings must be ruled with the scratches at *exactly* equal intervals. This is secured by placing the surface to be ruled on a platform, which is carried forward by a long screw, whose thread is perfectly uniform, and by having a diamond point so arranged as to draw lines at right angles to the direction of the screw. By means of a toothed wheel fastened to the screw it is turned through a definite proportion of one complete revolution, thus carrying the platform forward a definite distance; e.g., if the threads of the screw are at a distance 1-15th of an inch apart, and if the toothed wheel has 1000 teeth, then, if this wheel is pushed round by an amount equal to one tooth, the screw will turn through 1-1000th of a complete revolution and will carry the platform forward 1-15,000th of an inch. Then the diamond is drawn across the surface of the grating, making a groove; it is raised, pushed back to the other side of the grating, dropped down, and again drawn across the surface, the platform in the interval of time, while the diamond is pushed back, having been carried forward another step. The process is continued until as many lines are made as are desired. Such a machine is called a "dividing" or a "ruling" engine. (See DIVIDING ENGINE.) The most perfect gratings now in use have been

made at the physical laboratory of Johns Hopkins University, where Professor Rowland supervised their preparation. His gratings have, as a rule, 15,000 lines or scratches to the inch; and the grating surfaces vary from 2 inches to 6 in width.

To use gratings ruled on plane surfaces for spectroscopic purposes, it is necessary to combine them with telescopes and collimators; but Professor Rowland has shown that reflecting gratings ruled on spherically concave surfaces can be used without the addition of lenses. These "concave gratings" have other marked advantages over plane ones for almost every spectroscopic purpose. A good description of their properties is given in Preston's *Theory of Light* (London, 1901).

DIFFUSION (Lat. *diffusio*, a spreading out, from *diffundere*, to diffuse, from *dis-*, apart + *fundere*, to pour). The gradual dispersion of the particles of one substance among those of another.

Diffusion of Liquids. If sulphuric acid be carefully poured through a tube into the bottom of a vessel filled with water colored by a few drops of litmus solution, and the liquids allowed to remain undisturbed, the acid will be seen gradually to diffuse upward into the water, its progress being indicated by the change of color of the litmus from blue to red. After a sufficiently long time the liquid will be found perfectly homogeneous; i.e., the two layers of acid and water will have completely intermixed, forming a dilute solution of sulphuric acid of uniform strength throughout. A similar process would take place in the case of water and alcohol, and, in general, in the case of any pair of liquids that are at all capable of being mixed together. In many cases, however, the rate of diffusion would be so small that it might take months and even many years before the solutions would become perfectly homogeneous. The reason of this is that the surface of separation of two liquids is, under ordinary circumstances, comparatively very small. To render the diffusion more rapid, the surface through which diffusion takes place would have to be increased; and this is usually attained by *stirring* the two liquids with the aid of some solid object, as a glass rod or a spoon. Diffusion itself, however, is a purely molecular process; i.e., it involves the motion not of *masses* of liquid, but of *molecules*.

Diffusion of Gases. If two flasks be filled, one with hydrogen, the other with chlorine, and connected by a long tube fitted into their necks by means of corks, then, in whatever position the apparatus be placed, it will be found that the gases mutually interpenetrate. The color of chlorine will in this case enable us to follow by the eye the course of the diffusion. When the mixture has attained its permanent state, each of the gases is found to be uniformly diffused through the whole containing space, precisely as it would have been had the other not been present. In fact, the presence of a second gas seems merely to affect the *time* which the first takes to distribute itself evenly throughout the vessel, but in no other way to influence the final result. Dalton long ago suggested the analogy of the passage of water among stones in the bed of a river.

The molecules of gases are capable of passing through solid partitions, which would prevent the motion of masses. The phenomena of dif-

fusion can therefore be readily investigated by measuring the amounts of various gases passing in a given interval of time through a thin layer of bladder or other membrane, or through a thin disk of plaster of Paris, graphite, or biscuit ware. The velocity of diffusion is thus found to be inversely proportional to the density of the gas experimented upon. That lighter gases diffuse more rapidly than heavier ones may be demonstrated as follows: A glass tube, say, 1 inch in diameter, and 2 or 3 feet long, is closed at one end with a diaphragm of plaster of Paris and filled with hydrogen. Its open end is immersed in water, care being taken not to wet the diaphragm. Two processes of diffusion will then take place simultaneously: the hydrogen will diffuse out of the tube into the atmosphere, while the constituent gases of the air will pass through the diaphragm inward. But, as hydrogen is much lighter than the gases of the air, the velocity with which it escapes is greater than that with which the others enter, this being shown by a rise of water in the tube, whose part occupied by gas will continue to decrease until all the hydrogen has diffused out. See also **EFFUSION**.

Diffusion of Substances in Solution. According to modern chemical theory, solid substances in solution exhibit the same phenomena as substances in the gaseous state. Within a given volume of solution a substance exercises, e.g., precisely the same pressure (osmotic pressure) that it would exercise if vaporized and confined within a vessel whose volume is equal to the volume of the solution. This explains the analogy existing between the phenomena of diffusion of gases and the phenomena of diffusion of substances in solution.

Diffusion in solution was discovered in 1815 by Parrot, and was later (from 1850 on) made the subject of a thorough investigation by Thomas Graham. Shortly afterward Fick succeeded in proving, both theoretically and experimentally, that the diffusion of dissolved substances follows a law (Fick's law) precisely analogous to Fourier's law of the diffusion of heat. Accordingly the amount of substance traversing a small distance within the solvent in unit of time is proportional to the area of the cross section through which the diffusion takes place, and to the difference in concentration at the two ends of small distance traversed. The rate of diffusion depends, of course, also upon the nature of the diffusing substances, upon the nature of the solvent, and upon the temperature. At higher temperatures the rate of diffusion is invariably greater than at lower ones.

Solvents resist diffusion more or less, according to their nature; but it is as yet not known how the solvent resistance might in any given case be predetermined from the composition and perhaps other physical properties of the solvent and the diffusing substance. What we do know, however, is how to express in ordinary force units the frictional resistance offered by the solvent, provided we know the concentration of the diffusing substance and have determined experimentally the rate of diffusion. For, according to the modern theory of solutions, it is the osmotic pressure of the diffusing substance that overcomes the resistance of the solvent and drives the substance from points of higher to points of lower concentration, and the magnitude of osmotic pressure is readily ascertained. How enormously great the frictional resistance

of the solvent generally is, may be judged from the following typical case: to move 342 grams (= 1 gram molecule) of cane sugar at the rate of 1 centimeter per second, when the solvent is water and the temperature is 18° centigrade, it would be necessary to employ a force equal to no less than the weight of 4,700,000,000 kilograms.

The influence of the solvent and of the diffusing substance itself is numerically expressed by the so-called diffusion coefficient, frequently denoted by the symbol D . Stefan has shown that in any given case the diffusion coefficient may be determined, in accordance with Fick's law (see above), by using the following simple formula:

$$D = \frac{0.7854A^2}{c^2q^2t}$$

in which A is the amount of substance that has passed into a layer of the pure solvent from a layer of solution in the time t , the concentration of the solution being c and the area of the circular surface of contact of the two layers being q . The formula shows that, in any given case experimented upon, the amount of substance diffusing out of the solution is proportional to the square root of the time. In case the diffusing substance is either an acid or a base the rate of diffusion may be conveniently studied by coloring the pure solvent (usually water) with an indicator, such as litmus, and observing the change of color produced by the diffusing substance as it penetrates farther and farther into the column of pure solvent. In such a case, as shown by Stefan, Fick's law requires that the farthest distance to which the diffusing substance has penetrated must be proportional to the square root of the time that it has taken to get there. Both these theoretical consequences from Fick's law have been tested experimentally by a number of investigators and have been found to hold true, and therefore Fick's law may be considered as proved. In some cases the pure solvent employed (viz., water) was gelatinized by means of agar-agar or similar substances (see COLLOIDS), and Fick's law was still found to hold good. Only, curiously enough, while the amount of substance entering the gelatinized solvent in a given time was found to be exactly the same as if the solvent had been left liquid, the farthest distance to which the substance has penetrated was found to be appreciably less. In one sense, therefore, it may be said that substances diffuse with the same speed in a solvent whether this has been gelatinized or not; in another sense this statement is not true.

The diffusion of electrolytes has been theoretically investigated by Nernst and experimentally by Arrhenius. Electrolytes—i.e., acids, bases, and salts—are dissociated in solution into electrically charged particles, or ions. Each ion has a certain mobility, of its own. Thus, in a solution of hydrochloric acid the free hydrogen ions have far greater mobility than the chlorine ions. It might therefore appear as if the hydrogen ions ought to diffuse out of such a solution at a rate of their own, leaving the sluggish chlorine ions behind. As a matter of fact, however, the separation of positive and negative ions by diffusion would set up an enormous electrostatic attraction between the different parts of the solution, and

this would at once bring the different ions together again. In other words, while the positive and negative ions are in many ways free and independent of each other, they cannot enter upon independent courses of diffusion: the more mobile ones will hasten the progress of the less mobile ones by pulling them along; their own progress will thereby be retarded, the more sluggish ions holding them back. Taking into account both the separate mobilities of the ions and their modification by mutual electrostatic attraction, Nernst has shown that the resultant diffusibility of the electrolyte as a whole is expressed by the following formula:

$$\frac{1}{D} = \frac{1}{2RT} \left(\frac{1}{U} + \frac{1}{V} \right)$$

where D is the diffusion coefficient of the electrolyte as a whole; U and V are respectively the mobilities of the positive and negative ions; T is the absolute temperature (i.e., the centigrade temperature + 273°), and R is the so-called gas constant. The gist of this formula of Nernst's may be expressed in words by saying that the resistance encountered by the diffusing electrolyte as a whole is proportional to the sum of the resistances encountered by the separate ions. Experiment has borne out this proposition very well.

When a substance in solution is dissociated, not electrolytically, but chemically (see DISSOCIATION), matters are quite different: the products of dissociation exert comparatively little influence upon one another, and each diffuses almost independently of the rest. In the case of ordinary alum, e.g., it is thus possible to effect at least a partial separation of the component sulphates, because these have different diffusibilities. Colloidal substances, like albumen, are altogether left behind by crystalloids, owing to great differences of diffusibility, and therefore diffusion may be employed to render colloids perfectly pure (i.e., free from the more mobile crystalloids). See COLLOIDS.

Diffusion of Solids. The diffusion of solid substances through one another is shown by a number of phenomena. Not to speak of the even distribution of a gas through a mass of platinum or palladium, the surface of which has been exposed to the gas, solid carbon is known to be capable of passing through porcelain and to distribute itself evenly in a mass of iron. Further, solid barium sulphate and solid sodium carbonate have been shown to react with each other chemically—a process which could hardly take place unless the molecules of the two substances became intimately intermixed by diffusion. Finally, experiments have been carried out on the diffusion of gold into lead at ordinary temperatures. At 18° C. gold has been found to diffuse upward, and after a lapse of four years traces of gold could be found at a distance of 7 millimeters from the surface of contact.

DIGALLIC ACID. See TANNIN.

DIGAMMA (Lat., Gk. *διγάμμα*, from *δι*, double + *γάμμα*, gamma). The name given by grammarians not earlier than the first century A.D. to Vau, anciently the sixth letter of the Greek alphabet. The name is due to the form, double gamma, *F*. In the Ionic alphabet it was almost completely lost at a very early date, save as the numeral 6; the Chalcidian alphabet, however, retained it, and transmitted it.

through Cumæ, to the Latins, with whom it lost its original sound (approximately our *w*), and became *F*. Even where it had ceased to be written, as in the Homeric poems and in Hesiod, its influence can be detected; in inscriptions it appears frequently in many dialects. Often the cognate words in other languages than Greek show it; e.g., *vinum* = *Foivos*, wine. Consult Buck, *Introduction to the Study of the Greek Dialects*, pp. 43-48 (Boston, 1910). See GREEK LANGUAGE, *Alphabet and Pronunciation*.

DIGBY. A port of entry and popular summer resort, capital of Digby Co., Nova Scotia, on Digby Basin, an arm of the Bay of Fundy and 43 miles southeast of St. John, New Brunswick (Map: Nova Scotia, D 4). It has fishing and lumber industries, a long pier, good bathing, boating, and fishing facilities, and a special reputation for a variety of small herrings or pilchards, known as "Digby chickens," which are cured for export. The United States is represented by a consular agent. Pop., 1901, 1150¹; 1911, 1247.

DIGBY, GEORGE, second EARL OF BRISTOL (1612-77). An English legislator. He was born in Madrid, studied at Magdalen College, Oxford, was a member of the Long Parliament, and was one of the foremost opponents of Strafford. He was extremely vacillating by nature, and, with Pym and Hampden, espoused the royal cause and was taken from the Commons and put in the House of Lords. Apparently he suggested to the King the arrest of the five members. In the Civil War he was lieutenant general of the royal army. During the Commonwealth he lived in France, where he became lieutenant general, but was dismissed for political intrigue against Mazarin. After his return to England he accused Lord Clarendon of high treason. In his last years he seemed to waver in his loyalty to the Roman Catholic church. He wrote the comedy *Elvira; or, The Worst Not Always True* (1667), an adaptation from Calderon.

DIGBY, SIR KENELM (1603-65). An English author and naval commander. He was born three years before the execution of his father, Sir Everard Digby, noted as one of the gunpowder plot conspirators. At the age of 15 he was entered at Gloucester Hall, Oxford. Leaving the university in 1620, without a degree, he traveled abroad. Returning, he was knighted. In 1625 he married the celebrated Venetia Stanley. In 1628 he equipped two ships at his own expense and sailed on a privateering expedition against the French and Venetians in the Mediterranean. He won a victory in the harbor of Iskanderun. In 1632, on the death of Dr. Allen, of Gloucester Hall, Digby inherited his collection of books and manuscripts, which he presented to the Bodleian Library. In the troubles between King Charles and Parliament Digby took the Royalist side, and was imprisoned in Winchester House, but in 1643 was allowed to retire to France. After Charles I had fallen, Digby returned to England, but Parliament forbade him the penalty of death. Retiring to the Continent, he traveled in France and Italy; but in 1655 he was again in England and was in frequent attendance at the court of the Protector. He went again to France and busied himself with the preparation of philosophical papers. He returned to England in 1661 and died there. His works are numerous and on a great variety of subjects,

comprising: *A Conference with a Lady About Choice of Religion* (Paris, 1638); *Observations on Spenser's Faery Queene* (London, 1644); *A Treatise on the Soul, Proving its Immortality* (Paris, 1644); *Of the Cure of Wounds by the Powder of Sympathy* (London, 1658); *Discourse on Vegetation* (ib., 1661); etc. *The Private Memoirs of Sir K. Digby, etc., Written by Himself*, were published in London in 1827. Consult: "Journal of the Scanderoon Voyage," in *Camden Society Publications* (London, 1868); *Poems*, ed. Warner (London, 1877); T. Longueville, *Life of Sir Kenelm Digby* (New York and London, 1896).

DIGBY, KENELM HENRY (1800-80). An English writer. He was born at Clonfert, Ireland, graduated from Trinity College, Cambridge, in 1819, and soon afterward became a convert to the Roman Catholic church. He published many works, chiefly on mediæval theology, or reflecting the spirit of the Middle Ages. The list includes: *The Broad Stone of Honor* (1822); *Mores Catholici; or, Ages of Faith* (11 vols., 1831-40); *Comptum; or, The Meeting of the Ways* (7 vols., 1848-54); *Evenings on the Thames* (2 vols., 1860).

DIG'-DIG' or **DIK'-DIK'** (Arabic). See GAZELLE.

DIGEST. A topical arrangement or compilation of legal rules, judicial decisions, or statutes in condensed form; particularly the authoritative compilation of the civil law, otherwise known as the Pandects, made under the authority of Justinian (530-533). See CIVIL LAW; CODE; PANDECTS.

In English and American law the term is applied to a great number and variety of legal works of reference, ranging from such encyclopædic collections of special treatises as Bacon's and Viner's Abridgments and Comyns's Digest to the alphabetical arrangements of statutes and of case law which have monopolized the title in recent years. The former kind of digest was a favorite form of legal authorship in the earlier period of the common law, and several of these compilations—as those of Statham (about 1470), Fitzherbert (1516), Brooke (1568), and Rolle (1668)—long maintained a high position as legal authorities. The earliest of these are still useful as containing references to cases as yet buried in the Yearbooks and other early reports. As authorities, however, they have all been superseded in the estimation of lawyers by more systematic treatises.

The modern digest of case law is in effect an elaborate index to the enormous collections of judicial decisions in which the common law of Great Britain and of the United States lies embedded. The most authoritative of the English digests are those of Fisher and Chitty. Each American State has one or more of such compilations, of which Abbott's Cyclopædic Digest of New York decisions is perhaps the most extensive and complete. There are also digests of the Federal reports, of the United States statutes, and a comprehensive compilation of all the Federal and State reports, known as the Century Digest. The plan of all these digests of case law is substantially the same, consisting of an alphabetical arrangement of legal titles, under which are given brief statements of the rule or doctrine enunciated in each decision, together with the title and location of the case, in which the decision was rendered. (See ABRIDGMENT; REPORT.) Consult Wambaugh,

The Study of Cases (2d ed., Boston, 1894), and Lindley, "The History of Law Reports," in *Law Quarterly Review* (London, 1885).

DIGESTER. A name originally applied to a strong boiler, with a closely fitting cover, in which bones or other animal substances, placed in water, could be raised to a temperature above the boiling point, or 212° F. The word is now given a wider meaning; the material may be placed in some liquid other than water, and chemical action instead of heat may be used to effect the disintegrating process. The digester, in its simplest form, was invented in 1681 by Denis Papin (q.v.), a French scientist. It is made of iron or other metal, and has an airtight cover, provided with a safety valve, from which steam may be allowed to escape when the pressure becomes too great. The increased pressure to which the contents of the boiler are exposed raises them to a much higher temperature than could be secured in an open vessel, reaching at times 400° F. At such a temperature bones will dissolve. In its modern form the Papin digester is put to much wider uses than the mere preparation of soup and extraction of gelatin from bones, for which it was originally intended. One application of the invention is the lard or grease tank, which is an essential feature of a large modern slaughterhouse. Into such tanks the carcasses of animals too poor for the regular market and the entrails and grease-yielding offal of other animals are thrown. Steam is applied, which resolves the contents of the tank into fat; water, which contains much soluble matter in solution; and mud, containing earthy and solid particles, the contents arranging themselves in layers, from top to bottom, in the order named, according to their specific gravity. The tank is usually a vertical cylinder, with a perforated false bottom, which holds the charge and at the same time allows the water of condensation to percolate into the lower chamber. There is a discharge hole at the bottom for removing the residuum, and a number of try cocks are arranged along the sides, by means of which the level of the fats and water may be ascertained. There may be two discharge cocks; through the higher one the floating fat may be decanted, and through the lower one the water may be drawn off, as the contents and state of the process require. In some forms of digesters, like those for treating garbage, the water and grease may be drawn off together and separated afterward. The solid matter, called *skat*, may be pressed or dried, or both, and is then utilized for various purposes.

A familiar example of a chemical digester is the apparatus for extracting tannin from nutgalls by means of ether. The nutgalls are placed in a vessel saturated with ether; the volatile extract falls into a closed vessel placed below and connected by means of a pipe with the top of the other vessel, to prevent the escape of the ether.

Digesters are used in the hydrolysis of starch to glucose through the agency of hydrochloric or sulphuric acid and in the soda process of making wood-pulp paper.

DIGESTION, COMPARATIVE PHYSIOLOGY OF. See ALIMENTARY SYSTEM, EVOLUTION OF.

DIGESTION (Lat. *digestio*, from *digerere*, to digest), IN PLANTS. The process by which foods are rendered fit for absorption, conduction, or assimilation (qq.v.). Foods are sometimes in-

soluble in water, or, when soluble, need to be altered to make them more readily diffusible or usable. It was formerly believed that, besides carbohydrates of the insoluble type, fats and proteins must be hydrolyzed before translocation is possible. We now know that fats move as such in the form of fine emulsions in case a little free fatty acid and the resulting soap is present. It is possible that peptones and proteins often move as such, the latter in the form of colloidal solutions. Yet that there is a general hydrolysis of fats and proteins in the storage organs of plants is evidenced by the rather general distribution of the necessary enzymes—lipases, proteases, and ereptases.

In general, plants do not possess special digestive organs, but digestion occurs in the cells which contain both storage material and the enzyme. This may be termed endocellular digestion, and stands in contrast to digestion in animals, where the enzyme is generally secreted into a special digestive cavity and extracellular digestion occurs. In insectivorous forms amongst plants true extracellular digestion occurs, and in grass seeds the various enzymes are secreted into the cells of the endosperm by cells of the scutellum and aleuron layer. See SECRETION.

Each prominent food is acted upon by a particular enzyme adapted to transform it. The following table shows the principal sorts of plant foods, the enzymes by which they are digested, and the most important products formed.

I. CARBOHYDRATES

Food	Enzyme	Product
Starch. . . .	diastase. . .	maltose
Inulin. . . .	inulase . . .	levulose
Celluloses	cytase. . .	a variety of sugar
Saccharose	invertase . . .	{ fructose
		{ glucose
Maltose	{ maltase }	{ glucose
	{ glucase }	{ arabinose
Pectins. . . .	{ pectase }	pectic acid
	{ pectinase }	

II. PROTEINS

Albumins, globulins, etc.	{ proteases. . . .	{ proteoses
		{ peptones

III. OTHER FOODS

Glycerides (fats)	lipase. . . .	{ glycerin
		{ fatty acid
Glucosides. . . .	myrosin and emulsin	glucose and various substances

Some of the more prominent examples of digestion may be mentioned. When a fungus lives upon or in a dead or living body, it secretes enzymes which digest such of the substances it comes in contact with as it can attack; these may then be absorbed and used for its nourishment. During the day the leaves of green plants form carbohydrates faster than they can be carried away, and a portion is stored temporarily in the *chloroplasts* (q.v.) as starch granules. Later, and especially during the night, when no food is formed, these starch grains are digested and transferred to places of use or permanent storage. Towards spring potatoes lose their mealiness when cooked, and become gummy and sweetish on account of the digestion of starch into sugar by diastase. When the shoot starts to grow, the process is hastened. In the germination of spores and seeds the stored foods, starch, oils, and proteins, are generally digested by appropriate enzymes, and the materials thus made available for the growing parts.

DIGESTION, ORGANS AND PROCESS OF, IN MAN. The process of digestion is one of the chief of those organic functions directly concerned in maintaining the life of the individual, inasmuch as it is that through which the animal is enabled to receive aliment and to prepare it for accumulation. The function of digestion includes several minor or subordinate processes. According to Milne-Edwards, the acts of the digestive function may be classed as follows: (1) the prehension of the food, (2) its mastication; (3) its insalivation; (4) its deglutition; (5) its chymification or gastric digestion; (6) its chylification or intestinal digestion; (7) defecation; and (8) the absorption of the chyle. Before examining these acts in detail and the mechanism by which each is effected, it is necessary to have clear conceptions regarding the classification of food, the quantity of food, and other allied subjects, which are discussed in the article *Food*; and it is needful to know the causes of those sensations which we call hunger and thirst, which are, or ought to be, our natural guides regarding the periods for taking food and the quantity to be taken. The immediate cause of hunger cannot be explained; but that it is due to some peculiar condition of the gastric mucous membrane seems probable from the fact that the sensation continues after division of the pneumogastric nerves, from which the stomach mainly derives its nervous fibres, if we correctly interpret the feelings of the animals on which the experiments were made. In extreme hunger the sufferer complains of a sense of sinking, which is referred to the region of the stomach, while general faintness and sometimes considerable pain are present. Hunger, or the want of food which occasions it, may be diminished by rest, sleep, or any cause that retards the general change which is perpetually going on in all the tissues of the body. Tobacco and alcohol tend to limit the disintegration of the tissues and thus to keep off or diminish hunger. When the sensations of extreme hunger are not relieved by food, the body begins to feed upon its own tissues, and the symptoms of starvation (q.v.) begin to manifest themselves. The period at which death occurs from abstinence varies greatly in different animals—young animals always dying sooner than older ones. In man total deprivation usually causes death in about a week; but if a little drink be allowed, life is considerably prolonged.

We may now consider the different acts of which the digestive function is made up.

1. In the act of prehension man and the other vertebrates employ the hands or anterior extremities and mouth, the lips and anterior teeth, and, to a certain extent, the tongue. The prehension of fluids is effected in two ways: sometimes the liquid is poured into the mouth and is allowed to fall down the throat; in other cases, the tongue is used after the fashion of a piston, being drawn within the mouth so as to exhaust the anterior part of that cavity, and fluids are thus forced to enter by atmospheric pressure.

2. Mastication is effected in the mouth by means of the teeth (q.v.), or, in their absence in some animals, by hardened surfaces that perform their functions. The upper jaw is immovable; but the lower jaw, with its teeth, is capable of moving in all directions by means of powerful muscles. It is by the varied move-

ments of the lower teeth against the upper, through the action of these muscles, that the food is broken down or masticated. This operation is very important, since the more completely the food is broken down the more easily will it mix with the saliva and other digestive fluids.

3. Insalivation* is effected by the admixture of the secretions of the three pairs of salivary glands (the parotids, the submaxillaries, and the sublinguals) and of the buccal mucus with the triturated food. (See *GLAND*.) The saliva is a colorless, turbid, viscid, inodorous, and tasteless fluid, which, after standing for some time, deposits a layer of pavement epithelium (see *EPITHELIUM*) and mucus corpuscles. In the normal state its reaction is alkaline, but the degree of alkalinity varies, and is greatest during and after meals. Saliva does not contain more than five or six parts of solid constituents to 995 or 994 parts of water, the most important ingredient being an organic matter termed *ptyalin*, and sulphocyanide of potassium, neither of which substances occurs in any other solid or fluid of the body. The daily quantity of saliva secreted by an adult man is estimated at about 48 ounces, but the activity of the salivary glands is dependent upon various influences and conditions. Thus, movement of the lower jaw, as in masticating, speaking, or singing, increases the secretion as also do acrid and aromatic substances, and dry, hard food; while the use of moist and soft food is accompanied by a scanty secretion. The uses of saliva in reference to digestion are partly mechanical and partly chemical. The moistening of the dry food by the saliva serves the double purpose of adapting it for deglutition and of separating the particles and thus allowing them to be more freely acted on by the other digestive fluids; moreover, from its viscidness, it lubricates the bolus of food and thus facilitates deglutition; and it is probably also subservient to the sense of taste. The great chemical use of the saliva is to convert the amylaceous (or starchy) portion of the food into glucose, or grape sugar, and thus promote its absorption.

4. Deglutition is the act by which the food is transferred from the mouth to the stomach. The pharynx, or cavity into which the mouth leads, takes so slight a part in the digestive process, that we need scarcely allude to any anatomical details connected with it. It is sufficient to observe that between it and the mouth is the pendulous or soft palate, which is a movable muscular partition that separates the two cavities during mastication. As soon, however, as the latter act is accomplished, and the bolus is pressed backward by the tongue, the soft palate is drawn upward and backward, so as to permit the passage of the food into the pharynx. The bolus, or pellet of food, having arrived near the œsophagus, or gullet (which is continuous inferiorly and posteriorly with the pharynx), is driven into it by the action of certain muscles, which almost surround the pharynx and are termed its *constrictor* muscles. All voluntary action ceases as soon as the food is pressed backward by the tongue into the pharynx. It is impossible to recall the pellet, and it is necessarily carried on into the stomach. On receiving the food forced into its upper extremity by the action of the constrictor muscles of the pharynx, the œsophagus is di-

lated (for it usually lies in a collapsed state, with its walls in contact, or nearly so); this contact of the pellet with its mucous membrane causes its muscular walls to contract, and the food is thus driven, by a series of these contractions, into the stomach, thus completing the act of deglutition.

5. Gastric digestion, or chymification, is the next process to be considered. The whole of the alimentary canal (Fig. 1) below the diaphragm (q.v.), or great muscular partition which separates the cavity of the chest from that of the abdomen, or belly, possesses the following characteristics in relation to structure: the stomach, the small intestine, and the large intestine are all lined by mucous membrane, have a muscular coat, consisting of two sets of distinct fibres—viz., circular fibres which surround the tube, or viscus, after the manner of a series of rings, and longitudinal fibres running in the same direction as the intestine itself—and are invested with a serous membrane, the peritoneum (see **SEROUS MEMBRANE**), which at the same time retains the viscera in their proper position and permits their necessary movements.

FIG. 1. HUMAN ALIMENTARY CANAL.

traction of the muscular coat, except when the organ is distended with food. On opening the stomach we may perceive with a lens, even with the naked eye, numerous irregular pits or depressions, irregular in shape and averaging about 1-200th of an inch in diameter (Fig. 2, A). These pits dip into the mucous membrane about one-sixth or one-eighth of its thickness. The rest of the thickness is chiefly made up of minute tubes, running parallel to one another, and vertically to the sur-

face of the stomach (Fig. 2, B). These are the gastric glands which secrete the gastric juice from the blood in the capillaries which abound in the mucous membrane. They pass in twos,

FIG. 2. A, inner surface of the stomach, showing the cells after the mucus has been washed out, magnified 25 diameters. B, stomach tube from the middle of the human stomach, magnified about 150 diameters; a, wall of the tube, lined with large oval, nucleated cells; b, the same cells isolated; c, nucleated cells of columnar epithelium, occupying the upper parts of the tubes; d, blind extremity of the tube.

threes, or fours from the bottom of each pit and usually subdivide into several tubes, which, after running a more or less tortuous course, terminate in blind or closed extremities. These tubes are filled with epithelial cells, whose contents are composed of granules, with which oil globules are often mixed, and each tube is invested with capillaries, which usually run in the direction of its long axis. In the pyloric or duodenal end of the stomach these tubes are considerably wider than those described and differ from them also in other respects; and hence some physiologists believe that while they collectively secrete the gastric juice, one set may secrete the acid fluid and the organic matter termed pepsin, and the other mucus; the free acid and the pepsin are, as we shall shortly see, the two essential constituents of the gastric juice.

When food is introduced into the stomach, three special phenomena are induced: (1) certain movements dependent on the muscular coat; (2) the mucous membrane is altered in appearance; and (3) gastric juice is secreted. Each of these phenomena requires a brief notice.

On killing an animal while the act of digestion is going on, and at once laying open its abdomen, we find that the stomach is in a contracted state, firmly embracing its contents, and with both its orifices so closed as to prevent the escape of the food, this contraction being due to the stimulation of the muscular coat by the food. If we examine the movements of the stomach during digestion, which we can do either by exposing the stomach of a living animal or by sending a magneto-electric current through this organ in an animal just killed, we perceive that in the cardiac portion the movements are extremely slow, the muscular coat apparently contracting on the food and progressively sending it towards the pylorus; while in the pyloric end of the stomach the movements are more energetic and rapid, resembling the peristaltic movements, similar to

those occurring in the intestinal canal. When the transverse constriction has reached the firmly shut pylorus, a relaxation lasting about a minute ensues, followed by a repetition of the circular contractions. The movements which these contractions impress upon the food have been described in the following terms: "The food entering the cardiac end of the stomach, *c*, turns to the left, descends into the splenic extremity, and follows the great curvature towards the pyloric end, *d*. It then returns in the course of the smaller curvature, and makes its appearance again at the cardiac aperture in its descent into the great curvature to perform similar revolutions. These revolutions are effected in from one to three minutes." This account, given by Dr. Beaumont, is based on the observations which he made in the stomach of Alexis Saint-Martin, who had a fistulous opening into the stomach. (See BEAUMONT.) Dr. Brinton, however, adopts a modified view, which is probably the correct one. He supposes that the semifluid food entering at *c* (Fig. 3), the cardiac orifice, goes in the directions marked *a*, partly along the greater and partly along the lesser curvature; and that these two currents of food meet at the closed pylorus, when they are both reflected into the direction *b*, forming a central or axial current, occupying the real axis of the stomach, which unites the two apertures. The mutual interference of these

FIG. 3. Diagram to show the general direction of movement impressed on the semifluid food in the stomach.

aa, the hemispherical or surface current, carrying the semifluid food towards the closed pylorus, where it is deflected into *b*, the central current, which unites the cardiac (*c*) and pyloric (*d*) openings.

currents at their borders causes a uniform admixture of the various substances composing them, while the reflection of the upper and lower currents into one another insures an equal contact of all the mass with the secreting surface of the mucous membrane.

The mucous membrane are mainly the inner surface of the healthy is of a paler pink tint than after the introduction of food, and while in the latter case the reaction of the moisture on the surface is very acid, in the former it is neutral or even alkaline. Dr. Beaumont found (in the case of Alexis Saint-Martin) that, on the introduction of food into the stomach, the vessels of the mucous membrane became more injected, and that its color changed from a pale pink to a deep red. A pure, colorless, and slightly viscid fluid, with a acid reaction, was then observed to trickle down the surface of the membrane and to collect in drops, which trickled down the walls and mixed with the food.

That the gastric juice is capable of exerting a solvent action on food is proved by numerous experiments. It was first ascertained by Réaumur (1752), who obtained some of this fluid by

making animals swallow sponges with a string attached, by which he could withdraw them. He thus showed that alimentary substances out of the body were altered by this fluid in the same manner as they are changed in the stomach, and disproved the favorite theory of that period, which ascribed all the changes which the food underwent in the stomach to a species of trituration. The subject of artificial digestion, or digestion out of the body, has been carefully investigated, and there is now no doubt that the changes which the food undergoes in the stomach are essentially chemical and not mechanical.

Two years before Beaumont's experiments, Dr. Prout had ascertained not only that an acid fluid is secreted by the gastric mucous membrane of rabbits, hares, horses, dogs, etc., during digestion, but that the acid is hydrochloric acid, and it was supposed that the solvent action of the gastric juice was due to this source. But experiments showed that the solvent action is not due simply to the acid of the gastric juice, and that the latter must contain some other ingredients which, either alone or in combination with the acid, can exercise this power. It was then discovered that the addition of a portion of the gastric mucous membrane to water acidified with hydrochloric acid produced a perfect digestive fluid, due attention being paid to the temperature, which should be about 100° F., or about the normal temperature of the interior of the animal body. Later observations showed that we can obtain from the gastric mucous membrane the special ferment on which its digestive power depends, and to this substance the name of *pepsin* has been given. The two essential elements of the gastric juice are, then: (1) a free acid, which in some cases seems to be hydrochloric alone and in others a mixture of hydrochloric and lactic acids; and (2) an organic matter, highly nitrogenous, and allied to the albuminates, called pepsin. The best analysis of human gastric juice is that made by Schmidt of Dorpat, who in 1853 had an opportunity of examining it in the case of an Esthonian peasant, Catharine Kütt, aged 35 years and weighing about 118 pounds, who had a gastric fistula under the left breast, between the cartilages of the ninth and tenth ribs. His analysis is still accepted as authoritative. The introduction of dry peas and a little water into the stomach through the opening (even in the morning, on an empty stomach) occasioned the secretion of from five to seven ounces of a clear limpid fluid with an acid reaction, which, however, was much less strong than Schmidt had observed in previous experiments on the of dogs and sheep, in which he similar fistulæ. The gives the mean of two analyses of juice of Catharine Kütt, with corresponding mean results of the same fluid in the sheep, a purely herbivorous animal, and in the dog, a purely carnivorous animal:

	Human gastric juice	Sheep's gastric juice	Dog's gastric juice
Water	994.40	986.15	971.17
Solid constituents	5.60	13.85	28.83
Pepsin	3.20	4.20	17.51
Hydrochloric acid	0.20	1.56	2.70
Phosphoric acid	2.08	6.00	5.88
Phosphates	0.12	2.09	2.74

The only impurity that could affect these analyses is the saliva that possibly might have been swallowed.

The quantity of the gastric juice secreted in 24 hours was determined by Bidder and Schmidt (*Die Verdauungssäfte, etc.*) in the sheep to be one-eighth, and in the dog one-tenth of the weight of the body. If the latter ratio were true for men, a man of 140 pounds' weight would secrete about 14 pounds of this fluid daily. In the case of Catharine Kütt, the mean daily quantity amounted to no less than 31 pounds, or to more than a fourth part of the weight of her body. On this calculation, a man of 140 pounds weight would daily secrete 37 pounds of gastric juice. Modern physiologists estimate the quantity at from 10 to 20 pints (or pounds).

The uses of this fluid are not only to dissolve, but also to modify, the nitrogenous elements of the food (such as albumen, fibrin, casein, and, in short, all animal food except fat, and the blood-forming portion of vegetable food), converting them into new substances, termed *peptones*, which, although they coincide in their chemical composition and in many of their physical properties with the substances from which they are derived, differ essentially from them in their more ready solubility in water and in various chemical relations. Thus, albumen is converted by the gastric juice into albumen-peptone, fibrin into fibrin-peptone, etc. According to the investigations of Meissner, the albuminates are simultaneously decomposed or broken up into peptones and substances which he terms *parapeptones*, which latter are not further changed by the action of the gastric juice, but are converted into peptones by the action of the pancreatic juice, with which they come in contact in the duodenum.

All observers agree that the gastric juice exerts no apparent action on the non-nitrogenous articles of food, viz., the fats and the carbohydrates (sugar, starch, etc.); as, however, the fats exert a favorable influence on the digestion of nitrogenous matters, it is probable that they undergo some slight, although not appreciable, modification. Gelatin and the gelatinous tissues are, as far as is known, the only nitrogenous articles of food which are not

not dissolve the quantity necessary for the due nutrition of the organism. According to Lehmann, gastric juice can only dissolve one-twentieth of its weight of coagulated albumen, while Schmidt makes the quantity as low as one-forty-fifth. Hence, its gastric juice only suffices for the digestion of half the albuminates necessary for nutrition—a result which is in accordance with the observed fact that a considerable portion of the albuminates enters the duodenum in an undissolved state, and which will be explained when we consider the part which the intestinal juice takes in the digestive process.

The process of gastric digestion is slow. According to Beaumont's researches on Alexis Saint-Martin, the mean time required for the digestion of ordinary animal food, such as butcher's meat, fowl, and game, was from two hours and three-quarters to four hours.

Frerichs and Donders maintain that the absorption of the peptones commences in the stomach; but the view generally adopted is that the albuminates, etc., which are converted into peptones, are for the most part taken up by the lacteals. The rapidity with which aqueous solutions of iodide of potassium, the alkaline carbonates, lactates, citrates, etc., pass into the blood, and thence into the urine, saliva, and other body fluids, shows that the absorption of fluids must take place very shortly after they are swallowed, and there is little doubt that the blood vessels (capillaries) of the stomach constitute the principal channel through which they pass out of the intestinal tract into the blood. As the veins of the stomach, which are formed by the union of these capillaries, contribute to form the portal vein (see CIRCULATION), the absorbed matters pass directly to the liver and probably stimulate it to increased secretion (Fig. 4).

6. We now follow the progress of the semi-fluid mass, known as the *chyme*, from the stomach into the small intestine, and notice the changes which are collectively impressed upon it, known as *chylification*, or intestinal digestion. But a few words are necessary regarding the intestinal mucous membrane, with its various glands, and on the changes which take place in it during digestion.

The mucous membrane of the small intestine resembles that of the stomach in so far as it is of considerable thickness, and consists in a great measure of laterally grouped tubules. Fig. 5 exhibits a section of the mucous membrane of the small intestine in the dog. The tubules, which form the great mass of the middle portion of the section marked *b*, are commonly called the *follicles of Lieberkühn*, although they were first

converted into peptones and parapeptones by the action of the gastric juice.

Although the main object of the gastric juice is to dissolve the albuminates, etc. (e.g., the contents of the egg, flesh, cheese, etc.), it can-

described by Brunner. They are straight, nearly uniform in diameter throughout their entire length, and are parallel to one another, and perpendicular to the inner surface of the small intestine on which they open. The exact nature of their secretion is unknown; but in association with the secretions of other glands, they combine to yield the intestinal juice whose characters and uses will shortly be described.

The projecting bodies marked *a* in the figure are termed the *villi*; they are minute processes of the mucous membrane of the small intestine and obviously serve to increase to a great extent the amount of absorbing mucous membrane. They first appear in the duodenum, where they seem to develop themselves as elongations of the partitions between the cells or pits into which the tubes open. Comparatively scanty in number at first, they become very numerous (covering the whole surface) in the further part of the duodenum and the rest of the small intestines, giving to the mucous membrane a velvet-like or pilous appearance; they finally cease at the ileocaecal valve, which forms the boundary between the small and large intestine. In man they are conical in shape, and measure from $\frac{1}{16}$ to $\frac{1}{8}$ of an inch in length. They vary much in shape and size in the lower mammals and in birds. (In carnivorous animals, as the dog, they are longer and more filiform than in man.)

The structure of a villus (Fig. 6) is some-

A single artery enters its base and, passing up its centre, divides into a capillary plexus, which almost surrounds the villus immediately beneath the mucous membrane. From these arise small veins, which usually pass out of the villus in two, three, or more trunks, and contribute to form the portal vein. See CIRCULATION.

The villus also contains in its interior one or more *lacteals*, which are vessels with club-shaped closed extremities, which absorb the chyle from the intestine. Their milk-white appearance, when they are filled with chyle, suggests the origin of their name. The tissue which occupies the cavity of the villus, in which the lacteals are embedded, and which supports the capillary plexus, is in a great measure made up of nuclei and granules, except at the free extremity, where a vesicular structure, resembling very minute fat globules, is apparent.

The function of the villi is connected with absorption and mainly with the absorption of chyle. They exist only in the small intestine, where the absorption of food chiefly goes on; they are most developed in that part of the intestine where chyle is first formed; they are turgid, enlarged, and opaque during the process of chylification, and small and shrunken in animals that have been kept fasting for some time before death.

In addition to the villi the mucous membrane of the small intestine presents numerous transverse folds, which are termed the *valvulae conniventes*, from their valvular form and from their movements under water resembling the winking motion of the eyelids (Fig. 8). Each fold passes round three-fourths or more of the gut; and in the lower part of the duodenum and in the jejunum (the parts in which they are most fully developed), they are often more than half an inch in depth; farther on they diminish in depth, length, and number, and in the lowest part of the ileum they can scarcely be traced. Their object clearly is to increase the extent of the absorbent mucous membrane.

In addition to Lieberkühn's follicles or tubes, which exist in the whole of the smaller intestine, there are other glandular or secreting structures, embedded in the submucous tissue of certain portions of the intestinal tract. These are: (1) Brunner's glands (q.v.), which occur only in the duodenum; (2) solitary glands, which seem to occur in all parts of the intestines, both small and large; and (3) Peyer's glands, which are usually confined to the ileum.

Brunner's glands are most abundant at the pyloric end of the duodenum. In structure they resemble the pancreas, their ultimate elements being bunches of vesicles, from which minute ducts arise, which coalesce and form larger ducts, through which the secretion is poured into the duodenum. It is believed that they secrete a fluid similar to the pancreatic juice. The *solitary glands* occur in all parts of the intestine, but are perhaps more numerous in the jejunum than elsewhere. Each gland is a simple membranous flask-shaped vesicle, the neck corresponding to the surface of the intestine, while

FIG. 8. Small intestine distended and hardened by alcohol, and laid open to show the *valvulae conniventes*.

FIG. 7. Vertical section of the coats of the small intestine, showing the capillaries and the beginnings of the portal vein. The arteries are not seen, not having been penetrated by the injection which has been thrown into the portal vein. *a*, vessels of the villi; *b*, those of the tubes or follicles of Lieberkühn; *c*, those of the muscular coat.

what complicated. Each villus is provided with an abundant set of capillaries, which doubtless absorb fluid matters, which thus find their way directly from the bowels into the blood (Fig. 7).

the rounded base lies in the submucous tissue. The neck presents no opening, and how the contents, which consist of nuclei and granular particles, are discharged into the intestine is not clearly known. As we never see them larger than a mustard seed, we may presume that on attaining that size they burst. *Peyer's glands* (Fig. 9) are apparently mere aggregations of

FIG. 9. Vertical section through a patch of Peyer's glands in the dog.

a, villi; b, tubes of Lieberkühn; c, submucous tissue, with the glands of Peyer imbedded in it; d, muscular and peritoneal coats; e, apex of one of the glands projecting among the tubes.

solitary glands, forming oval patches in the ileum. These patches vary in size and number, being largest towards the cæcum, where their long diameter sometimes measures 3 or 4 inches, and smallest towards the jejunum, where their number varies from 15 to 20, or even more. Nothing certain is known regarding the uses of these solitary or aggregated glands; but, as they are largest during the digestive process, we must infer that they are in some way connected with that function. Possibly the peculiar odor of the fæces may be due to their secretion. In typhoid or enteric fever and in phthisis these glands become ulcerated, which probably occasions the diarrhœa so common in these diseases.

Brunner's glands are much more developed in the herbivora than in the carnivora; Peyer's on the other hand, are most developed in the latter.

We have endeavored to give the reader some idea of the complicated structure of the mucous and submucous coat of the small intestine; we now proceed to notice the chief uses of the muscular coat of the intestine. This coat consists of two layers of muscular fibres, circular and longitudinal, of which the former lie next to the submucous coat. The peristaltic or vermicular action, by which the substances which enter the duodenum from the stomach are moved onward, is due to this muscular coat. This movement commences in the pyloric third of the stomach, whence successive wavelike movements are propagated through the entire length of the intestinal canal. It is the rapid succession of these alternate contractions and relaxations that impels the intestinal contents onward and occasions those movements which, from their resemblance to the writhings of a worm, have been termed *vermicular*. It is very probable that the rapidity of this movement varies in different individuals—those persons, e.g., whose bowels act twice daily having a more

rapid vermicular motion than those in whom the act of defecation occurs only once in the 24 hours.

We have now to consider the effects produced on the chyme by the different fluids with which it becomes mixed in the small intestine. These fluids are: (1) the bile; (2) the pancreatic juice; and (3) the intestinal juice.

The bile (q.v.) is a faintly alkaline or neutral fluid, containing two essential constituents, one of which is of a resinous nature, while the other is a pigment. The resinous constituent is not precisely identical in all kinds of bile, but it generally consists of a sodium salt whose acid is either glycocholic or taurocholic acid, or of a mixture of these salts. Strecker, to whom we are mainly indebted for our knowledge of the chemistry of the bile, states that in most mammals the resinous constituent merely differs in the varying proportions in which the taurocholates and glycocholates are intermixed, the former usually preponderating. According to Lehmann, the resinous constituent amounts to at least 75 per cent of the solid residue. The bile pigment occurs in the bile of different animals under two forms, viz., as a brown and as a green pigment, the latter probably only differing from the former in being more highly oxidized. There has never been a case in which physiologists have had an opportunity of directly observing the quantity of bile that is secreted by the human subject, and all information on this subject is derived from observations on animals in which the common bile duct (see LIVER) has been tied and a fistulous opening established into the gall bladder. If the same proportion of bile to bodily weight holds good in man as in the dog, a man weighing 140 pounds would secrete daily about 5 pounds of bile. All observers agree that the amount of the biliary secretion varies directly with the quantity of food; and as animals with biliary fistulæ (in whom all the bile escapes externally, instead of making its way into the duodenum) usually have voracious appetites, experiments on this point are easily made. There is great discrepancy of opinion as to how soon after a meal the bile flows most abundantly into the intestine. According to Kölliker and Müller, whose experiments were made on dogs fed only once a day, very little bile is secreted in the first and second hour after a meal, more in the third, fourth, and fifth, the maximum being sometimes attained in the fifth, sometimes not till the eighth hour.

Numerous views have at different times been advanced regarding the functions of this fluid; we shall here notice only those functions which are connected with digestion. One use that has been ascribed to it is to neutralize in the small intestine the acid chyme which emerges from the stomach. But the bile can contribute little or nothing to the neutralization of the free acid, because, in the first place, the bile is very slightly alkaline and often perfectly neutral; and, secondly, because the chyme in the intestine is still acid after the admixture of the bile. Again, the bile has been asserted to possess a special solvent action on the chyme; but none of the ordinary constituents of the latter seem to be essentially changed, even when digested for a long time with fresh bile. Much importance has been attached to the antiseptic action of the bile on the contents of the intestinal canal, in favor of which view it is alleged that

when no bile is poured into the intestine the feces have a putrid odor, as is sometimes observed in patients with jaundice, and as was noticed by Frerichs in animals in which the common bile duct had been tied. Another use assigned to the bile is that it exerts a stimulating action on the intestinal walls and thus acts as a natural purgative; and in support of this view it may be mentioned that jaundice (in which the bile does not flow into the intestine) is often accompanied by extreme constipation, and that purified ox gall, taken either in the form of pill or enema, produces an undoubted purgative action. But the main use of the bile seems to be to promote the digestion of fatty matters; and it accomplishes this end not so much by any solvent chemical action on the fats (which at most is extremely slight) as by a peculiar physical action both on the fats and on the intestinal walls, disintegrating the former and impressing on the latter (by moistening the villi) a peculiar condition which facilitates the absorption of fatty matters. This view is fully confirmed both by direct experiments out of the body and by comparing the relative qualities of fat that are retained in the body and applied to the purposes of life by animals with biliary fistulous openings and by healthy animals.

The pancreatic fluid which is poured into the duodenum at the same spot with the bile (see Fig. 1) is a colorless, clear, somewhat viscid and ropy fluid, devoid of any special odor, and exhibiting a strong alkaline reaction. This fluid, as yielded by different dogs with permanent fistulous openings, varies considerably in chemical composition, the collective solid constituents ranging from 1.5 to 2.3 per cent, the organic matters from 0.9 to 1.6, and the mineral matters from 0.62 to 0.75.

The most abundant and important of the solid constituents is a peculiar substance termed *pancreatin*, or pancreatic diastase or ferment, in combination with soda, to which this fluid owes its principal chemical and properties. Calculating from the quantity of pancreatic juice secreted by dogs of known weight, we may infer that a man weighing 140 pounds secretes daily about 10 ounces of this fluid.

One of the chief uses of the pancreatic juice in relation to digestion is to convert into sugar the amylaceous or starchy matters which have escaped the action of the saliva and have passed unchanged into the duodenum. It possesses this property in a far higher degree than the saliva, and, as might be expected in reference to this use, the pancreas is found to be much more developed in herbivorous than in carnivorous animals. Bernard believes that it is solely by the action of this secretion that the fat is reduced to a condition in which it can be absorbed and digested, i.e., that it is decomposed into glycerin and a fatty acid. (See Table.) This view has, however, not been generally accepted, and it seems probable that, although the change described by Bernard takes place when fat and pancreatic juice are simply mixed together in a test tube, it does not actually take place in the intestine, the acid gastric juice probably acting as an interfering agent. Attempts have been made by Corvisart and Meissner to prove that, like the gastric juice, this fluid can dissolve albuminous matters; but this view cannot be substantiated. Considering the large quantity

of pancreatic fluid which is yielded in 24 hours, Schmidt is of opinion that the function of this fluid is not so much to promote the conversion of starch into sugar as for the purpose of diluting the chyme, and for reconverting the soda (which in the pancreas has been separated from the chlorine of the chloride of sodium and has combined with the pancreatin) into chloride of sodium. He shows, from numerical calculations, that more than half of the chloride of sodium existing in the blood which circulates through the pancreas is broken up into hydrochloric acid and soda, of which the former is separated by the gastric glands, while the latter unites with the pancreatin. Meeting again in the duodenum, the hydrochloric acid and the soda reunite and reform chloride of sodium, which is again absorbed and reenters the circulation. This is perhaps one of the most singular decompositions and reunions occurring in the animal body.

Of the last of the fluids poured into the intestine and coöperating in the digestive process, the *intestinal juice*, we know comparatively little. It is the aggregate secretion of the various glands which we have described as occurring in the walls of the small intestine. It is a colorless, or sometimes yellowish, ropy, viscid fluid, which is invariably alkaline. We are not aware of any special characteristic constituent in it, such as occurs in the other chylipoietic fluids. Its daily quantity is probably 9 or 10 ounces. It seems to unite in itself the leading properties of the pancreatic and gastric juices; i.e., it resembles the former in converting starch into sugar, and the latter in dissolving flesh and other albuminous bodies.

We shall conclude this part of the subject with a few remarks on the chemical composition of the contents of the small intestine. On laying open the gut we usually find a semisolid admixture of imperfectly digested and indigestible substances, and of the constituents of the digestive fluids in a more or less changed condition. The reaction of this mass varies in different parts of the canal and in some measure with the nature of the food. Thus, the contents of the stomach always redden litmus paper, whatever kind of food has been taken; the duodenal contents are also always acid, but in a far less intense degree; in the ileum we meet with only a faint acid reaction, which altogether disappears in the ileum; while in the cæcum, and sometimes in the lower part of the ileum, an alkaline reaction occurs. After a purely animal diet the acid reaction disappears shortly below the duodenum; while, after the sole use of vegetable food, it may sometimes be traced even to the cæcum. As a general rule, the contents of the large intestine are alkaline.

In consequence of the rapid absorption that goes on along the intestinal surface we meet with a comparatively small amount of soluble matters in these contents. Among these soluble matters we often find glucose (or grape sugar), which seems to owe its origin to the metamorphosis of starch, and not to sugar having been present in the food; for after saccharine food has been taken we rarely meet with it in any quantity in the small intestine, its absorption taking place with great rapidity. In the alcoholic extract of these contents we can almost always find evidence of the presence of biliary constituents. In the duodenum, and for a little way beyond it, we find glycocholic and tauro-

cholic acid; descending a little farther, they rapidly diminish, till we find the products of their disintegration; while in the large intestine little more than a trace of these products can be detected. These chemical observations confirm the experiments of Schmidt, which show that nearly half the bile which is poured into the duodenum is decomposed before it reaches the middle of the small intestine.

FIG. 10.

Cæcum inflated, dried, and opened to show the arrangement of the valve.

a, termination of the ileum; b, ascending colon; c, cæcum; d, a transverse constriction projecting into the cæcum; e f, lips of the valve separating the small from the large intestine; g, the vermiform appendix of the cæcum.

testine, see ALIMENTARY SYSTEM; CÆCUM; COLON.) The contents of the large intestine differ very materially from those just considered and constitute the fæces. They are more solid and homogeneous and are often molded into a definite shape by the cells of the colon. The only essential change which the contents undergo in this part of their course is that they increase in solidity, in consequence of the absorption of fluid from them by the mucous membrane. They are propelled forward into the rectum by the vermicular action already described. Here they accumulate, being prevented from escaping by the contraction of the sphincter muscle—a band of strong muscular fibres surrounding and closing the gut at its lower extremity. The act of defecation, or of expulsion of the fæces from the rectum, is effected partly by the muscular fibres of that part of the intestine which are stimulated to contraction by a certain degree of distention, and which are to a certain extent under the influence of the will, and partly by the simultaneous contractions of the abdominal muscles and of the diaphragm, which, by reducing the anteroposterior and transverse diameters of the abdominal cavity, compress the intestinal canal in such a manner as greatly to assist the expulsive action of the rectum. These forces, or some of them (for usually the detrusive action of the muscular fibres of the rectum is sufficient), overcome the passive contraction of the sphincter, and the act of defecation is the result. See FÆCES.

8. The absorption of the chyle forms the completion of the digestive act. The coats of the intestines contain two perfectly distinct sets of vessels—one through which blood circulates, and the other containing a milky or transparent fluid, chyle, or lymph, which after a somewhat circuitous route is poured into the blood. We have already referred to the fact that fluids are absorbed from the stomach and intestine by the

veins and capillaries of the mucous membrane; we now proceed to notice the mode in which the vessels of the second kind—the lacteals—act as absorbing agents. The lacteals are merely a portion of the great lymphatic system of the body, which will be described in a future article. (See LYMPHATIC.) They commence in the villi and possibly also in the intervening mucous membrane; and when an animal is killed while the digestive process is going on, they have, in consequence of their being distended with chyle, the peculiar white or milky appearance which procured for them their name of *vasa lactea*, given by their discoverer, Asellius, in 1622. They pass in great numbers, and in a reticulated arrangement, between the layers of the mesentery, the portion of peritoneum (q.v.) which surrounds the gut and retains it in its proper position. After passing through the mesenteric glands, where their contents seem to become more highly organized, they make their way to the right side of the aorta in the lumbar region, where they finally discharge themselves into an elongated pouch, termed the *receptaculum chyli*. From this pouch the thoracic duct, containing the chyle, passes upward along the vertebral column till it reaches the level of the arch of the aorta, behind which it runs to the left side and discharges its contents into the subclavian vein, close to its origin with the internal jugular, its orifice being protected by two valves. (See CHYLE.) Chyle is in reality incipient blood, which has been formed from the food and has been absorbed from the intestine by the lacteals. We have now traced it to its entrance into the general circulation, and it only remains for it to pass, in conjunction with the venous blood with which it is mixed, through the lungs, in order to be converted into new and perfect arterial blood, fit for the highest processes of organization. Consult: Hare, *Food Factor in Disease* (2 vols., London, 1905); Clarke, *Indigestion* (New York, 1906); Roger, *Alimentation and Digestion* (Paris, 1907); id., *Digestion and Nutrition* (ib., 1910); Taylor, *Digestion and Metabolism* (Philadelphia, 1912).

DIG'GER. A collective term, without ethnic significance, formerly applied to a number of Indian tribes in central California and the adjacent portion of Nevada, probably from their root-digging habit or from their "dugout" dwellings. See SHOSHONEAN STOCK; MAIDU.

DIGGER WASP. See MUD WASP.

DIGGES, digz, SIR DUDLEY (1583-1639). An English diplomatist and jurist, son of Thomas Digges. He was born at Barham, Kent, graduated at Oxford in 1601, and was knighted in 1607. In 1618 he went to Russia and in 1620 to Holland as special Ambassador, but later fell into disfavor through his independent opinions. He was a large shareholder in the East India Company. He was the author of *Rights and Privileges of the Subject* (1642) and *The Compleat Ambassador* (1655). He sat in Parliament for Tewkesbury from 1624 to 1626 and for Kent in 1628.—His son DUDLEY (1613-43), a devoted Royalist, was the author of *The Unlawfulness of Subjects Taking up Arms Against Their Sovereign* (1643).

DIGGES, LEONARD (?-c.1571). An English mathematician, born at Barham, Kent, and educated at University College, Oxford. He became an expert land surveyor and a well-known architect. He was the author of *A Booke Named*

Tectonicon (1556), on measuring land, etc.; *Pantometria: A Geometrical Practise* (1571); and *A Prognostication Everlasting* (1553-56), an astrological work.

DIGGES, THOMAS (?-1595). An English mathematician, the son of Leonard. He was educated at Cambridge and entered Parliament in 1572. He constructed the alterations and fortifications of Dover harbor, served as muster-master-general of the English forces in the Netherlands in 1593-94, and was interested in a search for the dominions of the great "Cam of Cathaia," in the Antarctic seas. He edited his father's *Pantometria* and wrote a great many treatises on science and military engineering.

DIG'GORY. An awkward servant in Goldsmith's *She Stoops to Conquer*.

DIGHTON (dī'tn) **ROCK.** A greenstone boulder near Dighton, Mass., bearing an inscription which has been much discussed by antiquarians. A drawing of the inscription was made by Dr. Danforth in 1680, another by Cotton Mather in 1712, and others in 1730, 1768, 1788, 1790, 1807, and 1812. In 1830 the Rhode Island Historical Society made a careful study of the inscription, which was interpreted by Rafn (*Antiquitates Americane*, Copenhagen, 1845, pp. 357-360) as Norse. The rock was reexamined by Dr. Hoffman for the Bureau of Ethnology in 1886, and the inscription was reproduced and discussed by Mallery in the tenth annual report of the bureau (1888-89, pp. 85, 762, and pl. liv). The inscription is now nearly obliterated. It was probably an Indian petroglyph.

DI GIACOMO, dē jā'kō-mō, **SALVATORE** (1862-). A Neapolitan poet and dramatist, born in Naples. He devoted himself as a scholar to the history of his native city, the popular life of which has found in his poems and plays its most masterly interpretation. His plays 'O voto, *A "San Francisco,"* 'O mese mariano, *Assunta Spina*, and *Quand l'amour meurt*, written in the Neapolitan dialect, and the subjects of which are treated in sonnet form in the *Poesie* and as Italian novelle in *Nella vita*, have enjoyed great vogue in Italy, Germany, and France, and rank among the masterpieces of modern regional literature. His collected works are published (Lanciano, 1910).

DIGIT, dij'it (Lat. *digitus*, finger). A term applied to the 10 symbols of number, 0, 1, 2, . . . 9. Thus, 305 is said to be a number of three digits. Early races were accustomed to indicate numbers by their fingers, and finger reckoning (see **FINGER SYMBOLISM**) played a great part in mediæval computation; hence the name "digit." Originally the term was applied more generally to the nine numbers, 1, 2, . . . 9, and it has also been applied to the characters themselves. The term occurs in a work attributed to Boëthius and was common throughout the Middle Ages, the numbers 10, 20, . . . 90 being called articles, and combinations of articles and digits being called composites. Astronomers use the term "digit" to signify a twelfth part of the diameter of the sun or moon and speak of an eclipse of seven digits, meaning that seven-twelfths of the diameter is covered. See **NUMERALS**.

DIGITALIN, dij'i-tā'lin (from Neo-Lat. *digitalis*). A substance extracted by alcohol from the leaves of the foxglove (*Digitalis purpurea*), growing in Europe. The alcoholic solution is precipitated with water, and the precipitate is

extracted with chloroform, in which digitalin is quite soluble. Digitalin is a crystalline substance sparingly soluble in water and in ether and constitutes one of the active principles of digitalis. The commercial *Homolle's Digitalin*, or *Quévenne's Digitalin*, consists largely of digitalin and is used in France as a substitute for digitalis leaves. The substance known as *Nativelle's Digitalin* has in recent years been recognized as a mixture, consisting principally of *digitonin*, another poisonous glucoside.

DIGITALIS, dij'i-tā'lis (Lat. *digitalis*, pertaining to the finger, from *digitus*, finger; in allusion to the shape of flowers). A genus of plants of the natural order Scrophulariaceæ (Linné), tribe Digitaleæ, natives chiefly of the south of Europe and western and middle Asia, characterized by a five-cleft calyx, campanulate, ventricose corolla, upper lip reflexed, capsule two-celled, flowers in showy racemes. One, the common foxglove (*Digitalis purpurea*), is a native of Great Britain and is very abundant in some parts of the country, its large purple flowers often giving a gay appearance to dry banks and steep hills. The purple-flowered, white-flowered, and yellow-flowered varieties are cultivated in America. *Digitalis purpurea* is much valued in medicine. The leaves of the second year's growth are the parts used. They

FOXGLOVE.

are narcotic and poisonous. The leaves have a disagreeable smell when fresh, and a bitter, nauseous taste, and are violently emetic and cathartic, but, when dried and administered in small doses, they are diuretic, and therefore sometimes useful in dropsy; they are still more

valuable on account of their power over the action of the heart and the circulation of the blood, and are used in some diseases of the heart, in the second stage of pneumonia, in cardiac weakness from collapse, and as the antidote in aconite poisoning. Digitalis owes its efficiency to various alkaloids and other substances, some crystalline, known as digitalin, digitalein, digitoxin, digitonin, and digitin. Digitoxin probably is the actively poisonous agent. Digitalin fulfills all the offices of digitalis in influencing the heart and the circulatory system and is less dangerous. But the drug should never be given except by a physician, who alone can use it safely. In some types of heart disease it is dangerous. In some cases it has a cumulative action resulting in acute poisoning and often in death. The official preparations of digitalis are a tincture, an infusion, a fluid extract, a solid extract, and the powdered leaves.

DIGITIGRADA, dij'i-ti-grā'dā (Neo-Lat. nom. pl., from Lat. *digitus*, finger, toe + *gradi*, to walk). In the zoölogical system of Cuvier, one of the tribes of Carnivora, distinguished by walking on the toes alone, the heel not touching the ground. The word is no longer used as the name of a group, but in the adjective form describes those animals which walk wholly on the toes as opposed to "plantigrade," or walking on the whole sole of the foot. Most mammals are more or less completely digitigrade.

DIGITORIUM, dij'i-tō'ri-ūm. See PIANO-FORTE.

DIGNE, də'ny' (Lat. *Dinia*, Gall. *din*, fort). The capital of the Department of Basses-Alpes, France, at the junction of the Bléonne and the Durance, 60 miles northeast of Marseilles (Map: France, S., L 4). It occupies a picturesque situation at the foot of a mountain slope and is encircled by walls, but its streets are narrow, crooked, and steep. It contains a cathedral, a handsome modern lycée, and a public library. It is the centre of a rich fruit district. Among its chief manufactures are articles of leather, and it has a trade in dried fruits, comfits, marble, honey, wax, woolen and linen cloth, kid skins, etc. In the neighborhood there are several hot saline springs; temperature, 104° F. Of *Dinia*, which is mentioned by Pliny, nothing remains. It embraced Christianity at an early period and has given title to a bishop since the year 340. In 1629 a plague reduced the population from 10,000 to 1500. Pop., 1901, 7238; 1911, 7317. Guichard, *Souvenirs historiques sur la ville de Digne et ses environs* (Digne, 1847).

DIGNITY. In English law, a title of honor or nobility. Such titles are regarded as a species of property, and are classified by Blackstone as incorporeal hereditaments, which, on the death of the owner, pass, like the rest of his real estate, to his heir and not to his personal representative. Like lands, also, dignities are held of the crown, to which they revert by escheat on the failure of heirs, whereupon they may be granted, like escheated lands, to another. The English law recognizes also a species of inferior dignity, as knight, sergeant at law, and esquire, which are not generally inheritable. A superior dignity, or title of nobility, may be employed in legal proceedings without the surname of the bearer, and in early English law the omission of the title or "addition" of a party in a suit was sufficient ground for the abatement of the action. See NOBILITY; TITLES OF HONOR.

DIGONEUTISM. This phenomenon has

been observed in butterflies by Scudder. It is, stated briefly, the result of summer dormancy in the larva or of prolonged life in the pupa. Owing to this prolongation of life in their preparatory stages, all the butterflies of one and the same brood do not appear in the same season, but a portion of the brood flies the next year. Thus, the butterflies belated one year fly and interbreed with their nephews and nieces instead of their brothers and sisters. This is advantageous to the species, since it prevents too close in-and-in breeding.

DIHE'DRAL ANGLE. See ANGLE.

DIJKSTRA, dik'stra, WALING (1821-). A Frisian poet, born in Vrouwen Parish (Province of Friesland). By his poetic works, in which he shows some similarity to Fritz Reuter, he greatly contributed to the extension of the Frisian language and literature. These include: *Doaitse mei de noardsce balke* (3d ed., 1875); *De silveren rinkelbel* (3d ed., 1887); *In doaze fol alde snypsnaren* (in collaboration with Van der Meulen, 2d ed., 1882); *Friske winterjounenocht* (5 vols., 1861-76). Perhaps his greatest work is *Uit Friesland's volksleven van vroeger en later* (Leeuwarden, 1892).

DIJON, də'zhōn' (Lat. *Castrum Divionense*). A town and seat of a bishopric, capital of the Department of Côte d'Or, France, formerly capital of the old Duchy of Burgundy (Map: France, N., L 5). Dijon occupies a delightful situation in a fertile plain on the right bank of the Ouche, where it meets the Luzon and the Canal de Bourgogne, and at the base of the vine-clad hills which produce the famous Burgundy wines, 211 miles southeast of Paris by rail. It is protected by a chain of eight forts. The environs are exceedingly beautiful. Dijon is surrounded by old walls, originally having five gates; the ramparts, planted with trees, have been converted into fine boulevards and promenades. The town is well and regularly built of freestone, and the streets are spacious and clean. Among the public buildings, which are numerous and imposing, the chief are the cathedral of St. Rémi, a massive Gothic structure, dating from the thirteenth century, with a tall wooden spire, more than 300 feet high; the church of Notre Dame, a fine specimen of fourteenth-century Gothic architecture; the church of St. Michel, with a splendid Renaissance front; the theatre, a handsome building having an excellent Corinthian portico; and the palace of the dukes of Burgundy, now used as the town hall. The outside of the palace has been rebuilt, but its internal decorations still survive in their pristine beauty. The museum located in it is rich in monuments of the Middle Ages. Dijon is the seat of a university with three faculties—law, science, and letters—and a library with over 80,000 volumes and 900 manuscripts, and possesses, in addition, a royal college, a theological seminary, a botanic garden, and an academy of art. The manufactures consist of woolen cloth, blankets, hosiery, leather, vinegar, chemical products, cooperage, shoes, flour, machinery, and automobiles; and there are salt refineries, distilleries, and breweries, but the town is mainly dependent on its trade in the wines of Burgundy. It is famous for its mustard and gingerbread. Pop., 1906, 74,113; 1911, 76,847. Dijon dates from Roman times. It came into the possession of the Burgundians in the fifth century and from them passed to the Franks. In the ninth century it was ruled by counts of its

own, under the suzerainty of the bishops of Langres. In the eleventh century it was united to the Duchy of Burgundy, of which it became the capital, and the residence of the dukes, who rebuilt, enlarged, and beautified it. On the death of Charles the Bold (1477) it was annexed to the crown of France by Louis XI. Dijon is the birthplace of Bossuet, the elder Crébillon, Rameau, Rude, and Jouffroy the sculptor. Consult Jos. Garnier, *Chronique de l'abbaye Saint-Bénigne de Dijon* (Dijon, 1876); H. Chabeuf, *Dijon à travers les âges* (ib., 1894).

DIKE, or **DYKE** (AS. *dic*, Icel. *dík*, MHG. *tich*, Ger. *Teich*, pool; probably connected ultimately with Gk. *τείχος*, *teichos*, wall). In geology, a relatively thin body of igneous rock occurring between the separated walls of a fissure. It differs from vein, which it resembles in form, in having its origin by the intrusion and consolidation of molten material, and not by the deposition of minerals from solution. Dikes are usually inclined at considerable angles from the horizontal, and, when the adjacent rock has decayed, they project above the surface like walls of masonry. They vary in width from a few inches to hundreds of feet, the larger dikes sometimes extending a distance of many miles; they reach downward to unknown depths. Proof of their igneous origin is found in the great changes wrought by the strata forming their walls have suffered by the intense heat. Limestone in contact with dikes is changed to crystalline marble; shale is hardened to slate, or by the development of new minerals becomes schist; and bituminous coal assumes the character of anthracite. While of wide occurrence, dikes are especially frequent in regions of crustal folding and volcanic disturbance. They are often found traversing the sides of volcanoes, where they originate during eruptions by fissuring of the cone and filling of the cracks with lava. The consolidation of igneous rocks in the form of dikes develops peculiar features of texture, and this fact has been used by some authorities as the basis of a rock class known as "dike rocks." The sudden chilling of the molten mass produces a fine crystalline intergrowth of the minerals, and dike rocks consequently are usually compact and tough. The basic kinds, such as are commonly called "trap," are much used for crushed stone, for roads and concrete. See GEOLOGY; IGNEOUS ROCKS; VOLCANO.

DIKE. An embankment of earth, most commonly one used to reclaim or protect lands from flooding or formed in land drainage. The term is sometimes applied to low earth dams, generally such as are auxiliary to the main dam, forming an artificial reservoir by closing minor outlets from the natural basin. See DAMS; DRAINAGE; LEVEL.

DIKE (Gk. *Δίκη*). The embodiment of justice in Greek mythology. She is the daughter of Zeus and Themis, and, with her sisters, Eunomia (Order) and Irene (Peace), is reckoned among the Horæ. She is like the Erinyes in that she avenges wrong, but unlike them in that she rewards virtue. Consult Hirzel, *Themis, Dike, und Verwandtes* (Leipzig, 1907), and Harrison, *Themis: A Study of the Social Origins of the Greek Religion* (Cambridge, 1912).

DIKE, *dík*, SAMUEL WARREN (1839-1913). An American Congregational clergyman, prominent as an agitator for reform in the laws of divorce. He was born at Thompson, Conn. He graduated at Williams College in 1863 and at

Andover Theological Seminary in 1866. In 1881 he became corresponding secretary of the Divorce Reform League (now called the National League for the Protection of the Family), which he organized. His writings are mostly in exposition and defense of the principles of the league.

DIKELLOCEPHALUS (Neo-Lat., from Gk. *δικέλλα*, *dikella*, mattock + *κεφαλή*, *kephalē*, head). A genus of Upper Cambrian trilobites of the family Olenidae. The carapace is broad and flat, the head broadly lunate, eyes elongate reniform, glabella short, thorax broad and flat, with nine segments and low axis, and pygidium large, expanded, and flat, with a sharp triangular spine at each posterior lateral corner. The best-known species, *Dikellocephalus minnesotensis*, with a length of 3 to 8 inches, is very common in certain yellow shales of the Upper Cambrian in Wisconsin and Minnesota. A number of other species from the Cambrian and Lower Ordovician of Europe and North America have been incorrectly placed in this genus, which is considered generally as the index fossil of the Upper Cambrian, or Potsdam horizon. See OLENUS; TRILOBITE.

DIKOA, *dë-kô'a*. A fortified town of the old Kingdom of Bornu, in Central Africa, now included in the German Colony of Kamerun. It is situated in a fertile plain about 25 miles south of Lake Chad. Its population is estimated at about 25,000.

DILAPIDATION (Lat. *dilapidatio*, from *dilapidare*, to waste, from Lat. *di-*, apart + *lapidare*, to throw stones, from *lapis*, stone). In the English law, the waste, destruction, or impairment of the church, parsonage, or other ecclesiastical property, or the woods of a benefice or ecclesiastical estate, by the parson or other incumbent. It is dilapidation to permit the buildings to fall into decay for lack of repair as well as to pull them down, but not to waste the glebe or other lands. The obligation of the incumbent of a church living with respect to waste is therefore less extensive, as it is less severely punished, than in the case of an ordinary tenant for life or years. The next incumbent of the living is the person entitled to bring the action, not however against his predecessor who was guilty of the dilapidation, but, after the death of the latter, against his personal representatives. The damages recoverable are the amount necessary to restore the property to a state of good and substantial repair, and the money so recovered must within two years be expended in such restoration and repair. The subject of dilapidations is now mainly regulated by a series of recent statutes, the most important of which are 34 and 35 Vict., c. 43 (1871) and 35 and 36 Vict., c. 96 (1872). Consult Degge, *Parson's Counselor* (7th ed., chap. viii), and Blackstone's *Commentaries on the Laws of England*.

Waste by a tenant for life or years is sometimes described as dilapidation, but is more properly treated under the former title. See WASTE.

DILEMI. The name of a Persian dynasty. See SAMANI and DILEMI.

DILEMMA (Lat. *dilemma*, from Gk. *δίλημμα*, conclusion from two alternatives, *δί-*, *di-*, double + *λήμμα*, *lēmma*, to take). A true dilemma is defined by Whately as "a conditional syllogism with two or more antecedents in the major, and a disjunctive minor." One form of it is represented in the following scheme: If *A* is *B*, *C*, is

D, and if *F* is *G*, *C* is *D*; but either *A* is *B* or *F* is *G*, hence *C* is *D*. There being two mutually exclusive propositions in the minor premise, a person must admit one or the other, and is then caught between the "two horns of the dilemma." See *LOGIC*.

DILETTANTE, dil'ët-tän'të or de'lët-tän'tä (It., pres. part. of *dilettare*, to delight). A term in its original sense synonymous with an *amateur*, or lover of the fine arts, science, or letters. It has, however, come into use as suggesting somewhat the trifle, the dabbler in any or all of those arts which, if seriously pursued, make for civilization and true culture. The dilettante, however, may serve a good purpose, and often does, by interesting himself in the patronage of art and the conservation of objects of art. See *DILETTANTI SOCIETY*.

DILETTANTI SOCIETY. A body of about 60 private gentlemen by whose exertions the study of antique art in England has been largely promoted. The society was founded in 1734 and was in its beginnings simply an amateur club for social intercourse and cultivation of artistic knowledge; but in 1764 it was resolved to fit out an expedition for the purpose of collecting details and drawings of the most remarkable artistic monuments of antiquity. Four distinguished members were sent to Greece and Asia Minor, and after their return two splendid volumes on the architectural antiquities of Ionia were published at the expense of the society (1769-97). Their attention was next turned to sculpture, then at the lowest ebb in England, and a series of engravings of the finest antique statues, bas reliefs, and busts appeared in 1809, with dissertations by Payne Knight. Two more volumes were issued, one in 1817 entitled *The Unedited Antiquities of Attica*, and a second on *Antique Sculpture* in 1835, and other volumes on Ionian antiquities appeared in 1840 and 1881. For further particulars, consult Cust, *History of the Society of Dilettanti*, ed. Colvin (London, 1898; new ed., 1914).

DILIGENCE, dil'i-jens, *Fr. pron.* de'lë'zhäns' (Fr., from Lat. *diligentia*, attentiveness, from *diligere*, to love, choose, from *di-*, apart + *legere*, to choose). A name used in France and Russia for a public conveyance resembling a stagecoach. It was a huge, strong-built vehicle, with 4 broad wheels, weighing with its load about 5 tons, and was drawn by 4 stout horses, at the rate of about 6 miles an hour. It consisted of 3 chief compartments: the front, called the *coupé*, for 3 persons; the second, called the *intérieur*, for 6 persons; and, lastly, the *rotonde*, entered from behind, for 6 persons. Aloft, in front, was the *banquette*, where the *conducteur* was seated; and behind this, underneath a thick leather covering, passengers were sometimes huddled among luggage and goods, with little regard to their comfort. All the places in the body of the vehicle were numbered and assigned in the order of booking. Usually an effort was made to be booked early, in order to secure corner seats. In booking it was customary to pay only a portion of the fare, called *arrhes* ('earnest money'), the remainder being paid at the end of the journey. The driver being concerned only with the horses, the entire management of the vehicle, including the charge of the drag or break, devolved on the *conducteur*, a personage dressed in a blue cloth jacket and cap, and having a badge on his breast indicative of his dignity. In France the diligence system

has become obsolete with the development of railways, but in Russia this curious vehicle may still be seen plying between towns unconnected by rail or water.

DILKE, dilk, CHARLES WENTWORTH (1789-1864). An English critic and antiquary. He graduated at Cambridge, was for many years an official in the navy pay office, and from 1830 to 1846 edited the *Athenæum*, of which he had in the former year become proprietor. He edited *Old English Plays* (6 vols., 1814-16). In 1846-49 he managed the *Daily News*. He was a friend of Keats, Hood, Leigh Hunt, Barry Cornwall, and Lamb, and between 1847 and 1864 wrote for the *Athenæum* a number of valuable literary essays, collected as *Papers of a Critic* (2 vols., 1875). He gathered biographical data regarding Pope and other English authors, and from time to time presented his findings in *Notes and Queries* and elsewhere.

DILKE, SIR CHARLES WENTWORTH (1810-69). An English politician, born in London and educated at Cambridge. He was a zealous promoter of the great International Exhibition of 1851 and was one of the English commissioners of the New York Industrial Exhibition of 1853. He was also one of the five royal commissioners for the Exhibition of 1862 and shortly afterward was made a baronet. In 1865 he was a member of Parliament, and in 1869 representative of Finsbury at the St. Petersburg Horticultural Exhibition. A collection of his writings, *Papers of a Critic* (2 vols., 1875), contains a biographical sketch by his son.

DILKE, SIR CHARLES WENTWORTH (1843-1911). An English politician and author, born at Chelsea, the grandson of Charles Wentworth Dilke (q.v.). He graduated at Cambridge in 1866, traveled extensively in the United States, Canada, and the British countries in the East, and embodied his observations in *Greater Britain: A Record of Travel in English-Speaking Countries during 1866-67* (1868). He represented Chelsea in Parliament from 1868 to 1886, was Undersecretary of State for Foreign Affairs from 1880 to 1882, and was President of the Local Government Board from 1882 to 1885. Always a Radical, he was fiercely attacked in the seventies for his avowed republicanism. Among the reform measures carried by him was the one giving the municipal franchise for women. In 1881 he was chairman of the Royal Commission on the Housing of the Working Classes. In 1886 a Mr. Crawford secured a divorce from his wife, and Sir Charles Dilke as correspondent. In the trial, he was elected member of Parliament for Chelsea, it being understood that he would resign if the verdict went against him. He retired from public life, but in 1892 took a seat in Parliament for the Forest of Dean, with much of his old prestige as a leader but remaining out of office. He succeeded his father and grandfather as proprietor of the *Athenæum* and became the owner of *Notes and Queries*. Besides the work already mentioned, he published a clever political satire called *The Fall of Prince Florestan of Morocco* (1874); *The Present Position of European Politics* (1887); *Problems of Greater Britain* (1890); *Imperial Defence* (1892; with Spenser Wilkinson), and *The British Empire* (1898); edited his grandfather's *Papers of a Critic*; and prefixed a memoir of his wife (see the next title) to *The Book of the Spiritual Life* (1905).

DILKE, LADY EMILIA FRANCES STRONG (1840-1904). An English author, born at Ilfracombe. She became a contributor to the *Saturday Review* in 1864 and subsequently was for many years fine-art critic of the *Academy*. In addition to numerous articles in periodicals, she published: *The Renaissance of Art in France* (1879); a biography of Lord Leighton (1881, in Dumas's "Modern Artists Series"); *Art in the Modern State* (1884); *French Painters of the Eighteenth Century* (1899); *French Architects and Sculptors of the Eighteenth Century* (1900); *French Engravers and Draftsmen of the XVIIIth Century* (1902); *Book of the Spiritual Life*, with memoir of the author by Sir C. W. Dilke (1905).

DILL (AS. *dile*, OHG. *tilli*, Ger. *Dill*, from Dutch *dille*; origin obscure), *Anethum*. A genus of plants of the family Umbelliferae, having compound umbels without general or partial involucre. *Dill* (*Anethum graveolens*) is an annual or biennial plant, which grows wild in grain fields in the East and in the countries around the Mediterranean. It is quite hardy in Great Britain and is cultivated and growing wild to some extent in the United States. It has from a very early period been in general cultivation as an aromatic stimulant and carminative. It has a stem 1 to 4 feet high, bearing at top a flat umbel of 10 to 30 rays; the leaves much divided, and the final segments threadlike. It has strong, peculiar aromatic smell and taste; the leaves and fruits are extensively used for flavoring pickles, sauces, etc. The fruit (dillseed) is used in medicine, chiefly for relief of flatulence in infants, and is administered in the form of dill water in the preparation of which oil of dill is employed—a pale-yellow essential oil, on which the properties of the plant depend, and which is obtained by distillation. Sowa dill (*Anethum sowa*), now considered as identical with the preceding, is a native of Bengal, and is much cultivated in the East Indies for its fruit, which is variously used in medicine and flavoring. It is a common ingredient in curries. The plant much resembles common dill, but its flavor is stronger.

DILL, LUDWIG (1848-). A German landscape and marine painter. He was born at Gernsbach (Baden) and studied engineering and architecture before taking up painting at the Munich Academy under Raab, Seitz, and Piloty. He was first influenced by Lier and the Barbizon painters, and afterward, during a sojourn in Italy, by Baisch. The works of his earlier period, largely marines and fishing scenes painted on the island of Chioggia, are characterized by great breadth of handling. A good example is "Sirocco" (Mannheim Gallery). After a visit to Holland he returned to Munich and took up his residence at Dachau, where he continued to spend part of each year. He devoted himself to pure landscape and under the influence of the Scottish school gradually developed greater realism and subdued yet luminous effects of color. His latest works are expressions of mood rather than direct interpretations of nature. Among the best are: "Meadows" (Pittsburgh Gallery); "Sacred Grove" (Munich); "A Brook in the Moor" (Dresden); "A Corner of the Giudecca" (1910); "A Canal" (Mühlhausen); "November" (Munich). One of the founders of the *Verein für Kunst und Kunstgewerbe* organization, he

was its president from 1894 to 1899, and in 1897 he founded, with Hölzel and Langhammer, the so-called "Dachau Group." He was one of the judges at the Chicago and Paris expositions and became a professor at the Karlsruhe Academy. Consult Rössler, *Neu-Dachau* (Bielefeld, 1905).

DILL, SIR SAMUEL (1844-). A British educator and historian of Roman society. He was educated at Queen's College, Belfast, and at Lincoln College, Oxford, where he was lecturer in 1869. He was fellow, dean, and tutor of Corpus Christi in 1869-77, head master of Manchester Grammar School in 1877-88, after 1889 Commissioner of Intermediate Education for Ireland, and in 1913 chairman of the vice-regal committee on primary education. His *Roman Society in the Last Century of the Western Empire* (1898) and *Roman Society from Nero to Marcus Aurelius* (1905) treat more than capably a topic of which there is hardly any other systematic summary, and carry on Friedländer's *Sittengeschichte Roms*.

DILLENBURG, dil'en-burg. The capital of the circle of Dill, Hesse-Nassau, Prussia, picturesquely situated on the Dill, 21 miles southwest of Marburg (Map: German Empire, C 3). The Wilhelmsturm, a tower 130 feet high, now occupies the site of the ancient Dillenburg Castle, in which was born William of Orange, liberator of the Netherlands, in 1533. Iron mining is the chief industry; leather tanning is also carried on. A mining school is one of the educational institutions. Pop., 1900, 4470; 1910, 5371.

DILLENIUS, or DILLEN, JOHANN JAKOB (1687-1747). A German-English botanist. He was born at Darmstadt, Germany. After holding a professorship at the University of Giessen he went to England (1721) and was in charge of the celebrated Sherard Botanical Gardens at Eltham, Kent, for several years. In 1734 he was appointed Sherardian professor of botany at Oxford, where he remained until his death. His work on mosses, entitled *Historia Muscorum in qua circiter Sexcentæ Species Veteres et Novæ ad sua Genera Relatæ Describuntur* (1741; reprinted, 1811), was long accepted as the standard authority on the subject. Consult Schilling, *Johann Jakob Dillenius* (Hamburg, 1888).

DILLER, JOSEPH SILAS (1850-). An American geologist, born at Plainfield, Pa. He studied at Harvard University and at Heidelberg, Germany. From 1881 to 1883 he served as geologist to the Assos expedition. In 1883 he was appointed to the staff of the United States Geological Survey. He wrote numerous papers and monographs, chiefly relating to the Pacific coast region, including: *Geology of the Lassen Peak District* (1889); *The Coos Bay Coal Field* (1899); *Geology and Petrography of Crater Lake National Park, Oregon* (1902), etc. etc. in the latter work with H. B. Patton.

DILLINGEN, dil'ling-en. A town of Bavaria, on the Danube, 24 miles northwest of Augsburg. Its principal buildings are the palace, royal gymnasium and Latin school, a library of 75,000 volumes, a Capuchin monastery, a Franciscan nunnery, and a deaf and dumb asylum. The University, which was founded in 1544 and became one of the chief seats of the Jesuits, was suppressed in 1804 and is now a royal lyceum. There are manufactures of cutlery, cloth, paper, and twine, but the prin-

cipal pursuits are . . . Pop., 1890, 5775; 1900, 6077; . . . In the Middle Ages the town was the seat of the counts of Dillingen, and from 1286 until 1803, when it came into the possession of Bavaria, it belonged to and was the residence of the bishops of Augsburg.

DILLINGHAM, WILLIAM PAUL (1843-). An American lawyer and Republican politician, born at Waterbury, Vt., son of Paul . . . Governor of the State in 1865-67. He was admitted to the bar in 1867, was Secretary of Civil and Military Affairs of Vermont in 1866 and 1874-76, a member of the Lower House of the Vermont Legislature in 1876 and 1884, and of the Senate in 1878 and 1880. In 1888-90 he was Governor of the State and in 1900 was elected to the United States Senate to take the seat of Justin S. Morrill (q.v.) and was reelected for the terms 1903-09 and 1909-15. In 1907 he was chairman of the United States Immigration Commission.

DILLMANN, dīl'mān, CHRISTIAN FRIEDRICH AUGUST (1823-94). A German Orientalist and theologian. He was born at Illingen, Württemberg, and educated at Tübingen, where in 1852 he became lecturer. In 1854 he became professor of Oriental languages at Kiel, and in 1864 professor of Old Testament exegesis at Giessen. He became professor of Old Testament exegesis at the University of Berlin in 1869, and in 1877 a member of the Royal Academy of Sciences. He is noted for researches in the Ethiopic language, of which he published a . . . (1857; revised by Bezold, 1899), a . . . (1865), and parts of the Ethiopic Bible (1853-94). Contrary to the views of most modern critics, he argued that the Priestly Codex was pre-Deuteronomic. He wrote commentaries on Job (1869; 4th ed., 1891); Exodus and Leviticus (1880; 3d ed., 1897); Genesis (1875; 6th ed., 1892; English, 1897); Numbers, Deuteronomy and Joshua (1886); Isaiah (1890); and published: *Ursprung der alttestamentlichen Religion* (1865); *Die Propheten nach ihrer politischen Wirksamkeit* (1868) and, edited by Kittel, *Vorlesungen über Theologie des Alten Testament* (1895). Consult Baudissin's sketch (Leipzig, 1895).

DILLON, JOHN (1851-). An Irish politician and agitator. He was born in Dublin, the son of John Blake Dillon (1816-66), a prominent member of the Young Ireland party. Dillon was educated at the Catholic University of Dublin and the Royal College of Surgeons of Ireland. He early identified himself with the Parnellite movement and in 1880 was returned for Tipperary. In Parliament he soon became prominent for the violence of his language, while his connection with the "Plan of Campaign," inciting the Irish tenants to lawlessness, led to his imprisonment in 1888 and 1891. From 1883 to 1885 he was out of Parliament because of ill health; but in 1885 he was elected for East Mayo, which he represented thereafter. He succeeded Justin McCarthy as chairman of the Irish Nationalist party in 1896 and held this position until 1899. He visited the United States on several occasions between 1882 and 1894.

DILLON, JOHN FORREST (1831-1914). An American lawyer. He was born . . . Co., N. Y., and early in life . . . where he successively became State prosecuting attorney (1852-58), judge of the Supreme

Court of Iowa (1863-69), and judge of the United States Circuit Court, Eighth Judicial District (1869-79). From 1879 to 1882 he was professor of real estate and equity jurisprudence at Columbia Law School in New York City. He became prominently known as a railroad lawyer and was associated as general or consulting counsel with the Manhattan Elevated and Union Pacific railroad companies and with the Western Union Telegraph Company. His works include: *Municipal Corporations* (1872); *Removal of Causes from State to Federal Courts* (1877); *Laws and Jurisprudence of England and America* (1894); *John Marshall* (3 vols., 1903); *Commentaries on the Law of Municipal Corporations* (revised and enlarged, 1911).

DILLON, WENTWORTH. See ROSCOMMON, EARL OF.

DILOLO, dē-lō'lō, LAKE. A small lake in Angola, near the southern boundary of Belgian Congo, situated in lat. 11° 30' S., long. 22° 30' E. Its altitude is about 4700 feet. It lies on the watershed between the river systems of the Congo and the Zambezi, with both of which it may be connected. Lake Dilolo was discovered by Livingstone in the beginning of 1854. It abounds in hippopotamuses and fish.

DILTHEY, dēl'ti, WILHELM (1834-1911). A German philosopher. He was born at Biebrich and was educated at . . . and Berlin. He occupied the chairs . . . at Basel in 1866, Kiel in 1868, Breslau in 1871, and Berlin in 1882. In *Einleitung in die Geisteswissenschaften* (1883) he endeavors to furnish a rational basis for the sociological and historical sciences by eliminating metaphysics and substituting psychology as a primary factor. He wrote also *Das Erlebnis und die Dichtung* (1906).

DILUENTS (from Lat. *diluere*, to wash away, from *di-*, apart + *luere*, to wash). Medicines whose purpose is to dilute the blood and increase the quantity of the excretions generally. The simplest and best of diluents is pure water; but all watery fluids, such as lemonade, soda water, beer, infusions, tea, etc., may be regarded as . . . this designation.

DILUVIUM (Lat. flood, from *diluere*, to wash away). A name formerly given by geologists to those strata which they believed to have been formed by the deluge and more particularly to the bowlder clay. When the adjective—diluvial—is employed by modern writers, it is to characterize those accumulations of gravel or angular stones formed during the Pleistocene period. The term is little used by modern writers, except perhaps in Germany.

DIMAN, JEREMIAH LEWIS, D.D. (1831-81). An American Congregational . . . He was born in Bristol, R. I., graduated from Brown University in 1851 and from Andover Theological Seminary in 1856 and died in Providence, where he had been professor of history and political economy in Brown University since 1864. He was an able preacher and orator and is remembered by his posthumous publications, *The Theistic Argument* (1881) and *Orations and Essays* (1881). For his biography, consult Caroline Hazard (Boston, 1887).

DIMANCHE, dē'mānsh', MONSIEUR. A merchant in Molière's *Don Juan*, who unsuccessfully attempts to collect his bills. The term is in use in France as the synonym for a dun.

DIME (OF. *disme*, Lat. *decimus*, tenth, from *decem*, ten). In the United States, a silver coin

whose value is 10 cents, i.e., one-tenth of a dollar. Hence such phrases as "dime novels" and "dime museums."

DIMENSION (Lat. *dimensio*, from *dimetire*, to measure off, from *di-*, apart + *metiri*, to measure). In geometry, a line, whether straight or curved, has one dimension, viz., length; a plane surface has two, length and breadth; and a solid has three, length, breadth, and thickness. In algebra the term "dimension" is applied in much the same sense as "degree," to express the number of literal factors contained in a product. Thus, x^2 , xy , $2ab$ are said to be of two dimensions; x^3 , x^2y , $\frac{a^2bc}{a}$, of three; and so on. In

physical measurements the power to which the unit (q.v.) of measure enters determines the dimension of the expression. The form of any material body may be described in terms of at least three dimensions; hence the space in which these forms or figures exist is usually regarded as tri-dimensional. However, the possibility of the existence of a space having more than three dimensions has long been recognized. Such an hypothesis is of service to the mathematician in explaining analytic phenomena. Since points, lines, and surfaces, in general, generate by their motion lines, surfaces, and solids, respectively, it may be inferred that some movement of a figure of three dimensions can generate a figure of four dimensions. Analytically it is only necessary to imagine four parameters or coördinates belonging to each point of four-dimensional space, or five in five-dimensional space, and so on, in order to develop a system of analysis as logical in itself as that of only three dimensions. Figures to represent some features of four-dimensional bodies have been imagined. (See CHASLES; CHARACTERISTIC; GEOMETRY.) On the question of a fourth dimension, consult Schubert, *Mathematical Essays* (Chicago, 1898), and Manning, *The Fourth Dimension Simply Explained* (New York, 1910). A popular discussion may be found in Abbott, *Flatland* (Boston, 1891); Schofield, *Another World* (London, 1890); Hinton, *New Era of Thought* (ib., 1886).

DIMENSIONS. All physical quantities, such as force, energy, electric intensity, magnetic poles, etc., admit of mathematical expression in terms of the elementary ideas of physics. Thus, all mechanical quantities can be expressed in terms of mass, length, and duration of time. All electrical and magnetic quantities can be expressed in terms of mass, length, duration of time, and the "inductivity" of matter for electric or magnetic forces. (See ELECTRICITY.) Thus, velocity is defined as the limiting value of Δx to Δt where Δx is the distance traversed in the time Δt ; consequently velocity involves the idea of a number of units of length divided by a number of time units: its "dimensions" are said to be $\frac{L}{T}$ or LT^{-1} . If, therefore, on any system

of units, e.g., the C. G. S. system (q.v.), the numerical value of a certain velocity is V , its value on a system of units in which the unit of length is 10 times as . . . the former system would be $V/10$. . . acceleration, or the rate of change of . . . with reference

to the time, has the dimensions $\left(\frac{L}{T}\right) \div T$, or LT^{-2} . Force is measured by the product of acceleration and mass; its dimensions are therefore LTM^{-2} .

In the following table are given the dimensions of various mechanical quantities:

Acceleration	LT^{-2}
Force	MLT^{-2}
Pressure	$ML^{-1}T^{-2}$
Work	ML^2T^{-2}
Energy }	
Moment of force	ML^2T^{-2}

If K and μ are written for the dimensions of electric and magnetic inductivity, the dimensions of electric and magnetic quantities have the following values. In the first column are given the electrostatic system of units; in the second, the electromagnetic. (See ELECTRICITY.)

Electric quantity . . .	$L^{\frac{1}{2}}M^{\frac{1}{2}}T^{-1}K^{\frac{1}{2}}$ or $L^{\frac{1}{2}}M^{\frac{1}{2}}\mu^{-\frac{1}{2}}$
Electric current . . .	$L^{\frac{1}{2}}M^{\frac{1}{2}}T^{-2}K^{\frac{1}{2}}$ or $L^{\frac{1}{2}}M^{\frac{1}{2}}T^{-1}\mu^{\frac{1}{2}}$
Magnetic pole	$L^{\frac{3}{2}}M^{\frac{1}{2}}T^{-1}\mu^{\frac{1}{2}}$
Electric resistance	$LT^{-1}\mu$
Electromotive force . . .	$L^{\frac{1}{2}}M^{\frac{1}{2}}T^{-1}K^{-\frac{1}{2}}$ or $L^{\frac{1}{2}}M^{\frac{1}{2}}T^{-2}\mu^{\frac{1}{2}}$
Electric capacity . . .	LK $L^{-1}T^2\mu^{-1}$

The dimensions of any one physical quantity, however expressed, must be identical; and therefore, choosing electric current

$$L^{\frac{1}{2}}M^{\frac{1}{2}}T^{-2}K^{\frac{1}{2}} = L^{\frac{1}{2}}M^{\frac{1}{2}}T^{-2}\mu^{-\frac{1}{2}} \text{ or } LT^{-1} = \mu^{-\frac{1}{2}}K^{-\frac{1}{2}}. \text{ Hence } \mu K = L^{-\frac{1}{2}}T^{\frac{1}{2}}.$$

This means that, although the dimensions of neither electrical nor magnetic inductivity are known in terms of length, mass, or time, the product of the two has the dimensions $L^{-\frac{1}{2}}T^{\frac{1}{2}}$, i.e., the same dimensions as the square root of the reciprocal of a velocity.

It should be noted that work and moment of force have the same dimensions; but there is a difference in this respect—in work the element of distance is in the direction of the force, while in moment of force the element of distance is at right angles to the direction of the force. This might be indicated by calling X and Y the dimensions of length in directions at right angles to each other; in which case force has the dimensions MXT^{-2} ; work, MX^2T^{-2} ; moment of force, $MYXT^{-2}$.

In any equation connecting physical quantities it is evident that the dimensions of the quantities on the two sides of the equation must be identical; for a mass cannot equal a length, etc. This fact is often useful either in verifying general conclusions or in . . . the connection between various The subject of dimensions is thoroughly treated in Daniel's *Text-Book of the Principles of Physics* (London, 1894); Maxwell, *Heat* (ib., 1891); Everett, *The C. G. S. System* (ib., 1902).

DIMETHYL KETONE. See ACETONE.

DIMIDIATION (Lat. *dimidiatio*, a halving, from *dimidiare*, to halve, from *dimidius*, half, from *di-*, apart + *medius*, middle). In heraldry, the marshaling of arms (q.v.) followed chiefly before quartering and impaling came into use and retained to some extent in continental heraldry. It consists in cutting two coats of arms in half by a vertical line and uniting the dexter half of the one to the sinister half of the other.

DIMINUENDO (It., diminishing). A term in music, meaning "to diminish in loudness." Diminuendo can be applied to a single note,

when it is a long note, as well as to a passage of many notes; but the diminuendo on a single note can be executed only on wind instruments or on stringed instruments played with a bow. Diminuendo is so nearly of the same meaning as decrescendo that it is frequently marked with the same sign, thus: 

DIMINUTION (Lat. *diminutio*, *deminutio*, from *deminuere*, to lessen, from *de*, down + *minuere*, to make small, from *minor*, less). In music, the repetition of a theme in such a manner that each note of the original theme is reduced to one-half or one-quarter of its original value. Diminution occurs most frequently in the stretta of the  in the free style of writing.  of intervals, see INTERVAL.

DIMINUTIONS. A word used in heraldry indiscriminately for differences, marks of cadency, and brisures.

DIMINUTIVE (Fr. *diminutif*, ML. *diminutivus*, from Lat. *diminutivus*, diminutive, from *diminutus*, p.p. of *diminuere*, to lessen). A form of words, chiefly of substantives, in which the primitive notion has become lessened or diminished, as *hillock* = a little hill. With littleness is associated the idea of neatness and also of needing protection; hence diminutives are used as terms of endearment; sometimes they imply contempt. There is perhaps no language without diminutives, and the most common method of formation is by the addition of a syllable. The commonest of the English diminutive affixes are *ock*, *kin*, *el*, or *le*, which are of Germanic origin, and *et* or *let*, of classical origin; as in *bullock*, *lambkin*, *kernel* (little corn), *lancet*. The termination *ling*, or rather *ing*, was ori-

... occur in proper names; *Perkin* is the diminutive of *Peter*, *Jenkin* of *John*. These have settled down into permanent and distinct names; but in the language of fondness and familiarity *Charles* becomes *Charley*; *John*, *Johnny*; etc. In Lowland Scotch this form of diminutive is not confined to proper names, but is applied to every object, animate or inanimate—*laddie*, *horsie*, *wifie*, *frie*. Sometimes one diminutive affix is joined to another, as *lassock*, *lassockie*; and in expressions like “*A wee, wee but horsilie*,” the diminution is carried to the fifth degree. It is principally in the mouths of the people and in friendly familiarity that these diminutive forms are most common. Italian is remarkable in this respect, especially the Tuscan dialect. *Casa*, house, becomes *casarella*, little house, and *casarellina*, pretty little house; from *fratello*, brother, which is itself a diminutive of the Latin *frater*, children, it is said, may be heard forming such fond names as *fratellinucciuettinetto*, in which the diminution may be said to be carried to the sixth degree. The principal diminutive suffixes in Italian are those in *-ino*, *-etto*, *-cello*, *-cino*, *-icino*, which indicate both smallness and prettiness and oftentimes endearment; *-erello*, *-uccio*, *-ello*, used to express affection or contempt; and *-accio*, *-astro*, *-icciuolo*, which convey an idea of badness, contempt, weakness, and the like.

Spanish is peculiarly wealthy in the number and variety of its diminutive endings, most of which contain some special shade of caressing or disparaging signification. Those most commonly used are the suffixes *-ito*, *-illo*, *-uelo*, *-cito*, *-cillo*, *-zuelo*, *-ecito*, *-ecillo*, *-ezuelo*, *-ico*, *-cico*, *-ecico*, *-ete*, *-cete*, *-ejo*, and *-ín*. They are added,

often indiscriminately, to nouns and adjectives. The affection of the Germans expresses itself largely in this form; *vater*, father, becomes *vaterchen*, dear father; and even the pronoun *du*, thou, is made into *duchen* and *duli*. Some of the Low German dialects are even richer than German in diminutives.

Diminutives are not confined to nouns; *whitish* is the diminutive of the adjective *white*; and *tipple*, *scribble*, *dandle*, are examples of diminutive verbs. Opposed to diminutives are augmentatives, which abound in the Romance languages, especially in Italian and Spanish, and express not only largeness, but coarseness and vulgarity. Thus, in Italian, *-one* indicates size, whereas *-otto* gives an idea of strength. The suffixes *-ón* and *-azo* in Spanish indicate size, the latter being usually associated with grotesqueness; *-ote* is either augmentative or depreciative, whereas *-acho*, *-ucho*, and *-ajo* express disdain or contempt. We find also in Spanish combinations of both augmentative and diminutive endings in the same word. Thus, *hombroazonazo* means a 'big, awkward man,' *picaroncillo*, 'a small man who is a great rogue.'

DIMITRI RUDIN, dé'mě'trě' rōō'dēn'. A novel by Turgenieff (1855).

DIMITTY (ML. *dimitum*, Gk. *διμυρος*, *dimitos*, dimity, from *δι*-, *di*-, double + *μυρος*, *mitos*, thread). The name originally applied to a stout figured cotton fabric, first made in Spain and used chiefly for bed hangings. Dimities and fustians were made by the Massachusetts colonists as early as 1643. The figure or stripe is raised on one side and depressed on the other, so that the two faces present reversed patterns. It is commonly white or of a single color; but variegated dimities are made, the pattern and the ground being of different colors. The name is also applied to a fine cotton fabric for dresses, which sometimes resembles the coarser kind in that the figure or stripe is reversible, being raised on one side where it is depressed on the other.

DIMMESDALE, dīmz'dāl, ARTHUR. A powerfully drawn character in Hawthorne's *Scarlet Letter*. He is a clergyman of intense sensitiveness, living a blameless life, but tormented by the consciousness of his concealed sin formerly committed with Hester Prynne.

DIMOCK, dim'ok, or **DYMOKE**. A Lincolnshire family which has held the feudal title "Champion of England" since 1377. See CHAMPION.

DIMORPHISM. 1. In plants. See LEAF;
POLLINATION. 2. In animals. See POLYMOR-

DIMORPHODON (Neo-Lat., from Gk. διμορφος, *dimorphos*, two-formed + δδών, *odōn*, Ionic for δδός, *odós*, tooth). The oldest-known genus of the Ornithosauria, allied to the pterodactyl and rhamphorhynchus, and found fossil in the Lower Liassic rocks near Lyme Regis, in the south of England. The head is large, and the jaws are armed with two kinds of teeth—those in the anterior half of the jaws are large, irregularly arranged, and serrated, while those in the posterior portions of the jaws are small and closely set. Both pairs of legs are long and slender, and the fourth fingers of the fore limbs are greatly elongated, to furnish support for the membranous wings. *Dimorphodon* is the earliest-known vertebrate animal that possessed the power of flight, and it antedated the earliest-known bird, *Archæopteryx*, of the Ki-

from the Lower or Upper Jurassic, by almost the entire period of the Jurassic period. See ORNITHOSAURIA; PTERODACTYL.

DIMORPHOUS. See ISOMORPHISM.

DIMSDALE, THOMAS (1712-1800). An English physician,bert Dimsdale, one of the companyPenn on his first voyage to America, in 1682. He was born at Theyden-Gernon, was educated at St. Thomas's Hospital, and practiced medicine at Hertford. His work upon inoculation, entitled *The Present Method of Inoculation for the Smallpox*, was first published in 1767 and was subsequently frequently reprinted. His fame as an inoculator for the smallpox spread rapidly, and in 1768 he was invited to St. Petersburg to inoculate the Empress Catharine and several of her family. For this service he received a sum equivalent to \$50,000 and an annuity, besides other valuable gifts. In 1784 he made another voyage to the Continent and visited the courts of St. Petersburg, Vienna, and Berlin. His medical works include: *Thoughts on General and Partial Inoculation* (1776); *Observations on the Plan of a Dispensary and General Inoculation* (1780); *Tracts on Inoculation* (1768, 1781).

DIMYARIA. See LAMELLIBRANCHIATA.

DINAH. The daughter of Jacob and Leah. According to Gen. xxxiv, she was violated by Shechem, the son of Hamor, a Hivite ruler. An alliance with the sons of Jacob was proposed and accepted on condition that Shechem's people be circumcised. Before their wounds were healed, however, they were treacherously murdered by Simeon and Levi, brothers of Dinah. For this deed Jacob rebuked his sons. It is assumed by Wellhausen and many other scholars that Dinah is the eponym of an Israelitish clan whose absorption by marriage in the city population of Shechem was avenged by the kindred tribes of Simeon and Levi with a ruthlessness to which their own dissolution was afterward traced. But this view is rejected by Ed. Meyer, who deems it no more justifiable than it would be to interpret Helena as a Greek tribe in danger of being absorbed by the Trojans, and who prefers to think of her as a mythical figure. The author seems to have regarded the Hivites as uncircumcised. This, however, may be due to ignorance of the customs of an earlier population that had completely disappeared. See CIRCUMCISION.

Consult Meyer, *Die Israeliten und ihre Nachbarstämme* (1906), and Wellhausen, *Israelitische und jüdische Geschichte* (7th ed., 1914).

DINANT, dē'nān' (Gall., fortress on the water, from its situation on the Rance). A town in the Department of Côtes-du-Nord, France, situated on the Rance, 30 miles northwest of Rennes and 14 miles south of Saint-Malo (Map: France, N., C 4). It stands on the summit of a steep cliff of granite, with the Rance flowing through a valley 250 feet below and crossed by a fine stone viaduct 130 feet high and 810 feet long. The town is surrounded by old walls, pierced by four gates, and was defended by the castle of the Countess Anne, still in an excellent state of preservation, part of it being now used as a prison. In the older district the streets are crooked, narrow, and steep, many of the buildings being wooden constructions, though picturesque in some places. The cathedral of St. Sauveur is a beautiful building, the north side being in the Gothic, the south in the Romanesque style. In the north transept an inscription points out where the heart of Bertrand Du Gues-

clin is buried. The church of Saint-Malo contains a painting by Archenault, "Christ Triumphant over Sin." Dinant has an interesting museum. Its industries include the manufacture of agricultural implements, fine linen, sailcloth, cotton and woolen goods, beet-root sugar, and cider. It also builds barges which are used in its coasting and inland trade on the Rance. Pop., 1901, 10,534; 1911, 11,410. Dinant dates from the Roman period; the chief event in its history was the siege by the English, under the Duke of Lancaster, in 1359, when it was captured and later retaken by Du Guesclin. Consult Bazouge, *Guide du voyageur dans la ville de Dinant et ses environs* (Dinant, 1875).

DINANT, dē'nān' (Gall., fortress on the water, from its situation on the Meuse). A town of Belgium, in the Province of Namur, situated on the Meuse, 17 miles by rail from Namur (Map: Belgium, C 4). The most noteworthy buildings of Dinant are the church of Notre Dame, an ancient and richly decorated Gothic structure, and the city hall, once the palace of the princes of Liège. Dinant has several mills for sawing the black marble found in the vicinity, paper mills, carpet factories, breweries, tanneries, factories for the production of metal ware, and glassworks. In the Middle Ages Dinant was famous for its copper ware, or *dinanderie*. Dinant, which dates from the sixth century, has suffered greatly from frequent sieges. In 1466 Philip, Duke of Burgundy, attacked it with a strong force and drowned a large number of its inhabitants after the town was taken. In 1554 and 1675 it was taken and plundered by the French. It is now one of the most popular Belgian summer resorts. Pop., 1900, 7512; 1910, 7690. Consult Pirenne, *Histoire de la constitution de la ville Dinant au moyen âge* (Ghent, 1889), and Hachez, *Histoire de Dinant* (Cour Saint-Etienne, 1894-96).

DINAPUR, dē'nā-pūr'. An important military station in the Patna district, Province of Behar and Arissa, British India, on the right bank of the Ganges, 10 miles west of Patna (Map: India, D 3). It contains spacious barracks. In 1857 it was the scene of the mutiny of three Sepoy regiments. It has cabinet factories, iron foundries, and oil presses. Pop., 1901, 33,699; 1911, 31,025.

DINARCHUS (Gk. Δειναρχος, *Deinarchos*) (c.361-291 B.C.). A Greek orator of moderate ability, born in Corinth. Going early to Athens, he studied with Demetrius Phalereus and Theophrastus and became a writer of speeches. Of these there were many, but only three are extant; these bear the titles *Against Demosthenes*, *Against Aristogeiton*, *Against Philocles*, and were used in the prosecution of the three men named on the charge of having accepted bribes from Harpalus (q.v.). His most successful period was that of the governorship of Demetrius Phalereus (317-307), after which he retired as an exile to Chalcis, returning to Athens in 292 B.C. Dionysius of Halicarnassus (q.v.), who wrote a treatise on the life and speeches of Dinarchus, held that 58 out of 85 speeches current under his name were genuine. For his speeches, consult: Mätzner, text and commentary (Berlin, 1842); Thalheim (ib., 1887); Blass, *Attische Beredsamkeit* (Leipzig, 1887-93).

DINARD, dē'nār', or **DINARD-SAINT ENOGAT, sǎn'tā'nó'gǎ'.** The capital of a canton in the Department of Ille-et-Vilaine, France,

on the estuary of the Rance, opposite Saint-Malo and Saint-Servan. It is the most fashionable sea-bathing resort in Brittany and is a picturesque modern town, situated on a rocky promontory with beautiful views. It has beautiful villas and summer cottages, a fine sandy beach, well-appointed bathing establishments, a casino, an American and English colony, and is greatly frequented by foreign tourists. Saint-Enogat, an ancient village to the northwest, has a fine beach on the Bay of Saint-Malo. Pop., 1911, 7003.

DINARIC RACE, *dī-nār'ik* (from the Dinaric Alps). A name applied by Deniker to the dark, short-headed, tall people along or near the coast of the northern Adriatic, especially in Bosnia, Dalmatia, and Croatia; also in Roumania, Venetia, among the Slovenes, the Ladinis of the Tirol, the Romansch of Switzerland, and in parts of France. Stature, 1.68 to 1.72 meters average; cephalic index, 85-86; brown or black wavy hair, dark eyes, straight eyebrows, long faces, delicate aquiline noses, tawny skin. Consult Deniker, *Races of Man* (London, 1900), and Ripley, *Races of Europe* (New York, 1899).

DINCKLAGE - CAMPE, *dīnk'lā-ge-kām'pe*, AMALIE (EMMY) VON (1825-91). A German novelist. She was born on the family manor at Campe, Hanover. She traveled extensively in Europe and also visited the United States (1880). Her fine powers of observation and the poetic beauty of her descriptions, particularly of the Ems River region, in which she lived, won for her the title *Die Dichterin des Emslandes*. Her novels, tales, and romances, several of which have been translated, include: *Tolle Geschichten* (1870); *Emsland-Bilder* (1881); *Jung Alarichs Braut* (1890).

DINDINGS, *dīn-dīngz'*, THE. A portion of the British colony of the Straits Settlements (q.v.), consisting of the small island of Pangkor, off the west coast of the Malay Peninsula, and a portion of Perak (q.v.) (Map: Burma, D 6).

DINDORF, *dīn'dōrf*, KARL WILHELM (1802-83). A German classical scholar. He was born in Leipzig, studied at the University there, and early completed Invernizzi's edition of Aristophanes (vols. vii-xiii, 1820-34), and himself prepared a much smaller edition of that poet (2 vols., 1827). In 1827, too, he edited Athenæus. From 1828 to 1833 he was professor of the history of literature in the University of Leipzig. In 1833 he resigned his university post, and devoted himself to study and publication for many years, being with his brother Ludwig (q.v.) and K. B. Hase, an important contributor to the republication of Stephanus' *Thesaurus Linguae Graecae* (Paris, 1831-65). He prepared a collective arrangement of the text of all the Greek dramatists in his *Poetae Scenici Graeci* (1830; 5th ed., 1869). Later he edited them separately, with notes and scholia (Oxford, 1832-63). His *Metra Aeschylī, Sophoclis, Euripidis et Aristophanis* (1842) is a valuable study, and his lexicons to Sophocles (1870) and Aeschylus (1873-76) are useful. In 1846-51 he published at Oxford an edition of all the speeches of Demosthenes, with notes and the Greek scholia (9 vols.). For the *Corpus* of writers of the Byzantine period, of which Niebuhr was general editor, he edited several historians, among them Procopius. In 1846-51 he published a notable edition of Demosthenes (9 vols.). In 1867-71 he edited Eusebius of

Cæsarea. He is to be ranked among the leading Hellenic scholars of recent times. Consult Sandys, *A History of Classical Scholarship*, vol. iii (Cambridge, 1908).

DINDORF, LUDWIG AUGUST (1805-71). A German classical scholar of distinction. He was born in Leipzig and studied under Gottfried Hermann. In 1823 he began his literary activity by publishing, with full critical commentary, Xenophon's *Symposium* and *Agésilas*. From this time to his death he kept almost equal pace with his brother Wilhelm (q.v.) in editing critical texts, although he centred his attention chiefly on the historians. He published editions of *Thucydides* (1824), *Xenophon* (1853-66), *Diodorus Siculus* (last ed., 1867-68), *Pausanias* (1845), *Polybius* (1866-68), *Dio Cassius* (1863-65), *Zonaras* (1868-75), the collection of *Historici Graeci Minores* (1870-71). For the *Corpus Scriptorum Historiae Byzantinae* he edited *Johannes Malalas* (1831) and the *Chronicon Paschale* (1832). He also published editions of *Hesiod* and *Euripides* (1825), and, with his brother and K. B. Hase, prepared a revised edition of Stephanus' *Thesaurus Graecae Linguae* (Paris, 1831-65). Consult Bursian, *Geschichte der klassischen Philologie in Deutschland* (Munich, 1883), and *Allgemeine deutsche Biographie*, vol. v (Leipzig, 1877).

D'INDY, P. M. T. V. See INDY.

DINDYMENE (Lat., from Gk. *Δινδυμήνη*). The by-name of Cybele (q.v.), from Mount Dindymus in Phrygia, which was sacred to the goddess.

DINEIR, *dē-nā-ēr'*; also known as GEYIKLAR, the place of stags. The ancient Celænæ. A town in Asia Minor at an altitude of 2845 feet in the Province of Aidin. Its site lies close to the headwaters of the Mæander River. This position also commands the road from the Lycus valley to the interior. The junction of these two natural routes made of Celænæ one of the most important centres of commerce and civilization in the centuries following Alexander's death. The same causes are operating again to bring about Dineir's modern prominence. The town is the most convenient outlet for the products of the Anatolian plateau. It is at present the easternmost terminal of the Aidin Railway running from Smyrna. Plans are now (1914) considered to make it the northern terminal of the railroad built inland from Adalia. The environs of Dineir constitute a rich agricultural district. Numerous flour mills are operated in the town. The dwellings present the peculiarity of being partly constructed of blocks of marble and sculpture obtained from the ruins of the ancient town. Pop., 2000, of which 1200 are Turks.

DINGAAN, *dīn-gān'*. A chief of the Zulus. See ZULULAND.

DINGELSTEDT, *dīng'el-stēt*, FRANZ VON (1814-81). A German poet, dramatist, and novelist, born at Halsdorf, Hesse. He won popular favor, but shocked official Germany by his liberal *Lieder eines kosmopolitischen Nachtwächters* (1841). His *Gedichte* (1845) were less offensive and more poetic. His somewhat frivolous manner of dealing with serious problems is shown in his later sketches of travel, *Das Wanderbuch* (1847), and his society novel, *Die Amazone* (1868). He adapted Molière and Shakespeare to the German stage, wrote *Studien und Kopien nach Shakespeare* (1858) and a successful tragedy, *Das Haus der Barneveldt*

(1851). He won great success as a theatrical director at Munich, Weimar, and Vienna, was ennobled in 1867, and made Baron in 1876. His complete works appeared in 12 vols. in 1877. Consult his autobiography under the title of *Munchner Bilderbogen* (1879).

DINGLE, din'gl. A seaport, the most westerly town in Ireland, in County Kerry, 39 miles west-northwest of Killarney (Map: Ireland, A 4). It has an antique aspect, some of the houses having been built in the sixteenth century, in the Spanish style, with stone balconies, etc. The chief exports are corn and butter to Liverpool. Dingle was incorporated in 1585. Pop., 1901, 2,142; 1911, 2,219.

DINGLE, den'glā. A town of Panay, Philippines, in the Province of Iloilo, situated on the Jalaur River 18 miles north of Iloilo. There are gold deposits in the vicinity. Dingle was founded in 1825. Pop., 1903, 12,129.

DINGLEY, NELSON, JR. (1832-99). An American Republican politician and journalist. He was born in Durham, Me., graduated at Dartmouth in 1855, and in the following year became proprietor of the *Lewiston Journal*, of which he was also editor for 20 years. From 1862 to 1873 he served in the State Legislature, being Speaker in 1863 and 1864, and in 1874-75 was Governor. From 1881 until his death he was a member of Congress, where he was a specialist in tariff legislation and was the framer of the tariff law of 1897, which bears his name. In 1898 he was appointed a member of the Joint High Commission on controversies between Canada and the United States.

DINGLINGER, ding'ling-ēr, JOHANN MECHTOR (1664-1731). A German goldsmith and jeweler. He was born at Biberach and in 1693 settled at Dresden. Here he became a favorite with Augustus the Strong, who appointed him court goldsmith, and also with Peter the Great, who twice was his guest while on a visit to Dresden. Dinglinger's only authentic works are in the Green Vaults in Dresden. They are characterized by perfection of workmanship, variety of technique, and vivid imagination; but are overloaded with ornament. Among the principal are "The Court of the Grand Mogul," a splendid table service consisting of more than 130 figures (1701-09); a chalcedony vase representing the "Bath of Diana" (1720); the so-called "Obelisk Augustalis" of enamel, gold, and precious stones; and a cabinet piece illustrating "Life's Joys." Consult the monograph by Sponsoel (Stuttgart, 1904).

DINGO, din'gō (native Australian name). The wild dog of Australia (*Canis dingo*), remarkable not only for being the only species of dog existing both wild and domesticated, but also for being the only carnivorous placental mammal in Australia. Some writers have regarded the dingo as an example of the domestic dog run wild, but the occurrence of its remains in the Quaternary strata of Australia, and even in cavern deposits of Pleistocene time, seems to make any such position untenable, though it is not impossible that the dingo may have been brought to Australia by man when he first set foot on that continent. The improbability of Australia possessing a native placental mammal of such large size, and the fact that it is not found in Tasmania or New Zealand, lend force to the belief that it is a dog of Asiatic origin brought to Australia by the Malays, who visited the northeast coast in their proas in his-

toric ages. With the advance of civilization the dingo, like the native races to which it is a companion, has gradually disappeared from large parts of southern and eastern Australia. As it is a serious menace to flocks of sheep, the settlers have made war upon it, and its extermination as a wild animal is not improbable. Its local extermination, however, has more than once been followed by so great an increase of grass-eating marsupials, upon which it preyed, that special efforts have been necessary to kill them off in turn.

The dingo is about 2½ feet in length and somewhat less than 2 feet high. The ears are rather large and erect, and the tail is bushy. The color varies from pale brown to black, tawny shades being common. Windle says an average skull measures 302 millimeters in length and 172 millimeters in width. The dingo does not bark or growl in its wild state, but utters wolfish howls, especially at night. Tame dingoes, placed among other dogs, however, soon learn to bark. They are great hunters, pursuing their prey in packs and running with the head carried high and the ears erect. They kill more than they can possibly use, are cunning and courageous, and themselves afford good sport for a pack of hounds.

The dingo is domesticated by the native Australians in all parts of the continent, the puppies being found in hollow trees and similar places where the female "nake their lairs. They are not only faithful companions, but are of the greatest use to the natives, by assisting them in finding opossums, rats, snakes, and lizards for food. Nevertheless the black fellows hunt, kill, and eat the wild dingoes. A dingo's blood has been used to make the "celpie, the most prized of all cattle dogs. They are trained never to bark. Consult Smyth, *The Aborigines of Victoria* (Melbourne, 1878), and *Wanderings* (London, 1865). See DOG, and Plate of WOLVES AND WILD DOGS.

DINGRAS, dën-gräs'. A town of Luzon, Philippines, on the Grande de Laoag River in the Province of Ilocos Norte, 10 miles southeast of Laoag. It is situated in a fertile plain, surrounded by mountains, which is subject to inundations. Dingras was founded in 1598. Pop., 1903, 15,792.

DINGWALL. A royal burgh, the county town of the united counties of Ross and Cromarty, Scotland, at the head of the Cromarty Firth, 18½ miles northwest of Inverness (Map: Scotland, D 2). It lies low, amid rich, fertile, and well-wooded ground, at the entrance to the beautiful valley of Strathpeffer, the famous sulphurous springs of which are 5 miles to the west. A short canal brings vessels drawing 9 feet of water up to the town. Its prosperity depends on agriculture. Pop., 1901, 2519; 1911, 2639. To the west is a vitrified fort on a conical hill, and there are traces of an ancient castle where the earls of Ross held their courts.

DIN'IA. See DIGNE.

DIN'IAS (Lat., from Gk. Δεινίας, *Deinias*) and **DERCYLLIS** (Lat., from Gk. Δερκυλλίς, *Derkyllis*). Characters in an old Greek novel, in 24 books, now lost, entitled *Incredible Things in Thule*, by Diogenes Antonius, a Syrian of the second century B.C. The work served as a source for various later authors.

DINICHTHYS, di-nik'this (Neo-Lat., from

Gk. *δεινός*, *deinos*, terrible + *ἰχθύς*, *ichthys*, fish). A genus of fossil dipnoan fishes of large size belonging in the order Arthrodira, and found in the uppermost Devonian and Lower Carboniferous rocks of North America, and less commonly in Europe. The body is estimated to have had a length of 15 to 18 feet, but few traces of other portions than the heavy armor plates of the head and anterior part of the trunk have been observed. The general form is similar to that of *Coccosteus*, with which it is quite closely related. The head was often over 3 feet in width and 4 or more feet long, and the bones of the skull were heavy plates, well joined together to form a solid dorsal head shield. The eyes were of large size, as indicated by the form of the orbital notches in the margin of the head shield. The dentition, which resembles that of the modern *Protopterus*, was very formidable. It consisted, in the upper jaw, of two large anterior triangular teeth that functioned as incisors, and two lateral oblong plates with sharp enameled cutting edges. The lower jaws are very strong and have at their anterior ends prominent sharp teeth that interlock with those of the upper jaw, and behind these the upper edges of the jaws are hardened by enamel and sharpened to form very efficient smooth or denticulate cutting edges, that must have engaged with the sharp edges of the upper jaw in mastication. The plates of the ventral surface of the head and those of the anterior part of the trunk resemble the corresponding plates in the genus *Coccosteus*, and there is a hinge joint between the head plates and the body plates.

The larger number of these fossils have been found in the Upper Devonian Cleveland shale of Ohio, from which formation they were originally described by Prof. J. S. Newberry. The best-known species are *Dinichthys hertzeri* and *Dinichthys terrelli*. Consult: Newberry, "The Palaeozoic Fishes of North America," in *Monograph of the United States Geological Survey*, vol. xvi (1890); Dean, *Fishes, Living and Extinct* (New York, 1895); Dean, "Contributions to the Anatomy of *Dinichthys*," etc., in *Transactions of the New York Academy of Sciences*, vol. xv (1896); vol. xii (1894) and vol. xvi (1898); id., "Studies on Fossil Fishes," in *Memoirs of the American Museum of Natural History*, vol. ix (New York, 1909). See LUNGFISH.

DINIZ DA CRUZ E SILVA, *dé-nêz' dâ krôoz ê sêl'vâ*, ANTONIO (1731-99). A Portuguese heroico-satirico-comic poet, born in Lisbon. He is considered one of the revivers of the poetry of Portugal (for he helped found the *Arcadia Lusitana*), and has been called the "Portuguese Pindar." His works are full of local color, and his odes are fine, but his admiration for the classics of antiquity was such that instead of drawing from them his inspiration he contented himself too often with mere imitation. His best work, *O Hyssope* (1802, and frequently since), is not open to this criticism. Diniz was a keen observer, and in this work, to which he owes his immortality, he pictures faithfully and ruthlessly the vanities, intrigues, and blind ignorance of the society of an important provincial town dominated by two antagonistic cliques—one supporting the commandant of the garrison and the other the Bishop of the diocese. The work was translated into French prose by Boissonade and has gone

through two editions (Paris, 1828, 1867). Selections have appeared in English in the *Foreign Quarterly Review* and in the *Manchester Quarterly* (1896). The best edition of *O Hyssope* is that by J. R. Coelho (Lisbon, 1879), with introductory study of the poet and his works. His collected works are entitled *Poesias* (6 vols., Lisbon, 1807-17).

DINIZULU. See ZULULAND.

DIN'KA (native name *Jyeng*). The largest negro tribe of the Egyptian Sudan, living on both sides of the White Nile between lat. 12° and 6° N. Their country covers about 40,000 square miles. They are a tall race, intensely black, and they live chiefly from their numerous herds of cattle. Polygamy is practiced. The men wear practically no clothes and both sexes extract the two lower incisor teeth. Being brave warriors, they furnish the best material for the Sudanese regiments. The most complete grammar of their language is that of Mitterutzner (Brixen, 1866). On their manners and customs, consult: Schweinfurth, *In the Heart of Africa*, trans. by Frewer (London, 1873); Kaufmann, *Schilderungen aus Central Afrika* (Brixen, 1862); Count Gleichen, *The Anglo-Egyptian Soudan* (London, 1905).

DINKARD, *dên-kîrd'* (Pahlavi *Dinkart*, acts of religion). A collection of facts concerning the Zoroastrian religion, compiled shortly after the Mohammedan conquest of Persia. It has been edited, with English and Gujerati translation, by Peshotan Behramji Sanjana, vols. i-xiii (Bombay, 1874-1912).

DINKEY, ALVA CLYMER. An American business man, born at Weatherly, Pa. After receiving a public-school education he became connected with the Carnegie steel interests in Pennsylvania, being promoted through various positions to be general superintendent of the Homestead Steel Works in 1901. In 1903 he became president of the Carnegie Steel Company.

DIN'MONT, DANDIE. An eccentric border farmer in Scott's *Guy Mannering*.

DINOCERAS, *dî-nô's'ér-as*. See TINOCERAS.

DINO COMPAGNI, *dé-nô kôm-pâ'nyé*. See COMPAGNI, DINO.

DINOC'RATES (Lat., from Gk. *δεινοκράτης*, *Deinokratēs*). A Greek architect, who, according to Vitruvius (ii, 1-4), visited the camp of Alexander the Great with letters of introduction, but was unable to secure an audience. Relying upon his athletic figure, he at length decked himself in the costume of Heracles, with lion's skin and club, and thus attracted the notice of the King. He then proposed to Alexander to carve the huge mass of Mount Athos into a seated human figure, holding a city in one hand and a vessel of water in the other, into which all the rivers of the mountain should flow. The work was never attempted, but Dinocrates was taken into the favor of the King and employed as architect in the foundation of Alexandria. He was also employed by the Ephesians in the reconstruction of the temple of Diana (see DIANA, TEMPLE OF). He constructed also the funeral pyre of Hephaestion.

DINOR'NIS (Neo-Lat., from Gk. *δεινός*, *deinos*, terrible + *ὄρνις*, *ornis*, bird). A genus of gigantic, recently extinct, ratite birds, the typical moas, taken as the type of the family Dinornithidae. See MOA, DINORNIS ANIMALS.

DINOSAURIA (Neo-Lat., from Gk. *δεινός*,

deinos, terrible + *σαῦρος*, *sauros*, lizard). An order of fossil reptiles, found only in rocks of Mesozoic age, and containing some of the most wonderful and bizarre land animals that have ever lived. In general, the dinosaurs present the same reptilian characters as do the crocodilians and pterosaurians, which have been derived from the same original stock, and within the order the form is so variable that it is difficult to find reliable distinctive characters. The more primitive genera can scarcely be distinguished from the generalized crocodiles, others resemble the rhynchocephalians, others the pterosaurians, and still others are far removed by specialization along particular lines and afford most remarkable and extravagant forms. The closest living allies of the dinosaurs are the crocodiles and the ratite birds (ostrich, etc.), which, with the more primitive dinosaurs, were probably descended from a common ancestral stock in Triassic times, such as the *Pseudo-suchians*.

TOOTH OF DI-
PLODOCUS.

Section of maxillary bone of *Diplodocus longus*, showing functional tooth (fourth) in position and five successional teeth (2, 3, 4, 5, 6) in dental cavity; a, outer wall; b, inner wall; c, c, cavity; f, foramen.

of birdlike structure, often with anterior and posterior elongation of the elements. The limbs are fitted for locomotion on land; the forward pair is often reduced in size so that locomotion is bipedal. Reduction of the number of toes on the hind feet to three is common. In some gigantic genera the tail was unusually strong and with the hind limbs formed a tripod support for the animal, which was thus enabled to raise its head to a height sometimes of 30 feet above the ground and to overlook the vegetation of the marshes in which it wallowed. The dentition of dinosaurs is fitted for both carnivorous and herbivorous food. Beaklike structure of the jaws is common. The teeth are often implanted in sockets, and in some genera they appear in successional series. The head of dinosaurs is usually disproportionately small, and the brain is always of very small size and low degree of convolution, indicating

SKULL OF CLAOSAURUS ANNECTENS.

an inferior grade of intelligence in these animals. In some forms with small head, long neck, heavy body and hind quarters, and long heavy tail, where the hinder part of the body overbalances by far the forward portion, as in

Brontosaurus, *Diplodocus*, *Scelidosaurus*, and *Stegosaurus*, the neural ganglion in the sacrum is many times larger than the cephalic ganglion

SKULL OF CERATOSAURUS.

or brain, a condition necessitated by the great mass of the body that must be innervated from the sacral ganglion in these animals.

In habits the dinosaurs were terrestrial and often amphibious, and the structure of the tail in some genera indicates its use as a swimming organ. Some were of graceful, birdlike action, walking, running, or leaping on their three-toed hind limbs. Others were heavy, clumsy beasts, walking or crawling on their solidly built four legs. Dinosaurs vary greatly in size. The smallest are of the size of a chicken. The largest are the greatest land animals ever known to have existed, with lengths of 60 to 70 feet,

CEPHALIC AND SACRAL GANGLIA.

Drawings of casts showing the expansions of the spinal cord of *Stegosaurus ungulatus*. 1. Cast of neural cavity of sacrum; a, anterior end; p, posterior end at exit of neural canal in last sacral vertebra; f, f', f'', foramina between the sacral vertebrae. 2. Cast of brain cavity of same animal; c, cerebral hemispheres; cb, cerebellum; m, medulla; ol, olfactory lobes; on, optic nerve; op, optic lobes.

heights of 10 to 20 feet, and weights estimated to have varied from 20 to 25 tons. Dinosaurs appeared in the early Triassic time, and during the Jurassic and Cretaceous periods they ruled the land, but towards the end of the Cretaceous they began to decline, and they finally gave way to the early mammals. The remains of the latest members of the order are found in the uppermost formations of the Cretaceous, viz., the Laramie group of western America. Their remains have been found in the Mesozoic rocks of Europe, southern Asia, South Africa, North Australia, North and South America, and the most noted localities whence they have been obtained are those of Bernissart in Belgium, and the Rocky Mountain region of North America. The order Dinosauria is divided into three suborders, some of the peculiarities of which are here given. They are the Sauropoda, Theropoda, and Predentata.

Sauropoda. This group resembled the crocodiles and rhynchocephalians in the structure of its skeleton and the proportions of its parts. It includes the gigantic herbivorous genera: *Atlantosaurus*, *Cetiosaurus*, *Brontosaurus* (q.v.), and *Diplodocus* (q.v.), with very small head, long neck, heavy trunk supported on strong planti-

DINOSAURS

1. SKELETON OF DIPLODOCUS (Order Sauropoda).
- 2-5. Restorations, after Osborn and Knight
2. CERATOSAURUS (Order Theropoda).
3. STEGOSAURUS (Order Ornithomimidae).
4. HADROSAURUS (Suborder Ornithomimidae).
5. TRICERATOPS (Order Ceratopsia).

grade five-toed fore and hind limbs of equal size, and with a heavy long tail. The teeth are long, spatulate, and spreading. The bones are solid and heavy, and the pubis is simple. This group is of Upper Jurassic and Lower Cretaceous age.

Theropoda. Carnivorous dinosaurs with cutting teeth in sockets. Their skeletons are of rather delicate construction, and their vertebræ and limb bones are hollow. Their five-toed fore limbs are of small size and apparently of little use as locomotory organs, but their three-toed hind limbs are strong, and the toes are furnished with prehensile claws. These dinosaurs were digitigrade, and they walked as do birds or leaped as do the kangaroos. The pelvic bones are elongated. Examples of this suborder are *Anchisaurus*, *Ceratops*, *Tyrannosaurus*, and *Megalosaurus* (q.v.). *Hallopus*, a leaping dinosaur from the Jurassic of Colorado, and the birdlike *Compsognathus*, one of the smallest dinosaurs, from the Jurassic lithographic limestones of Solenhofen, Bavaria, also belong in this division.

Predentata. Here are included the most specialized and hence the most extravagantly formed of dinosaurs. They were all herbivorous animals that walked on either four or two feet. Some of them undoubtedly ran with great rapidity on their hind legs, using the tail as a balance after the manner of certain modern lizards. In all of them the pelvis is provided with a postpubic process, a character found in no other reptiles, and the ilium and ischium are elongated and variously modified. Another distinctive character is the presence of a pre-dentary bone on the anterior end of the mandible which has a beaklike tip. Accordingly the teeth are absent from the front of the jaws and are restricted to the posterior portions. The teeth are compressed, have crenulated edges, and they are frequently replaced by successional teeth. The Predentata comprise three divergent lines of descent—Stegosauria, Ceratopsia, Ornithopoda.

In form the Stegosaurian dinosaurs resemble most closely the Sauropoda. Their vertebræ are all biconcave, their heads are very small, and the hinder parts of their bodies are enormously developed. Many of them were armored. *Omosaurus*, from the Upper Jurassic of England, has strong dorsal spines; *Polacanthus*, of the English Wealden, has the lumbar sacral region inclosed in solid armor plate; *Scelidosaurus*, of the English Lower Lias, has a row of small vertical plates along the dorsal line. The extreme of ornamental armor is seen in *Stegosaurus* (q.v.) from the Upper Jurassic of Colorado and Wyoming, which has a row of heavy, large triangular bony plates extending from the back of the head along the back to the tip of the tail.

Ceratopsia. This group includes the horned dinosaurs, land reptiles of gigantic size and formidable appearance, which were evolved in late Mesozoic time after the dinosaur race had begun to decline. They are probably highly specialized descendants from the Stegosaurian race. Their remains have been found in the Upper Cretaceous rocks of Europe, but the best material has come from the Laramie group of Wyoming and Colorado. The prominent feature of these animals is the large size of the head. In *Triceratops* (q.v.), which attained a length of 25 feet, the head has a length of 6 feet, and

it is provided with three formidable horns and with a broad posterior expansion or crest, formed from the parietal bones, that projects some distance over the neck. The jaws have strong beaks in front and two-rooted teeth in their posterior portions. The skeletons of these dinosaurs are heavily built, the bones are solid, the five-toed fore limbs and the three or four-toed hind limbs are about equal in size, the feet were digitigrade, and the toes were hoofed like those of a rhinoceros. The body was protected by a thick hide, sometimes armored with bony plates, and the tail was smaller than in any other dinosaurs. The best-known genera are *Agathaumas*, *Triceratops* (q.v.), and *Sterrhophylus*.

Ornithopoda. These are the most bird-like of the dinosaurs, with small five-toed fore limbs and well-developed three-toed hind limbs. All the limb bones are hollow. They were unarmored, herbivorous animals, with bipedal walking, running, or leaping motion. *Iguanodon* (q.v.), of the Belgian Jurassic, with a length of 20 feet, is perhaps the best-known genus. *Claosaurus* or *Thespesius* (q.v.), from the North American Cretaceous rocks, attained a length of 35 feet. *Hadrosaurus* (q.v.), from the Laramie group, had a spoonbill beak, like that of *Ornithorhynchus*. Here, also, belongs *Nanosaurus*, the smallest-known dinosaur, which was scarcely as large as a domestic fowl, found in the Upper Jurassic rocks of Colorado.

Fossil remains of dinosaurs are to be seen only in the larger museums of the country. The American Museum of Natural History in New York City has the finest series of skeletons, many of which are accompanied by water-color restorations of these animals. Other museums where dinosaurs may be seen are the United States National Museum at Washington, Peabody Museum of Yale University, Carnegie Museum at Pittsburgh, where a complete skeleton of *Diplodocus* is mounted, the Field Columbian Museum at Chicago, and the museum of the University of Wyoming at Laramie.

DINOTHERIUM (Neo-Lat., from Gk. *δεινός*, *demos*, terrible + *θηρίον*, *thērion*, beast, diminutive of *θήρ*, *thēr*, wild beast). A genus of fossil proboscideans, indirectly allied to the modern elephant and the extinct mastodon, of which remains have been found in the Miocene and Pliocene rocks of Europe. The old proboscidean stem early became divided into two main branches, one of which includes the mastodon and modern elephants, and the other, the present animals. The dinotheres entered Europe with the mastodons in the Lower Miocene, continued with but little change into the Pliocene, and then died out. The skull, which is essentially elephantine, is longer, lower, and tapers more in front than does that of the modern elephant. The structure of the nasal bones and of the front of the cranium indicates that the animal had a proboscis, which was not, however, so prominent an organ of prehension as is that of the elephant. The molar teeth resemble those of the mastodon in structure, though they are smaller and have fewer transverse ridges on the crowns. The upper incisors, which attain to such great developments of tusks in the mastodon and elephant, are absent in the dinotherium, but the lower incisors, together with the fused ends of the mandibles, are turned downward and backward to form a pair of strong tusks, comparable with, though not at all analogous to, those of the walrus. The bones which have been found associated with these dinotherium skulls, and which probably belong to individuals of the same genus, are of massive build like those of other proboscidea, and indicate that the dinotherium lived under semiaquatic conditions, somewhat like the hippopotamuses. This perhaps accounts for the reason of their migration to America, the land bridges being doubtless passable only by terrestrial animals. The largest species of dinotherium lived in Pliocene time and rivaled in size the mastodon and mammoth. The skulls of this genus are found quite abundantly in the Miocene deposits of central Europe, in the Lower Pliocene of India and the Upper Pliocene of Greece, and are often associated with remains of the rhinoceros. No dinotherium remains have yet been found in America. See MAMMOTH; MASTODON.

DINSMORE, CHARLES ALLEN (1860–). An American clergyman and Dante scholar, born in New York City. He served with the United States engineers in the survey of the Mississippi River (1881–82), graduated from Dartmouth College in 1884, and studied theology at Yale University. Ordained to the Congregational ministry in 1888, he was pastor of churches in Whitneyville and Willimantic, Conn., and of Phillips Church, Boston. In 1905 he accepted a call to the First Church of Waterbury, Conn. He lectured at Yale Divinity School (1904) and at Bowdoin College (1908) and wrote: *The Teachings of Dante* (1901); *Aids to the Study of Dante* (1903), both of which have been translated into Japanese;

Atonement in Literature and Life (1906); *The New Light on Old Truth* (1912).

DINTER, dīn'tēr, CHRISTIAN FRIEDRICH (1760–1831). A German pedagogue and author, born at Borna, near Leipzig. He studied theology and pedagogy at Leipzig, held several pastorates, was appointed director of the Teachers' Seminary at Dresden-Friedrichstadt in 1797, and became professor of pedagogy and theology at the University of Königsberg in 1822. He was liberal in his religious views and practical in his methods of education. His lectures and writings by remarkable clearness of as one of the most active and influential pedagogues of the period of rationalism. He produced more than 60 distinct works. They include: *Die vorzüglichsten Regeln der Katechetik* (1802; 13th ed., 1862); *Makuna, ein Buch für Mutter* (1818; 5th ed., 1860); *Unterredungen über die Hauptstücke des lutheranischen Katechismus* (1806–23; frequently reprinted). Consult Amelung, *Dintess Grundsätze der Erziehung und des Unterrichts* (Plauen, 1881), and Fröhlich, in Gressler's *Klassiker der Pädagogik*, vol. xxi (Langensalza, 1901).

DIN'WIDDIE, EDWIN COURTLAND (1867–). An American temperance advocate, born in Springfield, Ohio. He was educated at Wittenberg and Grove City (Pa.) colleges and was ordained to the Evangelical Lutheran ministry. He was State superintendent of the Pennsylvania Anti-Saloon League from 1897 to 1899 and national legislative superintendent of the American Anti-Saloon League from then until 1907 and again after 1911. He led the attack on the army canteen which resulted in its abolishment, was responsible for the continuance of prohibition in Indian Territory and Oklahoma, and helped to effect important changes in the law relating to interstate shipments of liquor. In 1909 he was chosen vice president of the World's Prohibition Confederation at London, England. His writings include many pamphlets and magazine articles.

DINWIDDIE, ROBERT (c.1693–1770). A Colonial Governor of Virginia. He was born in Scotland, was for some time a clerk in the customs service, was appointed surveyor of customs for the Colonies, and in 1752 came to Virginia as Lieutenant Governor. He immediately busied himself with plans for the French and Indian War, then impending, and in 1753 sent Washington to demand the withdrawal of French traders and soldiers, who had established themselves on land claimed by Virginia. He was especially active in urging the cooperation of the Colonies against the French in the Ohio valley. In 1755 he helped the expedition sent to Forts Duquesne, Niagara, Frontenac, and Point. He was in continual conflict with the Colonial Legislature, which persistently refused to vote adequate funds for carrying on the war, and in consequence he advocated the imposition of an arbitrary poll tax by Parliament. This, combined with his arrogance, his avarice, and his indecision, made him unpopular, and led to his recall in 1758. Of value for this period are *The Official Records of Robert Dinwiddie, Lieutenant-Governor of Virginia, 1751–1758* (2 vols., Richmond, 1883–84).

DIO CAS'SIUS COC'CELIANUS (Gk. *Δίων Κάσσιος Κοκκεῖανός*, *Dion Kassios Kokkeianos*) (c.150–235). A celebrated Greek historian, grandson on his mother's side of Dio Chrysosto-

mus (q.v.). He was born at Nicæa, in Bithynia, but lived at Rome after 180. He held various high offices of state under the Roman emperors, was twice consul, and long enjoyed the intimate friendship of the Emperor Alexander Severus. From 229 to his death he lived at Nicæa. He is best known by his *History of Rome*, in 80 books, from the arrival of Æneas in Italy to 229 A.D.; of these 25 (36–60, covering the years 68 B.C. to 47 A.D.) have reached us fairly complete. The others are known to us only from fragments and the abridgment made by Xiphilinus, a Byzantine monk, in the eleventh century, of books 35–80. From Zonaras (q.v.) we get knowledge of the first 20 books of Dio's history. Dio's high position gave him free access to the national archives, and so on some points—especially on the Imperial epoch of Roman history—his work is of considerable value. He wrote on the model of Thucydides, to whom, indeed, he is far inferior both in vigor of judgment and acuteness of criticism; yet many passages of his *History* might be quoted as among the best samples of the rhetoric of the age in which he lived. The *History* was edited by Boissavain (3 vols., Berlin, 1895–1901). For a translation, consult *Dio's Rome: English Form*, by Foster (Troy, 1905 ff.), and Cary, *Dio's Roman History*, a translation based on Foster's version (London, 1914–). Both translations contain biographical and bibliographical material.

DIOCESE (OF. *diocise*, *diocese*, Fr. *diocèse*, Lat. *diocesis*, from Gk. *διοίκησις*, *διοικῆσις*, administration, from *διοικεῖν*, *διοικεῖν*, to keep house, from *διά*, *dia*, through + *οἰκεῖν*, *oikein*, to inhabit, from *οἶκος*, *oikos*, house, Lat. *vicus*, village, Skt. *viś*, house). In the Roman Catholic and Anglican churches, a district committed to the pastoral care of a bishop. The term was used in the civil administration of the later Roman Empire, which Constantine divided into 13 districts called dioceses and these again into 120 provinces. When the church had perfected her episcopal organization and received the recognition of the state, she modeled her territorial divisions on those of the civil administration. This adaptation appears to have been completed by the end of the fourth century. There developed an exarch or patriarch in each of the great dioceses, and a metropolitan or primate in each province, the word *παροικία*, or "parish," being applied to what we now call a diocese. At a later period the word "diocese" was transferred to the territory of a bishop's jurisdiction, and the word "patriarchate" used for the ancient diocese. In the Eastern churches the civil term "eparchy" is used to this day for a diocese. At the present time dioceses of the Catholic church are erected by the Pope in consistory. Before the erection of a diocese administrative districts not formally so constituted are styled "prefectures apostolic" and "vicariates apostolic." Dioceses are created in the Church of England by act of Parliament. In the American Episcopal church new dioceses are created by primary conventions of the clergy and laity of the district and are then admitted into union with the general convention by vote of that body. See BISHOP.

DIO CHRYSOSTOMUS (Lat., from Gk. *χρυσόστομος*, *chrysostomos*, golden-mouthed, from *χρυσός*, *chrysos*, gold + *στόμα*, *stoma*, mouth) (c.40–115). An eminent Greek sophist and rhetorician. He was born at Prusa, in Bithynia. His father, Pasierates, paid great attention to

his education, which was also enriched by travel. Dio, after residing for some time in his native town, came to Rome, where, however, he had the misfortune to excite the suspicion of the Emperor Domitian and was in consequence obliged to flee from Italy. On the accession of Cocceius Nerva (96 A.D.) he returned to Rome and was honorably received; in gratitude he assumed the cognomen (q.v.) Cocceianus. Nerva's successor, Trajan, held Dio in the highest estimation. His excellent disposition procured him many friends, while his remarkable powers of oratory excited universal admiration. He died at Rome. Dio left a very great number of orations, of which we still have 80 complete, with 15 others. They discuss questions of politics, morals, and philosophy, and are written in good Attic Greek. According to Niebuhr, he was "the first writer after Tiberius that greatly contributed towards the revival of Greek literature." Good editions of Dio's orations are those of Reiske (Leipzig, 1784), Emperius (Brunswick, 1844), Dindorf (Leipzig, 1857), and Von Arnim (Berlin, 1893–96). Consult Sandys, *A History of Classical Scholarship*, vol. i (2d ed., Cambridge, 1906), and Christ-Schmid, *Geschichte der griechischen Literatur*, vol. ii (5th ed., Munich, 1913).

DIOCLES, *διό-κλῆς*. See CISSOM.

DIOCLÉS (Lat., from Gk. *Διοκλῆς*, *Dioklēs*). A Syracusan statesman, noted for his code of laws (412–411 B.C.). He was a democratic leader, and his code, which continued in force until the Roman Conquest, in revisions by Timoleon and Hiero, tended to popular sovereignty. His failure to bury the dead, after his vain attempt to raise the siege of Himera, beset by the Carthaginians, resulted in his banishment in 408 B.C.

DIOCLETIAN, *διό-κλῆς-σαν* (GAIVS AURELIUS VALERIUS DIOCLETIANVS). A Roman emperor (284–305 A.D.). He was born of humble parents in Dalmatia (245). He adopted a military career and served with distinction under Aurelian and Probus, accompanied Carus on his Persian campaign, and finally, when the murder of Numerianus was discovered at Chalcedon, he was proclaimed Emperor in 284 by the army on its homeward march. The suspected assassin of Numerianus, the prefect Arrius Aper, he slew with his own hands, in order, it is alleged, to fulfill a prophecy communicated to him, while still a lad, by a Druidess of Gaul, that he should accede to a throne as soon as he had killed an *aper* (wild boar). In 285 Diocletian commenced hostilities against Carinus (the joint Emperor along with the deceased Numerianus), who, although victorious in the decisive battle that ensued, was murdered by his own officers, thus leaving to Diocletian the undisputed supremacy. His first years of government were so molested by the incursions of barbarians from Gaul and Germany that, in order to repel their growing aggressiveness, he took to himself a colleague—viz., Maximian—who under the title of Augustus became joint Emperor in 286. Diocletian reserved for himself charge of the eastern half of the Empire and gave the western to Maximian. Still the attacks of the barbarians continued as formidable as ever. The Empire was menaced by the Persians in the east, by the Germans and other barbarians in the west; hence, in order to provide for its permanent security, Diocletian subjected it to a still further division. In 292 Constantius Chlorus and Ga-

lerius were proclaimed as Cæsars, and the distribution of the Roman Empire was now fourfold—Diocletian taking the east, with Nicomedia as his seat of government. Maximian, Italy and Africa, with Milan as his residence; Constantius, Britain, Gaul, and Spain, with Treves as his headquarters; Galerius, Illyricum, and the entire valley of the Danube, with Sirmium as his Imperial abode. It was upon his colleagues that most of the burden of engaging actively in hostilities fell, as Diocletian seldom took the field in person. Among the conquests, or rather reconquests, that were made under his rule, may be enumerated that of Britain, which, after maintaining independence under Carausius and Allectus, was, in 296, restored to the Empire; that of the Persians, who were defeated and compelled to capitulate in 298; and that of the Marcomanni and others of the northern barbarians, who were driven beyond the Roman frontier. Diocletian, after 21 years' harassing tenure of government, desired to pass his remaining days in tranquillity. On May 1, 305, accordingly, he abdicated the Imperial throne at Nicomedia and compelled his colleague Maximian (much against the latter's will) to do likewise at Milan. Diocletian sought retirement in his native province of Dalmatia, and for eight years resided at Salona (now Spalato), devoting himself to philosophic reflection, to rural recreation, and to horticultural pursuits. Two years before his abdication he was instigated by his colleague Galerius to that determined and sanguinary persecution of the Christians for which his reign is chiefly memorable. He died in 313. Diocletian ruled as absolute monarch, but he was an able administrator. He reformed the coinage, sought to stimulate trade, and tried also to regulate the price of provisions and many other necessities of life. For the edict by which he sought to fix prices, consult Abbott, *The Common People of Ancient Rome* (New York, 1911). He adorned Rome with fine buildings; for one of these, see DIOCLETIAN, BATHS OF. Consult: Mason, *The Persecution of Diocletianus* (London, 1876); Preuss, *Kaiser Diocletian und seiner Zeit* (Leipzig, 1869); Allard, *La persécution de Dioclétien* (1890).

DIOCLETIAN, BATHS OF. Baths at Rome, the largest in the city, built by Diocletian and Maximian, opened in 306 A.D. and still used at the time of Theodoric. The ruins were converted into a Carthusian monastery, and the tepidarium (see BATH) into the church of Santa Maria degli Angeli, by Michelangelo; a circular hall at the southwest corner of the outer wall was made into the church of San Bernardo in 1594. The cloisters of the monastery are now used as a museum, the Museo delle Terme. For an account of the baths, with plan, consult Platner, *The Topography and Monuments of Ancient Rome* (2d ed., Boston, 1911).

DIOCLETIAN, EDICT OF. See DIOCLETIAN (end).

DIODATI, δῆ-δᾰ'tῆ, GIOVANNI (1576-1649). A Swiss Reformed theologian. He was born at Geneva, of a noble Italian family which, having accepted the Reformation, was driven from home by persecution. His progress in letters was so rapid that Beza caused him to be appointed professor of Hebrew in Geneva at the age of 21. He became a pastor of the Reformed church there and in 1609 professor of theology. About

this time he endeavored to spread the doctrines of the Reformation in Venice and other cities of Italy, but without success. In 1614 he went to Nîmes, where he preached for three years, and in 1618 he was sent to the Synod of Dort, to represent the Genevese church. Here his talents were so highly estimated that he was one of the divines appointed to draw up the articles of the synod. He died at Geneva in 1649. Diodati was a somewhat intolerant Calvinist, but as a preacher he was eloquent, persuasive, and conscientious. His Italian translation of the Bible—the one still generally used among the Italian Protestants—appeared in 1607; his French, in 1644. He translated into French Sarpi's *History of the Council of Trent*. Among his other works may be mentioned his *Annotaciones in Biblia* (1607); *De Fictitio Pontificiorum Purgatorio* (1619); *De Iusta Secessione Reformatorum ab Ecclesia Romana* (1628). For his life, consult Eugène de Bude (Geneva, 1869).

DI'ODO'RUS (Lat., from Gk. Διόδωρος), sur-named SICULUS. A Greek historian, born at Agyrium, in Sicily. He flourished in the times of Cæsar and Augustus—the latest date to which he refers is 21 B.C.—traveled in Asia and Europe, and lived a long time in Rome, collecting the materials of his great work, the compilation of which, he says, occupied 30 years. This work, the *Historical Library* (Βιβλιοθήκη Ἱστορικὴ, *Bibliotheca Historica*), was a universal history, in 40 books, from the beginning to 60-59 B.C. It was divided by the author into three parts. The first six books contain an account of the mythical history of all known nations down to the time of the Trojan War; the second part (books 7 to 17) covers the period from the Trojan War to the death of Alexander; the third (books 18 to 40) extended to Cæsar's Gallic wars. Books 1 to 5 are extant; so too are Books 11 to 20, containing the history from the expedition of Xerxes to the war against Antigonus; of books 21 to 40 we have only scanty extracts and quotations by other writers, e.g., Photius (q.v.). Diodorus took Ephorus for his model and set to work on his history with excellent purpose; but the annalistic arrangement of his work in itself was wholly unfitted for so comprehensive a history. Furthermore, Diodorus had no experience in practical life and military training, so that he lacked the insight necessary to carry out his undertaking; his style is monotonous and wearisome, and he was almost wholly without critical historical judgment. Yet his work is valuable for its contents, especially since the authors from which it was compiled have been lost. The best edition is by Dindorf, revised and provided with critical apparatus by Vogel (Leipzig, 1888-93), and by Fischer (1905-06). Consult Bröcker, *Untersuchungen über Diodor* (1879), and Von Mess, in *Rheinisches Museum*, 61 (1906).

DIECIOUS PLANTS. See DIECISM.

DIE'CISM (from Gk. δι-, δι-, double + *oikos*, *oikos*, house). Primarily this word applies to that condition in plants in which the male and female organs are borne by different individuals. In its original application, however, it referred to the fact that in some seed plants the stamens and pistils are borne by separate individuals. Diecism in mosses and ferns, therefore, does not mean the same thing as diecism in seed plants. In the mosses and ferns it refers to the fact that in certain species one gametophyte (prothallium in ferns) bears

the antheridia and another the archegonia. In seed plants it refers to the fact that one sporophyte produces the stamens (microsporophylls) and another produces the carpels (megasporophylls). As thus applied, the name has no morphological significance; but in both cases it refers in a sense to a similar physiological condition. If the diœcism, as exhibited by mosses and ferns, be strictly traced into the seed plants, it is discovered that they are all diœcious, for in all of them the male cells and eggs are produced by different gametophytes. This is merely a result of heterosporry, and hence heterosporous plants are essentially diœcious, if considered from the standpoint of the sex organs.

The significance of the diœcism of seed plants is not clear, although many see in it a condition which secures all of the advantages of cross pollination. On the other hand, it is in general a primitive condition, for many gymnosperms and the most primitive angiosperms are diœcious. Although prevalently displayed by the more primitive groups of seed plants, it is by no means wanting in the highest groups, so that it is not an essential indication of either a primitive or a derived condition. There are cases in which it is evident that the diœcious habit is a derived one, since in the stamen-bearing flowers rudiments of the carpels may be found, and in the carpel-bearing flowers rudiments of stamens often occur. It is evident that in such cases the diœcious condition has come from what is called the bisporangiate condition, i.e., one in which the two sets of sporangia occur in the same flower. Diœcious flowers are necessarily monosporangiate; but flowers may be monosporangiate and yet both kinds of flowers may occur upon the same individual. The monosporangiate and diœcious conditions are therefore not synonymous.

DIOGENES, dī-ōj'e-nēz (Lat., from Gk. Διογένης) (c.412-323 B.C.). A Cynic philosopher, a native of Sinope, in Pontus. His father, Icesias, a banker, was convicted of debasing the coinage, and his son, being implicated in the matter, was obliged to leave Sinope. He came to Athens where he attached himself to the Cynics, by whom, however, his first advances were repelled. In spite of his inhospitable reception Diogenes renewed the attempt to find favor with Antisthenes; though driven away by blows, by his perseverance he at last prevailed, and Antisthenes, moved with compassion, consented to admit him as a pupil. Diogenes now plunged into the extreme of austerity and self-mortification. His clothing was of the coarsest, his food of the plainest, and was provided by the pity of the Athenians. His bed was the bare ground, whether in the open street or under the porticoes. On one occasion, in default of a better place, he took up his residence temporarily in a huge jar, *πίλος*, in the Metroun, that thereby he might show his contempt of ordinary men. His life did not, however, cost him the respect of the Athenians, who admired his contempt of comfort and allowed him a wide latitude of comment and rebuke. Practical good was the chief aim of his philosophy; for literature and the fine arts he did not conceal his disdain. He laughed at men of letters for reading the sufferings of Odysseus while neglecting their own; at musicians who spent in stringing their lyres the time which would have been much better employed in making their own discordant natures harmonious;

at savants for gazing at the heavenly bodies, while sublimely incognizant of earthly ones; and at orators who studied how to enforce truth but not how to practice it. He was seized by pirates on a voyage to Ægina and carried to Crete, where he was sold as a slave. When asked what business he was proficient in, he answered, "In commanding." He was purchased by a certain Xenias of Corinth, who recognized his worth, set him free, and made him tutor to his children. It is here that he is said to have had his famous interview with Alexander the Great. The King opened the conversation with, "I am Alexander the Great," to which the philosopher answered, "And I am Diogenes the Cynic." Alexander then asked him in what way he could serve him, to which Diogenes rejoined, "You can stand out of the sunshine." Alexander is said to have been so struck with the Cynic's self-possession that he went away remarking, "If I were not Alexander, I should wish to be D . . ." Diogenes died at Corinth, according to . . . on the same day with Alexander the Great. Diogenes was wholly concerned with practical wisdom and established no system of philosophy. He represented at its best the teaching of the cynics; to gain virtue, he held, one must avoid all physical pleasure, and must turn away from the conventions of society, as things harmful to truth and goodness, to a simpler and more natural life. Certain literary works were early attributed to him, but were recognized even in antiquity as spurious. Consult: Hermann, *Zur Geschichte und Kritik des Diogenes von Sinope* (Heilbronn, 1860); Zeller, *Philosophie der Griechen*, vol. i (1889); Windelband-Bonhöffer, *Geschichte der antiken Philosophie* (3d ed., Munich, 1912).

DIOGENES CRAB. See HERMIT CRAB.

DIOGENES LAERTIUS, lā-ēr'shī-ūs. A Greek writer, a native, perhaps, of Laërte, in Cilicia. He flourished apparently about the beginning of the third century A.D. The details of his life are not known to us. His chief work, *Lives of Philosophers*, in 10 books, is a history of Greek philosophy from its beginning. Diogenes, however, lacked the ability to handle his subject, and his interest lay rather in collecting biographical anecdotes and selecting passages from the works of his predecessors than in undertaking a critical account of the development of philosophic thought. Furthermore, he drew, not from original works, but from compendia and histories, especially from the writings of Diocles of Magnesia, author of a brief account of philosophers, and Favorinus (q.v.). Yet his work has preserved many valuable facts of which otherwise we should be ignorant. Especially interesting is the last book, which deals with Epicurus alone; it contains three letters of Epicurus to Herodotus, Pythocles, and Menæceus. The authenticity of the second letter, however, is questioned. Diogenes also composed epigrams, some of which are quoted in his larger work. The text of the *Lives* was edited by Cobet (Paris, 1850, 1862); for a commentary, consult the edition by Hübner and Jacobitz (1828-33). In Bohn's Classical Library there is a translation by Yonge. Consult Christ-Schmid, *Geschichte der griechischen Literatur*, vol. ii (5th ed., Munich, 1913). For the value of Diogenes to the student of Greek philosophy, at least on its biographical side, consult passim such a work as Ritter and Preller,

Historia Philosophiæ Græcæ (9th ed., Gotha, 1913).

DIOGENES OF APOLLONIA. A Greek philosopher, a pupil of Anaximenes and a contemporary of . . . who flourished in Athens in the first half or the fifth century B.C. He believed air to be the source of all being, and all other substances to be derived from it by condensation and rarefaction. He also recognized an intelligent principle, in that he believed air to be endowed with consciousness and intelligence, but did not distinguish between mind and matter. Of his most important work, *Περὶ Φύσεως*, *Peri Physeos*, 'On Nature,' considerable . . . in, especially in Simplicius. . . . *Philosophie der Griechen*, vol. i (Leipzig, 1892), and Ritter and Preller, *Historia Philosophiæ Græcæ* (9th ed., Gotha, 1913).

DIOGENIANUS (Lat., from Gk. *Διογενειανός*, *Diogeneianos*). A Greek grammarian of Heraclea, who lived in the middle of the second century A.D. His epitome, in five books, of the collection of glosses compiled, about a century before, by the Alexandrian grammarian Pamphilus (q.v.), is believed to have been the basis of the lexicon of Hesychius (q.v.). Diogenianus' work was known as the *Περίεργονέμης*, *Periērgonētes*, 'Poor Students' Lexicon.' A portion of the work, containing a collection of proverbs made by him, is preserved in an abridged form in the *Paræmiographi Græci*, edited by Von Leutsch and Schneidewin (1839).

DIOGNETUS (Lat., from Gk. *Διόγνητος*), EPISTLE TO. A Greek Christian work, of unknown authorship, commonly included among the Apostolic fathers (q.v.), but properly belonging to the apologetic literature of the early Church. In the Strassburg manuscript, our sole authority for the text, which was destroyed by fire in 1870, the work was attributed to Justin, but it is improbable that he was its author. The lack of external testimony to the Epistle renders the question of its date a difficult one. If we could be sure that the "Diognetus" to whom it is addressed was the teacher of Marcus Aurelius, as Lightfoot suggested, the problem would be easier. But of this we are by no means certain. Some extreme critics have conjectured that the work is a fifteenth-century forgery. Others, with much greater probability, assign it to the second, or the early part of the third, century. In view of internal resemblances some have inclined to the opinion that it proceeds from the same author as the recently recovered Apology of Aristides, which was written before 150 A.D. Date and authorship, however, remain matters of conjecture. The last two chapters are evidently a later addition and from a different hand.

The Epistle is an excellent product of Christian . . . writing, evangelical in character, . . . tone, and clothed in language which . . . almost of poetic beauty. Its contents are determined by the questions Diognetus has asked, e.g., what god the Christians worship, why they despise death, what is the explanation of their mutual love, and why their new life motive did not sooner enter the world. In replying to these inquiries the author shows special familiarity with Pauline and Johannine . . . He sets forth Christianity on its . . . placing emphasis upon godly living rather than upon correct dogmatic be-

lief. Yet he combats with vigor the errors of the Jews and Greeks, very much after the fashion of the Apology of Aristides, arguing for the superior rationality of the Christian faith.

For the Greek text, consult: K. Otto, *Corpus Apologetarum Christianorum*, ii (3d ed., Jena, 1879); for the text with Eng. trans., Lightfoot, *The Apostolic Fathers* (London, 1893); for Eng. trans., A. C. Cox, *The Ante-Nicene Fathers*, i. Consult also, in general: G. Krüger, *History of Early Christian Literature* (trans., New York, 1897); the article "Diognetus" in Smith and Wace, *Dictionary of Christian Biography*; Harnack, *Chronologie der altchristlichen Litteratur*, i (Leipzig, 1893).

DIOMEDE ISLANDS. Two small islands situated near the middle of Bering Strait, in about lat. 66° N. and long. 169° W., forming as it were stepping-stones between the nearest points of Asia and North America. They were discovered by Popof in 1711. Big Diomede, or Romanzof, pertains to Russia, but Little Diomede, or Krusenstern, belongs to the United States and affords scanty means of livelihood for its native population (90 in 1910). The United States maintains a school on the island.

DIOMEDES (Lat., from Gk. *Διομήδης*). The son of Tydeus and Deïpyle and King of Argos. He plays a prominent part in the legend of the Trojan War, where he appears as the companion of Odysseus in many adventures, such as the bringing of Achilles from Scyros, the carrying off of the horses of Rhesus, and the theft of the Palladium. At the funeral games of Patroclus he is victor in the chariot race. He played a large part too in the capture of Troy. Returning to Argos, he found that Aphrodite, in revenge for the wound which he had given her in a battle before Troy, had caused his wife to become unfaithful. In grief he left Argos and, according to the later tradition, went to Italy, where he was honored in a number of the southern cities, as Metapontum and Thurii. Arpi in Apulia, Canusium, Brundisium, and several other towns claimed him as their founder. Consult the article "Diomedes," by Bethe, in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, vol. v (Stuttgart, 1905).

DIOMEDES. In Greek legend, the son of Mars and Cyrene, and King of the Bistones in Thrace. He fed his mares upon the flesh of strangers, until Heracles, as his eighth labor, slew him and brought his mares to Eurystheus. According to one story, Heracles threw him to his mares to be devoured.

DIOMEDES. A Roman . . . of the fourth century A.D.; author of *Ars Grammatica*, an extant treatise on grammar. The work, which is in three books, is founded on the same sources as the *Institutiones Grammaticæ* of Charisius and is valuable chiefly for its quotations from earlier authorities now lost and for its comments on literary history contained in the third book and borrowed from the *De Poetis* of Suetonius. The text is printed in Keil's edition of the *Grammatici Latini* (vol. i, p. 298 ff.). On Diomedes' Latinity, consult Paucker, *Kleinere Studien*, vol. i (Berlin, 1883).

DIOMEDES, VILLA OF. The name given to one of the villas outside Pompeii, beyond the Herculanean Gate, excavated in 1771-74, and so called from the tomb of Marcus Arrius Diomedes, which faces it on the opposite side of the Street of Tombs. It was an extensive

and very completely appointed establishment, built before the time of Augustus. The occupies a lower level than the front and contains a colonnade surrounding a garden. In the wine cellar beneath the colonnade 20 skeletons were discovered in the course of the excavation, and 14 in other parts of the house. For an account of the villa, with a plan, consult Mau-Kelsey, *Pompeii: Its Life and Art* (2d ed., London, 1911).

DION (Lat., from Gk. Δίων) (c.410–354 B.C.). A Syracusan, son of Hipparinus, the brother-in-law of Dionysius the Elder, and a pupil of Plato. His lofty character secured for him the hostility of the King, Dionysius the Younger, and in 366 B.C. he was banished. Dion lived quietly at Athens for several years. When Plato, once more in Sicily, interceded with Dionysius in Dion's interest, Dion's property was confiscated, and his wife, Arete, was given to another man. Dion, now desiring to free his country from the tyrant's rule, returned to Syracuse with a small force, in 356. He took the city and expelled Dionysius, but was himself shortly after compelled to give up his power and withdraw to Italy. Being soon recalled by popular vote, he made himself tyrant of Syracuse and master of Sicily, but was assassinated about 354 by one Calippus.

DI'ONÆ'A (Lat., fem. of *Dionæus*, pertaining to *Dione*, Gk. Διώνη, *Dionē*, name of Venus). A most remarkable insect-catching plant belonging to the order Droseraceæ. The single species, *Dionæa muscipula*, is popularly known as Venus's flytrap because of the peculiarly trap-like fly-catching organ developed at the summits of its leaves. This plant is a small, relatively inconspicuous, perennial herb, growing native in bogs in North and South Carolina, and because of its interesting habits often kept in greenhouses. From the midst of the circlet of root leaves arises a slender scape 10 to 12 inches in height, at the summit of which is a cyme of small white flowers. The leaf is divided into two parts—a lower, simple, spatulate portion, above which, and separated by a narrow constriction, is the flytrap. This organ forms the bilobed upper portion of the leaf, each lobe of which is reniform, with the edge provided with spiny bristles. The lobes hinge upon the midrib and have upon their inner surfaces a few extremely sensitive hairs. When these hairs are irritated by an insect, the lobes, under favorable conditions of temperature, suddenly close, the marginal spines catching the insect after the manner of a steel trap. If the insect is caught, the trap remains closed and, by means of secretions from the glandular inner surface of the lobes, the soft parts of the insect are digested and elaborated as food for the plant. After digestion and absorption, which may occupy two or three weeks, have been completed, the trap opens and only the chitinous skeleton of the insect remains. If the insect is not caught, the trap opens within an hour or so and is ready for the next trespasser. A single leaf seems to be capable of digesting only a few insects, after which its vigor diminishes; it responds less actively to excitation of the glandular surface and soon dries up or decays. Consult Darwin, *Insectivorous Plants* (New York, 1892).

DIONE, di-ō'nē (Lat., from Gk. Διώνη). A Titan associated with Zeus at Dodona (q.v.) as his wife; and by him the mother of Aphro-

dite, who is therefore sometimes called Dionæa (see *Iliad*, v, 370). John Gay wrote a pastoral drama under this title (1720). Consult Hadzits, "Aphrodite and the Dione Myth," in *American Journal of Philology*, 30 (1909).

DIONNE, de'ōn', NARCISSE EUTROPE (1848–). A Canadian author and librarian. He was born at Saint-Denis de la Boutellerie and was educated at Sainte-Anne's College, the Quebec Grand Seminary, and Levis College. He graduated in medicine at Laval University in 1872 and practiced at Stanfold, P. Q., but later took up journalistic and literary writing. He was editor of *Le Courrier du Canada* and then of *Le Journal de Québec*, and after 1892 he was chief librarian of the Quebec Legislature. He was elected a fellow of the Royal Society of Canada. Among his numerous publications are: *Histoire de l'église de Notre Dame des Victoires* (1888); *Jacques Cartier* (1889); *La vie de C. F. Painchaud* (1894); *Les ecclésiastiques et les royalistes français réfugiés au Canada à l'époque de la révolution, 1791–1802* (1905); *Champlain* (1905); *Chouart et Radisson* (1910); *Gabriel Richard, Sulpicien* (1911); *Une dispute grammaticale en 1842* (1912).

DIONYSIA, di'ō-nish'i-ā. See GREEK FESTIVALS.

DI'ONYSI'ACA (Lat., from Gk. Διονυσιακά, *Dionysiaka*). A long epic in 48 books, by the Greek poet Nonnus, of Panopolis in Egypt, dating probably from the fifth century B.C. It recounts the of Dionysus in the East and is one of the chief sources for the legends concerning the god.

DIONYSIUS, di'ō-nish'i-ūs (Lat., from Gk. Διονύσιος, *Dionysios*), surnamed THRAX ('the Thracian'). A Greek grammarian, native of Alexandria, who taught at Rhodes and at Rome in the first century B.C. His *Art of Grammar* (*Τέχνη Γραμματική*) is the foundation of all subsequent European works on grammar. The best edition is that of Uhlig (Leipzig, 1884). For an excellent account of the work, consult Sandys, *A History of Classical Scholarship*, vol. i (2d ed., Cambridge, 1906). Dionysius wrote much also on Homer.

DIONYSIUS, or DINIZ, de-nēz' (1261–1325). The sixth King of Portugal. He was the son of Alfonso III of Portugal and the grandson of Alfonso X of Castile and was born Oct. 9, 1261. He succeeded his father in 1279 and after some difficulty effected a compromise with the Pope regarding the privileges of the clergy. His brother attempted to supplant him, on the plea that he was illegitimate by birth, but was soon subdued. Later Dionysius' son, jealous of a favorite, raised the standard of rebellion. By the intercession of the Queen mother, Isabel of Aragon (afterward canonized), war was avoided, and the son was allowed to exercise a powerful influence over the policy of the government. The reign of Dionysius was a period of reform. The administration of civil and criminal justice was changed and the power of the great lords curbed. Industry and commerce were fostered, the mines were made a fruitful source of revenue, and fortifications were built in more than 40 places; because of his interest in improving methods of agriculture, he became known as "the farmer king." He was a patron of literature and himself wrote poetry. About 1291 a university was founded at Lisbon, which in 1306 was transferred to Coimbra. The military Order of

Christ. founded in 1318 by Diniz and Pope John XXII, was endowed with the confiscated property of the Templars. Dionysius was one of the most liberal princes of his time, and won the title of the "father of his country." He died Jan. 7, 1325. Consult Schaefer, *Geschichte von Portugal*, vol. i (2d ed., Hamburg, 1874).

DIONYSIUS, EAR OF. The name given, since the sixteenth century, to one of the Lautumiae, or quarries, of Syracuse, known now as the Latomia del Paradiso, a grotto hewn in the rock in the form of the letter S, 210 feet deep, 74 high, and 15-35 wide; it contracts towards the summit. The shape of the grotto is due to the rounding of the adjoining theatre. Since it is related of Dionysius the Elder that he constructed prisons with such acoustic properties that at a given point he could overhear the conversation of the prisoners, this remarkable grotto has, not unnaturally, gained its present name.

DIONYSIUS, SAINT. Pope, 259-268. He was a Greek by birth and must have been among the most distinguished members of the Church in Rome, even before his elevation, as his distinguished namesake of Alexandria addressed to him two letters on different subjects: afterward the teaching of the latter on the Trinity was reviewed by him in a synod held in 262 and was the occasion of a notable letter to the Egyptian churches. He did much to reorganize the church after the severe persecutions to which it had been subject. His day in the calendar is December 26.

DIONYSIUS EXIGUUS (Lat., Dionysius the Little). A learned monk who lived in the fifth and sixth centuries. The epithet of *Exiguus* is merely a term of humility, used by Dionysius himself. Cassiodorus (q.v.), who was his fellow pupil, says that Dionysius was "a Scythian by birth, but wholly Roman in other respects." He made a collection containing (1) the first 50 canons of the Apostles; (2) the canons of 10 councils; (3) 38 decretals of the popes, from 384 to 498. This collection, of which there were two redactions, had great authority in the West. Somewhat changed, it was solemnly promulgated by Charles the Great in 802. (See CANON LAW.) Dionysius completed the paschal cycle and introduced the custom of counting the years from the birth of Christ. (See CHRONOLOGY.) He died before 555. Various works of Dionysius are printed in Migne's *Patrologiae Latinae Cursus Completus*, vol. lxvii. But this, as well as the earlier editions, is uncritical and incomplete. Consult Tardif, *Histoire des sources du droit canonique* (Paris, 1887).

DIONYSIUS OF ALEXANDRIA, SAINT, called the Great (?-265). An early Christian writer. He was born at Alexandria of a noble pagan family, but was an early convert to Christianity and under the influence of Origen became a priest, and head of the famous catechetical school in 231. In 248 he became Bishop of Alexandria, but continued to hold his former position. In the persecution of Decius (250) he was arrested and condemned to death, but was rescued by peasants and remained concealed for a year in the Libyan desert. In 257 he was again exiled, but restored three years later. His day is November 17. Most of his works are lost. Such as remain are in Migne, *Patrol. Graeca*, vol. x; Eng. trans. in *Ante-Nicene Fathers*, vol. vi. Consult: Förster, *De Doctrina*

et Sententiis Dionysii Magni (Berlin, 1865); and for his biography, Dittrich (Freiburg, 1867), Paul Morize (Paris, 1881), and *Letters and Other Remains*, ed. by Feltoe (New York, 1904); Harnack, *Geschichte der altchristlichen Literatur*, vol. i (Leipzig, 1893).

DIONYSIUS OF HALICARNASSUS. A learned critic, antiquarian, and rhetorician. He was the son of one Alexander of Halicarnassus and was born probably about the middle of the first century B.C. He came to Rome at the termination of the civil wars (29 B.C.), and resided there for 22 years, familiarizing himself with the language, literature, and antiquities of the Romans. He taught rhetoric and was intimate with many men of distinction. His death occurred after 7 B.C. Dionysius' most valuable work is unquestionably his *Antiquities of Rome*, although it does not exhibit the finest qualities of his mind. This work treats the history of Rome from the mythical period down to the First Punic War. The author was an admirable rhetorician, but had very little political discrimination, and no perception of the difference between a myth and an historic fact. Yet, inasmuch as this work contains a mine of information about the constitution, religion, history, laws, and private life of the Romans, it will always command the regard of scholars. Of the 20 books we possess only the first nine in a complete form, the tenth and eleventh nearly so; of the rest, only a few fragments survive. Dionysius' work was much used by Appianus (q.v.). The first edition of the Greek original was that by Stephens (Paris, 1546), but a very good Latin version was published as early as 1480. Angelo Mai published (Milan, 1816) a collection of the fragments of the lost books from a manuscript in the library at Milan, the genuineness of which has been doubted. The rhetorical and critical works of Dionysius are of the highest literary merit. These include: *Censura Veterum Scriptorum*; *Ars Rhetorica*; *De Compositione Verborum*; *De Imitatione*; and special treatises *On the Style of Demosthenes* and *On the Character of Thucydides*. All these works are in Greek. The complete works are edited by Usener and Rademacher (Leipzig, 1899); a good edition of the *Antiquities* is that of Jacoby (ib., 1885-91). W. Rhys Roberts has published editions, with translations, notes, glossaries, etc., of *The Three Literary Letters* of Dionysius, two addressed to Ammaeus, one to Pompeius (Cambridge, 1901), and the *De Compositione Verborum*, 'On Literary Composition' (London, 1910): the former work contains valuable historical and literary material. Consult also Bo-

bus *Dionysii Halicarnensis*, in *Leipziger Studien*, vol. xvii (1895); Sandys, *A History of Classical Scholarship*, vol. i (2d ed. Cambridge, 1906).

DIONYSIUS PERIEGETES (Lat., from Gk. Διονύσιος Περιηγητής). A Greek geographer, author of a Greek poem in 1187 excellent hexameters, entitled *Τῆς Γῆς Οἰκουμένης Περιήγησις*, 'A Description of the Habitable World.' The time and place of his birth are not known. Some place him in the time of Hadrian; others in the latter part of the third or the beginning of the fourth century A.D. His work enjoyed a wide popularity in ancient times and was translated into Latin by Rufus Festus Avienus (q.v.) and by Priscianus. A Greek paraphrase and scholia and a valuable commentary upon it by Eustathius (q.v.) are still extant. The best editions of the *Periegesis* are those by Bernhardt

in *Geographi Græci Minores*, vol. i (Leipzig, 1828), and by Müller, in *Geographi Græci Minores*, vol. ii (Paris, 1861). Consult Bunbury, *Ancient Geography*, vol. ii (London, 1879), and Bernays, *Studien zu Dionysius Periegetes* (Heidelberg, 1905).

DIONYSIUS THE AREOPAGITE. A member of the court of Areopagus (q.v.), at Athens, converted to Christianity through the preaching of Paul (Acts xvii. 34). . . . is known about him. Eusebius, on . . . of Dionysius, Bishop of Corinth, about 175 A.D., records that he was the first Bishop of the church of Athens, and a much later historian says he was martyred there in the reign of Domitian.

to still another tradition, perpetuated by Hilduin (814-840), the abbot of Saint-Denis, he was sent by Clement of Rome into Gaul (Paris), where he died a martyr on Montmartre. There is evident confusion between Dionysius and Saint-Denis (q.v.), patron saint of France, who, according to Gregory of Tours, founded the church in Paris in the third century.

In the sixth century we meet with a body of writings which bear the name of Dionysius Areopagita. Ecclesiastical tradition ascribed them to Paul's Athenian convert, but it is certain that they are the work of a Christian Neoplatonist of the sixth century. The first of these works, entitled *The Celestial Hierarchy*, deals with the three triads of orders of angelic beings; the second, *The Ecclesiastical Hierarchy*, with their three triads of earthly counterparts. Heaven and earth are thus woven together into one grand structure of correspondencies, suggesting the later system worked out by Swedenborg (q.v.). Through these graded hierarchies God communicates Himself to man. The treatise on *Divine Names* inquires what the names applied to the Deity in scripture can teach us respecting His nature and attributes. In the *Mystic Theology* the author explains the significance of the system of symbols which he has hitherto employed and sets forth an intuitive mysticism, the soul's rapture to the divine. It is here especially that, through the pseudo-Dionysius, Neoplatonic and Christian mystics are brought into one line of historical development, for it can be shown that our author drew largely from the Neoplatonists Plotinus and Proclus.

The pseudo-Dionysiac writings were probably produced in the East. Syria and Egypt have been conjectured to have been their home. They are first cited at the Council of Constantinople (553). Their influence appears in the system of the great doctor of the Eastern church, John of Damascus. In the West they are not found prior to Gregory the Great (died 604), but throughout the Middle Ages they exerted a vast influence upon the thought of Christian Europe. In the ninth century Hilduin, abbot of Saint-Denis, wrote a life of Dionysius which gained wide currency, and not long afterward, in the reign of Charles the Bald, the learned John Scotus . . . translated his supposed works into . . . this more accessible form they furnished a prolific source of inspiration to the scholastic theologians, especially . . . Saint-Victor and Thomas Aquinas. . . . tine Platonists of the fifteenth century studied them with ardor, as did the English Humanists, Colet and Grocyn. Their influence is plainly traceable in Dante's *Divine Comedy* and even in Milton. Laurentius Valla and Erasmus cast doubt upon the prevalent belief that these writ-

ings were from the pen of the Athenian Dionysius, but their authenticity was stoutly defended by many writers, and the controversy became very vehement. Now, however, both Catholic and Protestant scholars are agreed that their origin is about the close of the fifth century.

The works of pseudo-Dionysius were edited by Corderius and reprinted in Migne, *Patrol. Græc.* vols. iii, iv (Paris, 1857). An edition of the *De Cælesti seu Angelica Hierarchia* appeared at Freiburg, 1902. For an English translation, consult J. Parker, *The Works of Dionysius the Areopagite* (London, 1897); also, in general, the article "Dionysius," in Smith and Wace, *Dictionary of Christian Biography* (ib., 1877-87); and Hugo Koch, *Pseudo-Dionysius Areopagita in seinen Beziehungen zum Neuplatonismus und Mysterienwesen* (Mainz, 1900). For Hilduin's life, identifying him with Saint-Denis, consult Migne, vol. cvi. Consult also Vaughan, *Hours with the Mystics* (London, 1860).

DIONYSIUS THE ELDER (431-367 B.C.), Tyrant of Syracuse. He began life as a clerk in a public office. He fought with distinction against the Carthaginians, with whom the Syracusans had been at war since 410 B.C. After the loss of Agrigentum through the failure of the Syracusan generals to relieve the town, he accused the commanders and secured the appointment of other officers, of whom he was himself one. He soon, however, supplanted his colleagues and made himself tyrant of the city, in 406 B.C. He had already provided himself with a bodyguard of 1000 men, and he now . . . his position by marrying the daughter of Hermocrates, the leader of the aristocratic party. The time from this latter event to 397, when the next war with Carthage began, he employed in strengthening and extending his power in Sicily. In the new war with Carthage he was at first successful in his operations, but when, in 396, fresh troops were sent to the island, he found himself blockaded in Syracuse and in serious danger of being deprived of his power. But, a pestilence breaking out in the Carthaginian fleet, the tyrant seized the opportunity to surprise the enemy's fleet and army. He was shrewd enough, however, not to push his advantage too far and turned his attention next to those Greeks, especially in lower Italy, who were still independent. In 392 he was interrupted in his plans by a renewal of hostilities by the Carthaginians, but this . . . was soon terminated by a peace, in which . . . recognized Dionysius as ruler of a large part of eastern Sicily. He now once more turned to lower Italy, and in 387, after a siege of 11 months, captured Rhegium. Thus the whole southern corner of Italy came under his rule. In 383 and again in 379 he found himself in conflict with the Carthaginians, who on both occasions tried to attack him by way of lower Italy. From this time, till his death in 367, he ruled without opposition. His influence was great throughout the Grecian world. In 373 he assisted the Spartans against the Athenians; in 369 he supported the Thebans, who were then invading the Peloponnesus, and in 368 his troops took part in the Tearless Battle on the side of Sparta. As a ruler, Dionysius was cruel and unscrupulous. He did much, however, for the material prosperity of Syracuse, which under his rule became the most brilliant of Grecian cities. He sent deputies to the Olympic games, and himself contended for the prize of tragedy at Athens,

in 367 the first prize for a tragedy *Ransom of Hector*. He aimed also to have a literary court and attracted thereto at different times the lyric poet Philoxenus (q.v.), the philosopher Aristippus (q.v.), and Plato. Consult: Holm, *Geschichte Siciliens*, vol. ii (Leipzig, 1874); Grote, *History of Greece*, vols. x, xi (London, 1852-53); Bass, *Dionysius I von Syracus* (Vienna, 1881); Freeman, *History of Sicily*, vols. iii, iv (Oxford, 1891-94). See SICILY; SYRACUSE.

DIONYSIUS THE YOUNGER. Tyrant of Syracuse after the death of his father, Dionysius the Elder, in 367 B.C. He began his rule peacefully at the age of 28, but, having been from motives of jealousy neglected by his father, he was entirely unfitted for his position. His kinsman, Dion (q.v.), conceived the idea of improving him by putting him under the instruction of Plato, but the influence of the historian Philistus (q.v.) proved to be stronger than that of Plato; Dion was sent into exile, Plato was dismissed, and Dionysius encouraged to pursue a course of pleasure. Afterward Plato was recalled to Syracuse, with even worse results. In 356 Dion returned to Syracuse at the head of a force of mercenaries, and Dionysius was obliged to leave Sicily. He retired to Locri in Italy, the birthplace of his mother, Doris, and ruled there despotically until 346, when he once more obtained possession of the island at Syracuse. His rule was so oppressive that the Syracusans finally sought aid of Corinth, and Timoleon (q.v.) was sent to their assistance. Dionysius was shut up in the citadel of Syracuse and compelled to surrender, 343. He was taken to Corinth, where he remained till his death.

DIONYSUS. See BACCHUS.

DIONYSUS, THEATRE OF. The oldest known theatre in the world, lying against the slope of the Acropolis at Athens, at the southeastern corner. It has been the scene of excavations by the German Archaeological Institute since 1886, largely under Dörpfeld (q.v.). The results of the researches show, in the opinion of some scholars, that no permanent building for dramatic representations had existed on the spot until about 330 B.C., when Lycurgus built a stone theatre. Others, however, hold that there was a stone auditorium at a much earlier date. Lycurgus' theatre was transformed into a Roman theatre, first in Nero's time, then further in the days of Hadrian. Consult: Dörpfeld-Reisch, *Das griechische Theatre* (Athens, 1896); E. Gardner, *Ancient Athens* (New York, 1902); Haigh, *The Attic Theatre* (3d ed., Oxford, 1907); M. L. D'Ooge, *The Acropolis of Athens* (New York, 1908); Weller, *Athens and its Monuments* (ib., 1913).

DIOON, δι-ὄν. See CYCADACEÆ.

DIOPHANTINE ANALYSIS. That portion of the theory of indeterminate problems which seeks rational and commensurable roots of equations involving the squares and cubes of the unknown quantity. This class of problems was first and chiefly treated by Diophantus (q.v.), whose name the method bears. Although Diophantus gave problems involving the indeterminate linear equations, he was chiefly interested in solving equations of the second degree: e.g., to find two whole numbers, the sum of whose squares is a square; or to find three square numbers in arithmetic progression. The method of Diophantus, being neither concise nor definite, does not admit of a brief exposition.

The following are, however, some of its characteristics: 1. His quantitative symbolism was limited to that of one unknown. 2. His rules of operation are the common axioms of adding to and subtracting from both members of an equation. 3. He showed much adroitness in selecting the unknown; e.g., so as to avoid affected quadratics or complete cubics. 4. He also showed skill in his tentative assumptions, in assigning separately to the unknown quantity preliminary values which satisfy one or two only of the necessary conditions; then, from its failure to satisfy the remaining conditions, he discovered the required number, a method somewhat analogous to the *regula falsi* (q.v.). 5. He used the symbol for the unknown in different senses, which amounted to the same thing as substituting one unknown for a function of another. 6. He made some use of limits: e.g., to find a square between 10 and 11, Diophantus proceeds thus: No square lies between 40 and 44, nor between 90 and 99, but 169 lies between 160 and 176. These numbers being 16 times 10 and 11, respectively, the square between 10 and 11 is $\frac{169}{16}$. 7. He developed the use of synthesis (q.v.). 8. He showed skill in the introduction of arbitrary conditions: e.g., two numbers being sought such that the cube of one is greater by 2 than the square of the other, Diophantus arbitrarily assumes that the numbers are $x + 1$, $x - 1$. The strength of this analysis does not consist in the elegance and definiteness of the method, but in the consummate skill with which Diophantus makes use of the above devices. Diophantus' name is also associated with the following theorem: The sum of the squares of any three integers can never be expressed as the sum of two such squares. Fermat first proved this theorem and added the corollary: It is impossible that any multiple of a prime of the form $4n - 1$, by a number prime to it, can either be a square or the sum of two squares, integral or fractional.

DIOPHANTINE THEOREM. See DIOPHANTINE ANALYSIS.

DIOPHANTUS (Lat., from Gk. Διόφαντος). A Greek mathematician, who lived at Alexandria probably in the second half of the third century. He is called the Father of Algebra. He occupied himself chiefly with a class of problems discussed under DIOPHANTINE ANALYSIS (q.v.). Of his three works, (1) on *arithmetic*, (2) on *polygonal numbers*, (3) the *porisms*, the *Arithmetica* consisted originally of 13 books, only six of which are extant. The polygonal numbers may have been one book of the *Arithmetica*, and the *Porismata*, which is lost, may also have been part of it. The best-known editions of Diophantus' works are those of Bachet de Mézeriac (Paris, 1621); Schultz (Berlin, 1822); and Tannery (Leipzig, 1893-95). Consult: Heath, *Diophantos of Alexandria* (London, 1885; 2d ed., London, 1910); Gow, *History of Greek Mathematics* (Cambridge, 1884); Nesselmann, *Geschichte der Algebra der Griechen* (Berlin, 1842).

DIOPSIDE (Gk. διόψις, *diopsis*, view through, from διὰ, *dia*, through + ὄψις, *opsis*, view). A variety of pyroxene that crystallizes in the monoclinic system and is essentially a calcium magnesium silicate. It is usually white or light gray, yellow, or green in color, although sometimes, owing to the presence of iron, it is dark green and nearly black. Diopside is a common mineral occurring in crystalline limestone and dolomite,

in serpentine or igneous rocks. Transparent, oily, green crystals, especially those from St. Lawrence Co., N. Y., have been found sufficiently large and clear to be cut into gems weighing from 6 to 8 carats each. A variety containing chromium that is deep emerald green in color has been found of sufficient size for small gems.

DIOPTASE. A basic copper silicate crystallizing in hexagonal forms and of a deep blue color and vitreous lustre. It occurs in Hungary, Chile, and at the copper mines of Clifton, Ariz.

DIOPTER, DIOPTRIC SCALE. The unit adopted by ophthalmologists in measuring the strength of lenses used in the correction of defective vision. A concave or convex lens with a focal length of 1 meter is taken as the unit, and the reciprocals of the focal lengths supply the numbers which are assigned to the lenses. Thus a lens with a focal length of .5 meter would be designated as Number 2, and one with a focal length of .1 would be a Number 10. The measures are the same whether the lenses are positive (convex) or negative (concave), but in the former case the + sign is prefixed to the number, while in the latter it is the - sign.

DIOPTOMETER (Lat. *dioptra*, Gk. *διόπτρα* leveling instrument, from *διά*, *dia*, through + *όπτω*, *optō*, visual + *μέτρον*, *metron*, measure). An instrument used by oculists and opticians in measuring directly the curvature and focal length of glasses used to correct defective vision. It is based on the principle that the focal length of lenses of the glass usually employed is very nearly equivalent to one-half the sums of the radii of curvature. This follows from the formula that

$\frac{1}{f} = (\mu - 1) \left(\frac{1}{r} + \frac{1}{s} \right)$, where f is the principal focus, μ is the index of refraction, and r and s are the radii of curvature of the two surfaces. As μ is 1.5, it will be

seen readily how the focal length can be obtained when once the two radii of curvature are known. The dioptrimeter is a simple arrangement of levers by means of which the curvature of any spherical surface is indicated, and the result shown in diopters. If the lens is plane, convex, or concave, the focal length is obtained directly by inspection, but if both surfaces of the lens are curved, the algebraical sum of the two readings must be taken.

DIOPTRICS. That branch of optics which deals with the refraction of light. See **LIGHT**.

DIORITE (from Gk. *διολίττειν*, *diorizein*, to distinguish, from *διά*, *dia*, through + *όρίζω*, *horizein*, to divide, from *ὅρος*, *horos*, boundary). An igneous rock of granitic texture, the essential constituent minerals of which are a lime-soda feldspar and either hornblende or dark mica, or both of these minerals. The average chemical composition of diorite is about as follows: silica, 61 per cent; alumina, 16 per cent; ferric oxide, 3 per cent; ferrous oxide, 5 per cent; magnesia, 4 per cent; lime, 6 per cent; soda, 3 per cent; potash, 2 per cent. Many rocks formerly classified as diorites are now by many writers separated because of peculiarities of texture and of manner of occurrence; e.g., kersantite, aphanite, aphanite, etc. In addition to lime-soda feldspar, hornblende, or mica, diorites may contain quartz, alkali feldspar, or augite, and other minerals in smaller quantities. According to the presence or absence of quartz, diorites are classified as quartz diorites or diorites proper. Each of

these groups is subdivided into mica diorites, hornblende diorites, or augite diorites, according as mica, hornblende, or augite predominates among the darker minerals. Peculiarities of texture alone serve to distinguish quartz diorites from dacites (q.v.), and diorites from andesites (q.v.), the composition being essentially the same. Chemically diorites differ from granites chiefly in containing less silica and potash and more lime, magnesia, and iron. Mineralogically they are distinguished by the greater abundance of lime-soda feldspar and by the darker color, due to the greater abundance of mica and hornblende. Diorite is often quarried for use as a building stone.

DIOSCOREA/CEÆ (Neo-Lat. nom. pl., named after the Greek physician and botanist Dioscorides). A family of monocotyledonous twining herbs and shrubs, with large tubers or rhizomes, of which the genus *Dioscorea* (see **YAM**) is the type. Some species bear aerial tubers in the axils of the leaves, as the air potato, one of the species of yams. There are about 9 genera and 200 known species. The most important plants of the order are the different species of *Dioscorea*, or yam, a number of which occur in the United States, *Dioscorea villosa* being the most common. Black bryony (*Tamus communis*) is a representative species in the European flora. *Dioscorea*, or *Testudinaria elephantipes*, a South African species, sometimes called elephant's foot, and Hottentot bread (q.v.), has a large, fleshy rhizome, with a rough cracked bark, which is used as food by the Hottentots in times of scarcity. The chief genera are *Dioscorea*, *Tamus*, and *Testudinaria*.

DIOSCORIDES (Lat., from Gk. *Διοσκορίδης*, *Dioskoridēs*), **PEDANIUS**. A Greek physician. He was a native of Anazarbus, in Cilicia, and flourished in the time of Nero. He accompanied the Roman armies as physician through many countries and collected a great store of information on plants. In his great work, *De Materia Medica*, in five books, he treats of all the medicinal substances then known and their properties. Two spurious works, *Alepharmaca* and *Theriaca*, assigned to him by Photius, are by a later Dioscorides of Alexandria. During 15 centuries Dioscorides maintained undisputed authority in botany and in materia medica, an authority which he still holds among the Turks and the Moors. The best edition is by Sprengel (2 vols., Leipzig, 1829); it contains a Latin translation and a commentary. The *De Materia Medica* was translated into Latin at an early date and later into all the vulgar tongues of western Europe. There is also an Arabic translation.

DIOSCURIA. See **CASTOR** and **POLLUX**.

DIOSCURIAS. See **COLCHIS** (end).

DIOSPOLIS (Lat., from Gk. *Διόσπολις*, city of Zeus). A name applied to several cities of antiquity. For Diospolis in Palestine, see **LYDDA**; and for those of Egypt, see **THEBES**.

DIOSPYROS. See **EBONY**; **PERSIMMON**.

DIOŚY, **ARTHUR** (1856-). An English Orientalist. He was born in London, the son of Martin Diośy (1818-92), secretary to Louis Kossuth. He was educated in England and Germany and early became interested in the Far East, working for the Anglo-Japanese alliance and founding (1891) the London Japan Society. He edited two volumes of the Japan Society's *Transactions* and *Proceedings*, wrote and lectured on Japan, China, and the East in

general, and published *The New Far East* (1898; 8th ed., 1904).

DIOTIMA, di'ô-tî'mâ (Lat., from Gk. Διοτίμα). The Mantinean priestess in Plato's *Symposium*, who describes in figurative language the doctrine of Platonic love.

DIOXYGEN. See HYDROGEN DIOXIDE.

DIP (AS. *dyppan*, *dippan*, to dip, Goth. *daupjan*, OHG. *toufen*, Ger. *taufen*, to baptize, from AS. *deop*, Icel. *djúpr*, Goth. *diups*, OHG. *tiof*, Ger. *tief*, Eng. *deep*). A term used by geologists to denote the inclination of rocks to a horizontal plane. Stratified and schistose rocks are seldom horizontal, and their dip may vary from a slight inclination to absolute verticality. The amount of dip (expressed in degrees) is measured by a clinometer (q.v.). When strata have been upraised into dome-shaped structures which have an outward slope in every direction from a central point, the dip is called "quâ-quâ-versal."

DIP, MAGNETIC. See INCLINATION, MAGNETIC.

DIPAVANSA, dē'pā-vān'sā (Pāli, *dīpa*, island + *vamsa*, lineage). The title given to the oldest chronicle history of the island of Ceylon. It is written in the Pāli language and dates from the fourth century of our era. An account is given in this old record of Buddha and the history of Buddhism in Ceylon down to the year 302 A.D. Like the other Ceylonese chronicle, the *Mahāvansa* (q.v.), to which it is akin, the *Dipavansa* is based on an older source. A record is preserved in the scholiast on the *Mahāvansa* that King Dhātusena (459-477 A.D.) caused the *Dipavansa* to be publicly read at an annual festival held in honor of Mahinda, the apostle who introduced Buddhism into Ceylon. The text of the *Dipavansa* has been edited and translated by Oldenberg, *The Dipavamsa; An Ancient Buddhist Historical Record* (London, 1879); Gieger, *Dipavamsa und Mahāvamsa* (Erlangen, 1901; Leipzig, 1905).

DIP CIRCLE. If a magnetic needle be supported so as to be free to move in a vertical plane, at most places on the earth's surface, it does not rest in a horizontal position, but has a certain amount of inclination. If the vertical plane in which the needle moves contains the magnetic meridian of the place, the angle between the needle and the horizontal line is called the dip, or inclination, of the needle. The dip of the magnetic needle at any place can be ascertained with exactness by means of the dip circle. It consists of a graduated circle fixed vertically in a frame, which can be revolved about a vertical axis on a horizontal graduated circle. This last is supported on a tripod, or may be arranged on a gimbal stand for use on ship-board. At the centre of the vertical circle there are two knife-edges of agate, supported by the frame and parallel to the plane of the circle. The needle rests on these knife-edges by means of two fine polished cylinders of steel, which are placed accurately at the centre of the needle and project at right angles from it, or it may be mounted on jeweled bearings. The angle made by the needle can be read on the vertical divided circle by means of microscopes. The needle is carefully balanced so that before it is magnetized it will remain indifferently in any position; after magnetization, therefore, the dip which it shows is wholly due to the magnetic influence of the earth.

In order to understand how an observation is made with the dipping needle, we must regard

the directing force of the earth's magnetism exerted upon the poles of the needle in any vertical plane in which it may happen to be, as resolved into two forces—one acting at right angles to the plane, and the other acting in the plane. There being a corresponding but opposite force at each pole, we have thus two statical couples acting on the needle—one tending to turn it at right angles to the plane in which it moves, and the other tending to bring it round to a position in the plane such that the needle and the forces of the couple may be in a line. In the dipping needle the mode of support completely neutralizes the first of the couples; and the position that the needle takes in any plane is due wholly to the second. When the plane of the needle is at right angles to the magnetic meridian, the forces of this latter couple act vertically and bring the needle to a vertical position. This, then, gives us the means of determining the magnetic meridian, for we have only to bring the vertical circle round till the needle stands at 90° to put it in a plane at right angles to that meridian; and then by moving the vernier on the horizontal circle over 90°, we place the upper circle and needle in the plane of the magnetic meridian. The dipping needle may thus serve to determine approximately the magnetic declination. In bringing the needle round from the plane at right angles to the magnetic meridian the dip is less and less, till it becomes least in the plane of that meridian. We might thus also find the magnetic meridian, for it is that plane in which the dip of the needle is least. When the needle is in the plane of the magnetic meridian, the couple which acts in other vertical planes at right angles to them disappears, and the whole force of the terrestrial magnetism

DIP CIRCLE — KEW PATTERN.

acts at each pole of the needle, forming a couple which swings the needle round till it stands in a line with itself. The degree on the circle then pointed to by the needle is the dip at the place of observation. The method of observation is designed so as to eliminate all outstanding errors due, for example, to mechanical imper-

fections of construction, and to imperfect adjustments. The position of the needle when the dip is read off is manifestly the same that a needle suspended in air, if that were possible, and free to move in any way, would finally assume. In resolving, therefore, the total directive force of the earth as we have done above, we must keep in mind that it always acts parallel to the direction of the dipping needle.

The direction and intensity of the earth's magnetism may be roughly represented by supposing that there is a magnet at the centre of the earth whose length is very small in comparison with the earth's diameter, and which makes an angle of about 11° with the earth's axis of rotation. However, owing to the complex magnetization of the earth, a line . . . the earth's magnetic poles does not pass through the earth's centre but about 750 miles away from it. The magnetic equator is defined as the line along which the dip is everywhere zero. As we proceed from the magnetic equator towards the magnetic poles, the amount of dip increases from zero to 90° , and there is also a considerable change of dip from time to time at any one place. The dip in Paris was 75° when it was first observed in 1671, and from this it had fallen to $65^\circ 18'$ in 1885, and at the present time is about 65° . See TERRESTRIAL MAGNETISM; INCLINATION.

DI-PHENYL-AMINE DERIVATIVES.
See COAL-TAR COLORS.

DIPHILUS (Lat., from Gk. Διφίλος), of Sinope. An Attic poet, of the New Comedy, who flourished about 300 B.C.; a contemporary of Menander (q.v.). He is supposed to have written about 100 comedies, of which the titles and fragments of about 50 are still extant. He frequently took his subjects from common life and mythology, so that, though in point of time they belonged to the New Comedy, his works seem to have had more of the character of the Middle Period. The *Casina*, *Commoventes*, *Vidularia*, and *Rudens* of Plautus are modeled on plays of Diphilus, and Terence borrowed from his *Συναποθήσκοντες*, in the *Adelphi*. The extant fragments of his works are collected in Meineke, *Fragmenta Comicorum Græcorum*, vols. i and iv (Berlin, 1839-57); and in Kock, *Comicorum Atticorum Fragmenta*, vol. ii (Leipzig, 1884). These fragments, and the judgments passed on Diphilus in antiquity, have led to the belief that he was one of the most gifted poets of his age.

DIPHTHERIA, or **DIPHTHERITIS** (Neo-Lat., from Gk. διφθέρα, *diphthera*, leather). An acute infectious and very . . . disease, caused by the Klebs-Löffler bacillus. (See PLATE OF DISEASE GERMS.) It is characterized by an inflamed throat in which a false membrane appears on the mucous membrane in patches, generally first on the tonsils, and then extending down to the larynx, up into the nasal passages, and into the mouth. It also appears on other mucous surfaces and upon any ulcer that may exist elsewhere. The false membrane is formed of lymph, which exudes upon the surface, together with mucus, pus, and the bacilli named. The mucous membrane is congested and swollen, and if the diphtheritic exudation be rubbed off, bleeding occurs, and the spot is very tender. The patient is very weak and depressed, suffers from fever, thirst, nervousness, insomnia, and loss of appetite. The throat is painful and the lymphatic glands in the neighborhood be-

come swollen and tender. Meningitis and Bright's disease frequently complicate diphtheria, and paralysis is a frequent occurrence during or a few weeks after the attack. The diagnosis of the disease is not always easy, and suspicious cases of tonsilitis are quarantined, as are all cases of undoubted diphtheria, till cultures made with mucus from the neighborhood of the tonsils have been examined microscopically for the bacilli of the disease. Besides separating the patient from the rest of the family by removing him to an upper room, from which carpets, upholstered furniture, and all cloth hangings have been removed, provision must be made for the nurse, so that she may change her clothing and disinfect her face, hair, and hands, before passing through the house for her daily airing out of doors. Quinine, mercury, iron, chlorate of potash, and alcoholic stimulants are used by physicians. The hypodermic injection of diphtheria antitoxin, introduced in 1894, gives by far the best results, as stated hereafter. Where antitoxin can be had, other treatment is merely symptomatic.

History. It is believed that an epidemic disease which existed anterior to Hippocrates (c.460-360 B.C.) was diphtheria. The malady is described by Aretæus of Cappadocia (c.100 A.D.) under the names *Ulcus Syriacum* and *Malum Egypticum*. Perhaps the earliest modern treatise upon the disease was that by Hecker, descriptive of the epidemic which prevailed in Holland in 1337. In 1517 diphtheria of a malignant type raged in Switzerland, along the Rhine, and in the Netherlands; in 1557 it was epidemic in France, Germany, Holland, and Spain. In 1659 it had reached the New England States in America. In 1765 a Scotch physician, Francis Home, endeavored to establish the fact that the . . . disease now called diphtheria was different from croup. In 1771 Dr. Samuel Bard, of New York, opposed Home, in a controversy, publishing very important and accurate observations regarding the disease. The term "putrid sore throat," given to the disease by Dr. John Fothergill, of London, in 1745, remained the accepted name in English-speaking countries until, in 1821, Bretonneau, of Paris, published his admirable and extensive observations upon the disease and gave it its present name. Little advance was made in the knowledge of diphtheria after Bretonneau's treatises were put forth until the microorganism of the disease was isolated.

Mortality. The control of diphtheria, which has been epidemic in America since 1857, is . . . the early treatment of the disease . . . antitoxin, together with systematic isolation of cases. While occasional clinicians of experience and ability are found who actively antagonize the theory of, and deny the good results from, the use of antitoxin, the great and overwhelming mass of evidence in its favor continues to increase year by year. The diphtheria committee of the Clinical Society of London published in its report for 1898 the following results of inquiry into 633 . . . cases of diphtheria: The total mortality in . . . cases was 19.5 per cent, as opposed to 29.6 per cent in the nonantitoxin control series, compiled before the introduction of antitoxin. In the tracheotomy cases the mortality amounted to 36 per cent, as opposed to 71.6 per cent in the non-antitoxin series. Buchwald, of Munich, reported 57.72 per cent of deaths in cases treated without

antitoxin, 28.93 per cent of those treated with antitoxin. Krönlein, of Zurich, reported to the Congress of German Surgeons in 1898 upon 1773 cases of diphtheria observed in the clinical hospitals of the University from 1881 to 1897. The mortality in the preantitoxin period was 39.9 per cent, against 12.5 per cent in the antitoxin period. In the operation cases (including both tracheotomy and intubation cases), the mortality was 66.1 per cent under the old régime, and 35.6 per cent with antitoxin. In the cases upon which no operation was done the mortality in the preantitoxin period was 14.2 per cent, against 5.6 per cent under antitoxin. The mortality at the South Department, Boston, a large infectious hospital, from 1888 to 1894, the year of the introduction of antitoxin, was 43.2 per cent. From 1895 to 1904 inclusive, it was 11.48 per cent. For the year 1912 it was 7.6 per cent, including laryngeal and moribund cases. The greatest reduction was in the very severe cases where massive doses of antitoxin were administered. Both nasal and laryngeal diphtheria require large doses of antitoxin. Dr. H. M. Biggs concludes, from extensive experience and many researches made as pathologist of the Health Department of New York City, that, "since the introduction of antitoxin treatment, the mortality of diphtheria is reduced one-half; its course is shorter and milder; an injection made within the first two days of the disease reduces the mortality to 5 per cent, and the earlier the injection is made the better is the result. Small quantities of concentrated serum are tolerated by very young infants. If antitoxin is not a specific, it is certainly the best remedy in our possession against diphtheria. The genuine (i.e., un-complicated bacillary) cases are more amenable to its favorable influence than mixed infections. It has no secondary effects on the heart, kidneys, or nerves. Heart failure and paralysis, whenever observed, are caused by diphtheria, not by antitoxin."

Carriers. Diphtheria is not an air- or dust-borne disease, but is spread by direct contact with the infected secretions of the nose and throat. Attendants upon those sick with the malady should avoid letting the patient cough in their faces, should disinfect all fresh secretions, and should be "immunized" by small doses of antitoxin. The greatest problem is the carrier—an individual who has clinically recovered, but who continues to harbor the bacilli, often of a virulent character, in the nasal passages or throat. Antitoxin has very little effect on such cases, and cultures taken from them continue to prove "positive" for Various expedients have been tried to sterilize carriers. Painting the tonsils with iodine preparations, spraying with staphylococcus cultures to "override" the Klebs-Löffler organism, the injection of vaccines, and even the removal of the offending tissues (such as tonsils and adenoids) have been practiced with greater or less success. It has been shown that patients with abnormal upper-air passages are much more likely to harbor pathogenic germs than those possessing normal noses and throats.

Bacteriology and Pathology. The bacillus which causes diphtheria was discovered in 1883 by Klebs, and in 1884 Löffler published the results of his careful study of the bacillus. Roux and Yersin added proof to the dependence of diphtheria upon this bacillus, and the names of the first discoverers have been given to the

causative The bacillus is from 2.5 to 3 micromillimeters long and about one-fifth as wide. It varies in shape, being straight or slightly curved, with rounded, clubbed, or, more rarely, pointed extremities. It is aerobic, nonmotile, and nonliquefying, and grows best in a slightly alkaline medium. One of its most marked peculiarities is that, when treated with Löffler's alkaline methylene-blue solution, it takes an irregular stain, being darker in some parts than in others. This peculiarity is extremely valuable in identifying the organism. Artificially the bacillus may be cultivated on bouillon, agar, or blood serum, but it grows most rapidly and luxuriantly on glucose broth serum (Löffler's blood-serum mixture) at about body heat. Advantage is taken of this in determining its presence in doubtful cases. Thus, if a scraping from the membrane be rubbed over the surface with blood serum, and the tube containing the same be placed in an incubator for from 12 to 16 hours, the Löffler bacillus, if present, so outstrips most other bacilli in growth that a specimen examined with the microscope shows an almost pure culture of diphtheria bacilli. The bacillus does not develop spores (see BACTERIA), can live for months in the dried condition, but is killed by exposure for 10 minutes to 58° C., moist heat. Various other bacteria are often associated with the Löffler bacillus in diphtheria. Of these, the most common and most important is the *Streptococcus pyogenes*. This organism is probably responsible for the suppuration of the glands, for the broncho-pneumonia, and the general infection, which sometimes occur during the course of a diphtheria.

To Weigert, Wagner, and Oertel we are indebted for much of our knowledge of the minute which take place in the formation of the membranes. The diphtheria bacilli or their poisons first induce necrosis of the more superficial cells. This is followed by a more extensive necrosis, with exudation, the whole forming the well-known false membrane. This membrane is most common on the mucous membrane of the tonsils and adjacent parts of the pharynx, but may extend to or involve any portion of the mucous membrane of the throat, mouth, or nose. Among the most fatal forms of diphtheria are those in which extensive membranous formation takes place in the nose or in the larynx, the latter sometimes called "membranous croup." (See CROUP.) Diphtheritic membranes are occasionally found on the conjunctiva, in the external auditory canal, the mucous membrane of the anus and genitals, and on wounds of the skin. Of lesions in other organs, broncho-pneumonia is not uncommon, and some cases are accompanied by acute parenchymatous nephritis. Of later effects, the most common and important is paralysis, a lesion of the nature of a multiple neuritis, due to the poison of the disease. The changes in the nerves are of a degenerative character, and quite similar to those found in neuritis (q.v.) from alcohol or other poisons.

Toxin and Antitoxin. The has been isolated by Roux, Fraenkel, and by filtration of cultures of the living porous porcelain. It appears to be analogous to the poisons of certain venomous serpents. Behring (q.v.) announced his discovery of diphtheria antitoxin in 1890. He, Fraenkel, Wernicke, Aronson, Roux,

and others succeeded in rendering animals immune to diphtheria by the use of inoculations of virulent or somewhat attenuated cultures of diphtheria toxin. Behring, in conjunction with others, showed that the blood of immune animals contains a substance which neutralizes the diphtheria toxin. The blood serum of persons who have recovered from diphtheria has also been found to possess this protective property, which it acquires about a week after the beginning of the disease and loses again in a few months. To lengthen the term of immunity, Behring, in 1913, introduced a vaccine consisting of a mixture of diphtheria toxin and antitoxin. To obtain antitoxin for therapeutic purposes, strong toxin obtained from virulent cultures of the Klebs-Löffler bacillus is injected into the bodies of young, healthy horses. At the end of two months, during which time increasing doses of the toxin have been given, blood is drawn from the horses and tested for antitoxin. That having sufficiently strong antitoxin is retained and the process of inoculating and of . . . serum is repeated for years, all . . . months of each year as an interval of freedom from inoculations. The antitoxin serum is used hypodermically as soon as a diagnosis of diphtheria has been made, in dosage of from 600 to 2000 units, a unit being equivalent to 1 cubic centimeter of "normal serum"; i.e., of blood serum of an immunized animal, which was made so efficacious that 0.1 cubic centimeter antagonizes 10 times the minimum of diphtheria poison fatal to a guinea pig weighing 300 grams, or about 10 ounces. Consult Löffler (et al.), *The . . . of Diphtheria* (C. . . 1913), . . . *Diphtheria in Practice* (London, 1908). See ANTITOXIN; BACTERIA; IMMUNITY; SERUM THERAPY, and the various authorities referred to thereunder.

DIPHTHERIA (IN FOWLS). See ROUP.

DIPHTHERIA (IN PIGS). See SWINE PLAGUE.

DIPH'THONG (Lat. *diphthongus*, Gk. διφθόγγος, *diphthongos*, diphthong, from δι-, *di-*, double + φθόγγος, *phthongos*, sound, from φθέγγεσθαι, *phthengesthai*, to utter). A term used to denote two vowel sounds following one another so closely as to form but one syllable, as in *out*. In this combination the sound is really composed of an *a* as heard in *father* and a *u* as heard in *put*. The . . . ish has little or no relation . . . in this matter. In many syllables written with two vowels, only one sound is heard, as in *bread*. This is often called an "imp . . . contradistinction with the . . . as indicated in the word *out*. The . . . letters, again, often represent a . . . sound; thus, the long sound of *i*, as it is called, is really composed of the sound of *a* as heard in *father* and that of *e* in *me*; and *tune* is pronounced as if written *teun*, or rather *tyun*. In such words as *bread*, *field*, the vowels, which are now monophthongs, were at one time real diphthongs and are still so pronounced in some parts of England; on the other hand, many diphthongs in modern English are developed from original simple vowel sounds, . . . the *ou* in *mouse* is derived: . . . old English *mūs*.

DIP'LOCOC'US. See BACTERIA.

DIPLOD'OCUS (Neo-Lat., from Gk. διπλός, *diploos*, double + δόκος, *dokos*, beam). A gigantic fossil reptile of the order Dinosauria, sub-

order Sauropoda, found in the Jurassic rocks of western North America. Its body was long and low, its head remarkably small, its neck very long, trunk short and deep, and the tail was very long and quite thick at the base. The legs were strongly built and of almost equal length, indicating quadrupedal locomotion, and the feet were armed with heavy claws. The skull was high and laterally compressed posteriorly, with a long sloping face, and with large orbits situated far back on the sides. The jaws had weak, slender, spreading teeth only in their anterior portions, all the premolars and molars being absent. The vertebrae of *Diplodocus* are of great interest because of the elaborate systems of plates and buttresses that give support to the vertebral processes and thus lend great strength without much increase of weight. The animal appears to have been herbivorous and was probably aquatic, living in the extensive marshes and swamps of the Jurassic seas and lowlands that probably resembled those of the modern Amazon and Congo basins. Some figures, based upon the skeleton mounted in the Carnegie Museum at . . . express more clearly the immense . . . of this ancient reptile. The total length, from tip of nose to tip of tail, was about 60 feet, and its height was nearly 12 feet. The head was 2 feet long, only one-thirtieth of the length of the body, and the neck 20 feet in length. The trunk, from the point of the shoulder blade to the middle of the sacrum, measured 13 feet and had a depth of 7 to 8 feet, and the tail was at least 25 feet long. The animal is estimated to have weighed, when alive, about 20 tons and to have required a daily meal of at least 500 pounds of vegetable food such as the twigs, leaves, and succulent stems of plants that grew in the waters of its habitat. Consult Hatcher, "Diplodocus, Marsh: Its Osteology, Taxonomy, and Probable Habits," *Memoirs of the Carnegie Museum*, vol. i, No. 1 (Pittsburg, 1901); Lucas, *Animals of the Past* (New York, 1901). See DINOSAURIA.

DIPLODUS. See PLEURACANTHUS.

DIPLOGRAP'TUS (Neo-Lat., from Gk. διπλός, *diploos*, double + γράφω, *grapho*, I write). A genus of axonophorous graptolites with component bushlike colonies, the stipes of which consist of double rows of single tubular cells. The genus contains about 100 species, among them the most common graptolites of the Ordovician in Europe, America, and Australia. The best-known species are *Diplograptus foliaceus* and *Diplograptus quadrimucronatus*; the latter of world-wide distribution. See GRAPTOLITE.

DIPLO'MA (Lat., from Gk. δίπλωμα, folded paper, letter of recommendation, from διπλός, *diploos*, double). A term used by the ancients especially to indicate letters of license received from the government. It originated in the custom of writing such documents on two tablets of wax which were doubled or on writing material which was folded. Subsequently the term was applied to all old Imperial and ecclesiastical acts and grants, public treaties, deeds, letters, wills, and all similar instruments that were drawn up in a formal manner and marked with a seal or other peculiarities for identification. The term is now restricted, for the most part, to instruments given by universities, colleges, and other learned societies in proof of the holder's having attained a certain degree, or to the licenses held by professional persons as an essential qualification to the practice of their art. While the old

legal significance of such diplomas has largely lost its force, they are yet required by the public as a protection from imposture and as an indication of some qualification in the art professed. In the United States there is a decided tendency towards bringing all such diploma-conferring bodies under the supervision and control of the State, thus putting them upon much the same plane that they occupy in continental Europe. See CHARTER; COLLEGES, AMERICAN; DEGREE; PALEOGRAPHY; UNIVERSITY.

DIPLOMACY. In the wider sense, the art or science of foreign politics. The term is, however, more commonly employed in the more restricted meaning of the art of managing the intercourse and adjusting the relations of states to one another by negotiation. Used in this sense, the word is of modern origin, dating back only to the latter part of the eighteenth century. The art and the processes connoted by the term, however, are as old as international relations and cover the whole field of such relations, whether strictly political or not. The principal objects of diplomacy have always been the same—to preserve the independence and safeguard the security of the state, or to secure some coveted political advantage over other states. Subsidiary to these principal objects have been the more immediate purposes of preserving certain political arrangements—such as the European "balance of power"—intended to prevent the aggrandizement of certain states at the expense of others, the prevention of general wars, and the securing of commercial advantages to the subjects of trading nations. Under settled political conditions, such as now exist in Europe and in North America, the commercial purposes of diplomacy tend to become more prominent than those of a purely political character, though the latter never lose their supreme importance and are never far in the background of international intercourse.

The methods of diplomatic action vary according to the magnitude of the interests involved and the nature of the emergency which calls them into play. For the settlement of questions vitally affecting several states, or such as involve the peace of a continent, or the general policy of the great powers of Christendom, a general congress or international conference may be summoned. Of this character was the Congress of Westphalia, held in 1648 to settle the issues involved in the Thirty Years' War; the Congress of Vienna (1814-15), by which the problems arising out of the Napoleonic wars were adjusted; The Hague Conferences (1899, 1907), for the promotion of the peaceful settlement of international differences among all civilized states; and the Conference of Algieras (1906), for the settling of relations between European powers and Morocco.

Questions of less general importance, arising among two or more states, are more frequently settled by formal treaties or by arbitration by the regular diplomatic agents of the states affected, though these may also be considered and the conflicting claims of the parties adjusted by joint commissions appointed for the purpose. Where these claims cannot be so adjusted by negotiation, resort may be had to a permanent tribunal of arbitration, like that established as the result of the first Hague Conference above referred to, or to arbitrators agreed upon by the parties to the controversy. Matters of less importance, not requiring formal

adjudication or the solemn sanction of a treaty, are commonly dealt with in informal conferences between the foreign offices of the states concerned, and these result in friendly understandings as to the policy to be pursued by them.

The management of the foreign intercourse of a nation is one of the chief functions of the executive head of the state. Formerly it was largely performed by the ruler in person, but it has in modern times passed into the hands of a class of officials known as diplomatic agents, though the most important of these, as ambassadors, are invested with an extraordinary degree of dignity, from the fact that they are supposed to represent the person of the sovereign, and not merely the foreign office of the state by which they are accredited. Under modern conditions the usual instruments of diplomacy are: (1) the principal secretaries of state for foreign affairs; (2) regular diplomatic agents of various grades, ranging from ambassadors to *chargés d'affaires*; (3) occasional embassies or agents of diplomatic intercourse appointed for the accomplishment of a particular purpose. See DIPLOMATIC AGENTS.

Prior to the fifteenth century diplomatic intercourse was conducted almost entirely by ambassadors and other agents of the last-named class, and was as ineffective as its irregularity and lack of knowledge would lead us to expect. But with the establishment of resident legations in that century the practice of diplomacy was raised to a fine art, which rapidly assumed commanding importance in European politics. At a period when international relations were based on personal and dynastic interests, and when statecraft was another name for intrigue, the rôle of the ambassador was second in importance only to that of the sovereign. Success in diplomacy turned largely upon the personal qualities of the ambassador, upon smooth and engaging manners, cunning and astuteness, and was thus a matter of personal influence. Being beyond the reach of instructions, he occupied a position of great independence and power. There was no diplomatic profession, but the great posts in the service were sought after by the greatest persons in church and state. The institution by all the Great Powers of a trained diplomatic service in the last century, and the astonishing improvement in methods of communication, especially in the use of the telegraph, have greatly impaired the power and importance of ambassadors and have tended more and more to reduce them to the position of mere intermediaries, acting under instructions from the governments which they represent.

It may be doubted whether diplomacy can fairly be held responsible for the dishonorable methods with which it has come to be associated. If it has at times been characterized by intrigue and deception, by the absence of large views and generous motives, by selfishness, and a disposition to sacrifice the interests of the weaker to the stronger, it has in these respects only too accurately reflected the statesmanship of its time. And that statesmanship was for centuries based on the perfectly just supposition that "Europe was always in a state of war, overt or latent." The gradual substitution of national for personal and dynastic interests, which the last century has witnessed, has at once given a more pacific character to international relations and a more straightforward and business-like tone to our diplomacy.

Not that suspicion has entirely disappeared from the one, or deception from the other, but they have become the exception and not the rule.

The international relations of states with which diplomacy has to do are only those of a pacific character. With the outbreak of war diplomatic relations come to an end. The suspension of diplomatic intercourse is usually a preliminary to a declaration of war, though it is sometimes employed as a mild means of coercion of a weak state by a more powerful one. In such a case it may be regarded as a strong expression of displeasure, which may, if reparation be unduly delayed, result in the use of force.

The usage of the last 300 years has resulted in the general adoption of French as the language of diplomatic intercourse in Europe. The recent tendency has been to confine this to oral intercourse, written instructions and other diplomatic dispatches being usually couched in the language of the government employing and receiving them.

The history of diplomacy is one of the most interesting and important chapters in the political history of nations. Its sources are to be found in treaties, in the correspondence of ministers of state and ambassadors, contained in the published and secret archives of states, and in the diaries and private correspondence of public officials and courtiers. For a further discussion, see *INTERNATIONAL LAW*, and the authorities there referred to; also Moore, *A Hundred Years of American Diplomacy* (New York, 1900); id., *History and Digest of International Arbitrations* (New York, 1905); id., *The Old Diplomacy and the New* (New York, 1905); id., *American Diplomacy* (New York, 1905); Hill, *History of Diplomacy in the International Development of Europe* (6 vols., ib., 1905-06); Foster, *Practice of Diplomacy as Illustrated in the Foreign Relations of the United States* (Boston, 1906); Paullin, *Diplomatic Negotiations of American Naval Officers, 1778-1883* (Baltimore, 1912).

DIPLOMACY. A play adapted from Sardou's *Dora*, by Bolton and Savile Rowe, and produced in 1878.

DIPLOMATIC AGENTS. In the widest sense, all the officers to whom the intercourse of the state with foreign powers is committed. As thus employed, the expression would include the Foreign Minister, or Secretary of State for Foreign Affairs, and, in the United States, the Senate in the exercise of its constitutional function of approving treaties with foreign states, as well as the regular and occasional representatives of the government abroad. More properly, however, it has reference only to the latter class of officials, who, under instructions from the home government, carry on its intercourse with the Powers to which they are accredited. Attention has been called in the article on *DIPLOMACY* to the fact that for many centuries the diplomatic intercourse of states was carried on by occasional embassies, appointed for a particular purpose, and that it was not until the fifteenth century that permanent and continuous diplomatic relations were instituted by the establishment of resident embassies. By far the greater part of the international intercourse of the modern world is conducted through these regular diplomatic channels, though occasional embassies are still employed for special occasions, principally of a ceremonial character, and the Foreign

Office, or Department of State, of one government may, on occasion, communicate its views directly, by circular or otherwise, to the corresponding office of foreign states.

The transformation of diplomacy in the last century, from the art of applying personal influence in the management of men to the more prosaic and business-like managing the business of the state with foreign nations, has necessitated a corresponding change in the organization and character of the diplomatic service. The personal qualities of shrewdness, a talent for intrigue, and smoothness of address, on which the old diplomacy was based, declined in importance, and made way for the knowledge of international law, of history, of the laws and conditions of trade, of men and affairs, which the new diplomacy required. Accordingly the management of diplomatic intercourse has in Europe generally passed from the men of exceptional gifts or exceptional influence, selected at random for the service, to a professional class of trained diplomatic servants. The comparative isolation of the United States hitherto, and the simplicity of her foreign relations, have delayed the adoption of this reform in her diplomatic service, but the new conditions resulting from the war with Spain and her recent extraordinary commercial expansion indicate that a similar change in the character and organization of her diplomatic service cannot be much longer delayed.

Formerly the term "ambassador" was applied to all accredited diplomatic agents, and it is sometimes still employed, though with "minister," as a general term to describe such agents of whatever rank. But the title is now strictly appropriate for only one, and that the highest, class of diplomatic representatives. The process of classification began before the close of the seventeenth century, but did not receive international recognition until the beginning of the last century. In 1815 the eight principal Powers represented at the Congress of Vienna agreed upon a gradation of diplomatic agents, who were thenceforth to rank as follows: (1) ambassadors, legates, and papal nuncios; (2) envoys, ministers, and others accredited to the sovereign; (3) *chargés d'affaires* accredited to the Department of Foreign Affairs. At the Congress of Aix-la-Chapelle a further distinction was made between ministers plenipotentiary, who were accorded the second place, and ministers resident, who became "an intermediate class between ministers of the second order and *chargés d'affaires*." As the rank of a foreign minister has never to do with his power or with the influence afforded him for transacting diplomatic business or with the immunities enjoyed by him, but is a mere matter of precedence and the ceremony of courts, the United States long refused to recognize the classification of the European Powers and accredited all of its principal diplomatic agents as ministers plenipotentiary, i.e., ministers of full power and authority. In 1893, however, the President was authorized by Act of Congress to appoint ambassadors of full rank and of equal grade and dignity with those which should be accredited by foreign Powers to this country. In accordance with this act the United States is now represented by ambassadors at the courts of Great Britain, Germany, Italy, Austria, Prussia, Russia, Japan, Spain, and the republics of France, Mexico, Brazil, Argentina, and Chile.

DIPNOI AND CHIMÆRA

1. BARRAMUNDA (*Ceratodus Fosteni*): a, jaw and teeth; b, a lung, laid open; c, lung cell (enlarged).
2. DIPNOIAN SKELETON. (See article Dipnoi).
3. MUDFISH (*Lepidosiren*): a, mouth and teeth; b, a scale (enlarged).
4. CHIMÆRA: a, face; b, under side of head. (See article Chimæra).
5. BERRYBONE FISH (*Coccosteus declipens*).

were born in Crete about 580 B.C. Pausanias, in his *Ἑλλάδος Περιήγησις*, or *Itinerary of Greece*, states that they were pupils of (the mythical) Dædalus (q.v.). At Sicyon they executed statues of the gods, intended apparently for ornament in architecture rather than for devotional uses. Many works by them existed also at Ambracia, Argolis, and Cleonæ. A group of the Dioscuri and their sons in ebony and ivory at Argolis is of particular interest, as involving gold and ivory overlaying in statuette art. This method reached its perfection in the chryselephantine masterpieces of Phidias. Consult E. A. Gardner, *A Handbook of Greek Sculpture* (New York, 1911).

DIP OF THE HORIZON. See DEPRESSION.

DIP OF THE MAGNETIC NEEDLE. The angle which a magnetic needle makes with the horizon, or horizontal line, if the needle is so mounted as to swing freely about a horizontal axis and in a vertical plane passing through the magnetic meridian (direction pointed out by the compass). At the magnetic pole the needle stands vertical; at the magnetic equator it is horizontal. *Dip* has periodic variations, but of less relative magnitude than those of the magnetic declination. Since the year 1700 the dip at London has changed about seven degrees, and the daily inequalities do not ordinarily exceed two or three minutes. See TERRESTRIAL MAGNETISM; INCLINATION; COMPASS; DIP CIRCLE.

DIPO'LIA, or **DI'PO'LIA** (Lat., from Gk. τὰ Διπόλια, Διπόλια, Διπόλεια, from Δι, *Dii*, to Zeus + πολίεύς, *polieus*, guardian of the city, from πόλις, *polis*, city). An ancient Athenian festival celebrated annually on the fourteenth day of the month Scirophorion (June to July) to Zeus Polieus (Ζεὺς Πολιεὺς), the protector of the city. It was called *Buphonia* (q.v.) from the sacrifice of an ox, which was the principal feature of the celebration. Grain and sacred cakes were laid upon the altar of Zeus on the Acropolis. When the ox, brought before the altar, began to eat the grain, he was felled with an axe by the priest, who at once fled, throwing away the axe. The priest and the axe were subsequently arraigned in the Prytaneum and the axe was condemned and thrown over the borders of Attica. The whole ceremony seems to have originated at a time when the plow-ox was accounted sacred, so that even for the sacrifice of the ox to the gods atonement must be made. Consult Mommsen, *Feste der Stadt Athen* (Leipzig, 1898).

DIPPEL, dip'pel, ANDREAS (1866-). A German singer, born in Cassel. He studied music in Berlin, Milan, and Vienna, and made his first appearance in 1887 in Bremen as Pilot in *The Flying Dutchman*. Afterward he sang in opera in London, Breslau, Vienna, and Bayreuth and in 1890-92 and 1898-1901 in the United States. In 1902-03 he made a concert tour in the United States, and in 1904-06 he again sang in opera in this country. From 1908 to 1910 he was joint director with Gatti-Casazza of the Metropolitan Opera House. In 1910 he organized the Chicago Opera Company, of which he was director till 1913. In 1914 he appeared as impresario of an excellent comic opera company, producing the better class of light opera and operettas.

DIPPEL, JOHANN KONRAD (1673-1734). A German religious enthusiast and alchemist. He was born near Darmstadt, Aug. 10, 1673, studied at Giessen, lectured on alchemy in

Strassburg, but was expelled for alleged disorderly conduct, and henceforth led a wandering life. In 1697 and 1698 he published works attacking the Lutheran theology. From 1719 to 1725 he was imprisoned in the Danish fortress at Bornholm for his incautious remarks upon the Danish government, then went to Sweden, but thence he was banished through the influence of the clergy. He died at Berleburg, April 25, 1734. He was the discoverer of Dippel's oil and Berlin blue. He wrote several works under the pseudonym Christianus Democritus. For his *Life*, consult W. Bender (Bonn, 1882).

DIPPEL'S ANIMAL OIL (first prepared by J. K. Dippel in 1711). One of the products of the destructive distillation of bones. In the crude state it forms a thick viscid oil of a brown color and a very disagreeable odor, but on redistillation it may be obtained limpid and colorless. When taken internally in moderate doses, it acts as an antispasmodic and stimulates the vascular and nervous systems, but it is no longer used in medicine.

DIP'PER. The common American name for the constellation Ursa Major (q.v.).

DIPPER. 1. A small, somewhat thrushlike bird of the family Cinclidae, having an almost straight, compressed, sharp-pointed bill; compact, waterproof plumage, and extraordi-

THE AMERICAN DIPPER.

nary habits. Dippers frequent clear, pebbly streams and lakes, feeding chiefly on mollusks and on aquatic insects and their larvæ, which they seek even under water, diving with great facility, and moving about for a short time at the bottom of the water. They carry their rather short tails elevated after the manner of wrens, which they also resemble in their frequent tipping of the body, a dipping of the head accompanied with an upward jerking of the tail. The common European dipper, water ouzel, or water crow (*Cinclus cinclus*, or *aquaticus*), is a bird smaller than any of the British thrushes, of a generally dark-brown color, with throat and upper part of breast pure white. It is found chiefly in hilly or mountainous districts and is not gregarious. The dipper never fails to attract notice, as it sits upon some stone in the midst of or beside the stream, its white breast rendering it conspicuous as it repeats the movements from which it derives its name. It builds a very curious nest of interwoven moss, domed and with the entrance in the side, usually in some mossy bank close by a stream, and often near or under a cascade.

The eggs are pure white. The assertion that the dipper walks without apparent muscular effort at the bottom of the water is incorrect; its feet are not well formed for walking, and it scrambles about under water by help of its short wings, clinging and clambering about by means of its toes. The statement, also often made, that it eats the spawn of salmon and other fishes, in the belief of which it is much persecuted in Scotland, has proved erroneous. It feeds chiefly on the larvæ of aquatic insects. About 12 species of dipper are known, one of which (*Cinclus mexicanus*) is found in the mountains of western North America from Alaska to Mexico; this lacks the pure white under parts of the European species, but otherwise resembles it closely. Its habits have been eloquently described by Muir, in "The Humming-Bird of the Californian Waterfalls," an illustrated article in *Scribner's Monthly* (New York, 1878). Consult also Keyser, *Birds of the Rockies* (Chicago, 1902), and Dawson, *The Birds of Washington* (Seattle, 1909).

2. The bufflehead, or spirit duck. See **BUFFLEHEAD**.

DIPPING NEEDLE. See **DIP CIRCLE**.

DIPROTODON (Neo-Lat., from Gk. *δι-*, *di-*, double + *πρώτος*, *prōtos*, first + *ὀδών*, Ionic for *ὀδούς*, *odous*, tooth). An extinct herbivorous marsupial, of the size of a rhinoceros, related to the wombats and phalangers, and found fossil in the Pleistocene deposits of Australia. The skull is heavy, about 3 feet in length, and has a peculiar dentition. There are no canine teeth; the inner pair of upper incisors are enlarged, elongated, and chisel-shaped, like those of rodents. The lower incisors, two in number, are likewise elongated to meet those of the upper jaw, and, like these, they grew from persistent pulps; i.e., they continued to grow from their roots as they were worn away at their crowns, after the fashion of the incisors of rodents. Another related but somewhat smaller genus, *Nototherium*, the remains of which are found with those of *Diprotodon*, has a very similar dentition. These two fossil genera are the giants among the marsupials. See **MARSUPIALIA**.

DIP'SACUS. See **TEASEL**.

DIP'SAS (Gk. *διψάς*, *venomous* snake, whose bite caused intense thirst, from *διψα*, *dipsa*, thirst). A genus, or family, of tropical serpents—the nocturnal tree snakes. See **TREE SNAKE**.

DIP'SOMANIA (Neo-Lat., from Gk. *διψα*, *dipsa*, thirst + *μανία*, *mania*, madness). A variety of periodic insanity. The patient manifests during certain periods an uncontrollable desire for alcoholic liquors and drinks to great excess, while during the intervals he abstains entirely from the use of liquor and seems mentally sound. The dipsomaniac is not a drunkard nor a "moderate drinker." He often experiences a positive aversion for the smell and taste of liquors, but when the imperative appetite seizes him, after a period of abstinence and of orderly, refined, and irreproachable conduct, he abandons himself to unrestrained indulgence. The intervals of sobriety are apt to become shorter and shorter. Dipsomania is a degenerative insanity, i.e., an insanity dependent upon an hereditary or acquired constitutional condition. The outlook for recovery is bad. Imbecility and dementia often result.

DIP'SOSAURUS (Neo-Lat., from Gk. *διψα*, *dipsa*, thirst + *σαῦρος*, *sauros*, lizard). A small, remarkable iguanid lizard (*Dipsosaurus dor-*

salis) of the Colorado and Mohave deserts and Lower California, known as the desert iguana, or keel-backed lizard. It has a very small head, a conspicuous ridge of keeled scales along the

HEAD OF DIP'SOSAURUS DORSALIS.

back, and a long, compressed tail. It is sand-colored, with obscure blotches on the sides, and the sides and legs streaked with brownish red. It is a strict vegetarian, feeding wholly on buds and flowers. Its nearest ally is the collared lizard (q.v.). The tail is very brittle and is often shaken off if the lizard is picked up by it.

DIP'TERA (Neo-Lat. nom. pl., from Gk. *δίπτερος*, *dipteros*, two-winged, from *δι-*, *di-*, double + *πτερόν*, *pteron*, wing). An order of insects, the flies, characterized prominently by the development of only two wings, which are the front pair and membranous, while the posterior pair is represented by two club-shaped organs known as halteres, or "poisers," and by having mouth parts fitted only for sucking and piercing, but not for gnawing. Their metamorphosis is complete. See **FLY**.

DIP'TERUS (Neo-Lat., from Gk. *δίπτερος*, *dipteros*, two-winged). A genus of fossil dipnoin fishes of the family Ctenodontidae, found in the Old Red Sandstone of the Scottish Devonian. The body is small, rather slender, tapering gradually towards the heterocercal tail, and is covered by circular enameled scales. The head is low and blunt anteriorly, and the skull bones are small and numerous. There are a pair of pectoral fins and two dorsal fins, situated posteriorly, opposite the pelvic and anal fins, and all of these have their bases covered for a considerable distance with the enameled scales of the body. For recent works on this group, consult Eastman, "Devonian Fishes of Iowa," in *Report of the Iowa Geological Survey*, XVIII (Iowa, 1908). See **LUNGFISH**.

DIPTYCH, *dipt'ik* (Lat. *diptycha*, nom. pl., neuter, from Gk. *δίπτυχος*, *diptychos*, folded double, from *δι-*, *di-*, double + *πτύχῃ*, *ptychē*, fold, from *πτύσσειν*, *ptyssein*, to fold). A double writing tablet, or two writing tablets which are joined by hinges. Herodotus speaks of such a tablet, made of wood and covered with wax. It was in the later Roman time, however, that they were most used; those which have been preserved belong chiefly to the period when classical was merging into mediæval life. The beautiful carving with which they are often covered on the outside, consequently, represents not unfrequently a combination of classical and of Christian subjects. Ivory and metal were sometimes employed in place of wood; but the construction was always the same, the wax with the writing being in the inside. Under the emperors diptychs were distinguished as consular and ecclesiastical. The former, which were presented by the consuls, prætors, and ædiles to their friends, and those officially connected with them, on their entrance into office, were inscribed with their names and bore their

portraits. They served also, often, as New Year's presents. The extant specimens range from 406 to 541 A.D. For an illustration, consult Smith, *A Dictionary of Greek and Roman Antiquities*, vol. i, p. 643 (3d ed., London, 1890). The ecclesiastical diptychs, on the other hand, are decorated with scenes from sacred history and were preserved in the churches as part of the sacred ornaments. Those that exist are of various sizes, rarely exceeding 8 by 4 inches. They contain lists of contributors, of deceased members of the community who deserved special recognition, of saints and benefactors, particularly of the bishops. These lists were long read aloud in the churches. See ΤΡΙΠΤΥΧΗ.

DIPYLON GATE (Gk. διπύλον, from δι-, di-, double + πύλη, pylē, gate), THE. The most important gate in ancient Athens, in the Themistoclean Wall, between the inner and the outer Ceramicus (q.v.). It consisted of two sets of double gates, separated by a court about 127 by 70 feet. From it the Sacred Way led to Eleusis (q.v.). The dead were buried near the gate, and in the vicinity a number of beautiful ancient tombs are in part preserved. Portions of its foundations and remains of the walls of Themistocles still exist. Consult E. A. Gardner, *Ancient Athens* (London, 1902), and Weller, *Athens and its Monuments* (New York, 1913).

DİR, dēr. An independent state of India, in the Northwest Province, 175 miles northwest of Srinagar (Map: India, B 1). It commands the route between Chitral and Peshawar. Pop. (est.), 100,000.

DİRCE, dēr'sē (Lat., from Gk. Διρκή, *Dirkē*). A famous fountain and stream at Thebes, named, according to Greek story, after Dirce, the wife of Lycus, King of Thebes. Dirce had sorely persecuted Antiope, who at last escaped to Mount Cithæron, where her twin sons, Amphion and Zethus, had been brought up by a herdsman in ignorance of their parentage. Here Dirce, while celebrating the rites of Dionysus, found her, and ordered Amphion and Zethus to bind her to the horns of a wild bull, that she might be dragged to death. They were about to execute the command, when by the aid of the herdsman they learned their relationship to Antiope and thereupon inflicted upon Dirce the punishment she had designed for their mother. See AMPHION.

DİRCKS, HENRY (1806-73). An English civil engineer and author, born in Liverpool. He began to lecture on chemistry and electricity in 1827. Afterward he became distinguished as a railway and mining engineer, in which capacity he made several inventions. The unique mechanical device known as "Pepper's Ghost" was invented by him, and described in the work entitled *The Ghost, as Produced in the Spectre-Drama, Popularly Illustrating the Marvellous Optical Illusions Obtained by the Apparatus Called the Dircksian Phantasmagoria* (1863). His other works include: *Jordan-Type, otherwise called Electrotpe* (1852); *Perpetuum Mobile* (1861); *Inventions and Inventors* (1867).

DIRECT (Lat. *directus*, straight, from *dirigere*, to direct, from *di-*, apart + *regere*, to guide), and **RETROGRADE** (OF. *retrograde*, Fr. *retrograde*, Lat. *retrogradus*, moving backward, from *retro*, backward + *gradi*, to go). In astronomy, the motion of a planet is said to be direct when the planet goes forward by its proper motion in the zodiac according to the succession or order of the signs (i.e., from

west to east), or when it appears to do so to an observer. On the other hand, it is said to be retrograde when it appears to go the contrary way.

DIRECTOR. A person chosen to act on a board of managers to control the affairs of a business corporation or joint-stock company. Officers acting in a similar capacity for eleemosynary corporations are usually, though not necessarily, known as trustees. The director is usually a stockholder of the corporation and elected to his position by vote of the stockholders, the length of time for which he may hold his office and the manner of his election being determined by the by-laws of the corporation.

The director is in a certain sense the agent of the corporation. He represents the corporation and not its stockholders, and, while not strictly a trustee, he acts in a fiduciary capacity, and his responsibility is not unlike that of a trustee. At common law the director is under no personal liability for the debts or obligations of the corporation. He is, however, liable to the stockholders in an action of tort for gross negligence or misfeasance in office resulting in loss to them. He is prohibited from using his position of trust for personal profit, and his contracts made with the corporation for that purpose may be set aside on application of a stockholder to the courts.

Generally speaking, the directors, acting as a board or through properly appointed agents, have authority to do any act in the line of the legitimate business of the corporation which the company may itself do under its charter; but they may not totally change that business nor dispose of what is essential to its existence or to the carrying out of its purposes without the consent of the stockholders. Yet in some jurisdictions they may by their act bind the corporation to do acts which are strictly ultra vires. See CORPORATION.

In practice, much of the business of the board of directors is transacted by a committee of its members, usually termed an executive committee, whose powers are defined by the by-laws of the corporation or by vote of the board of directors. In boards of bank directors in England a distinction is made between ordinary and extraordinary directors, the former conducting the business in its details, the latter having little to do with the actual business, and in reality being honorary officers who allow their names to be used to benefit the undertaking by the distinction attached to them from their personal or financial position. This practice is not common in the United States, though not unknown. The disposition of the profits of the corporation is, under most charters, left largely to the directors. Thus they may, if they choose, apply profits to the extension of facilities or purchase of new plant, or other improvements, rather than to dividends, in their discretion and without a vote of the stockholders.

Modern statutes have increased the liability of directors of corporations to an extent varying considerably in the different States of the Union. A provision sometimes made is one making directors personally liable for the debts of the corporation if they do not file annually with the Secretary of State a report upon the affairs and business of the corporation. Under the special English statutes known as the Joint Stock Companies Acts the duties and responsi-

bilities of directors are very clearly defined. It is provided that if the directors of a company declare a dividend when the company is known to them to be insolvent, or declare a dividend to pay which would to their knowledge make it insolvent, they shall be personally liable for the debts of the company to an amount equal to the dividend declared under such circumstances; in the United States the common law on this point generally prevails.

It is customary to pay directors a slight fee for their services, but this is usually insignificant in comparison with the interests involved; usually the motive of the director in taking the office is the prosperity of the concern as benefiting him in the position of a stockholder. See CORPORATION; and consult the authorities there referred to.

DIRECTOR OF PUBLIC PROSECUTIONS.

An office created by Act of Parliament in 1879 (the Prosecution of Offenses Act, 42 and 43 Vict., c. 22) to systematize and direct the prosecution of criminal and certain other public offenses in England. Originally an independent department of the crown, the office was in 1884 (47 and 48 Vict., c. 58) merged in that of the Solicitor to the Treasury, who now, subject to the Attorney-General, acts as public prosecutor. Prior to this legislation the prosecution of criminal offenses was a haphazard affair, being left to the enterprise of private complainants. The public prosecutor now exercises substantially the functions of the district attorney in the criminal administration of the United States.

DIRECTORS, INTERLOCKING. See INTERLOCKING DIRECTORATES; TRUSTS; RAILWAYS.

DIRECTORY (Fr. *directoire*, from Lat. *dirigere*, to direct). The name given to the executive government in France from Oct. 28, 1795, to Nov. 9, 1799. After the overthrow of the ultra-Jacobins the moderate Republicans promulgated a new constitution, that of the year III, which provided for a government of two councils. The Council of Five Hundred was to propose the laws, the Council of Ancients was to pass on them. As executive head, five members, chosen from both bodies, were to act. The first five directors chosen were Barras, Carnot, Rewbell, La Révellière-Lépeaux, and Letourneur. Each was to preside for three months at a time, and one had to retire every year. Though the foreign policy of the Directory was successful at first, the brilliant campaigns of Moreau in the North and Bonaparte in Italy resulting in the Treaty of Campo Formio, which isolated England and made possible Bonaparte's Eastern campaign, yet its essential weakness was later shown in the notorious "X. Y. Z." negotiation with the United States, and its defeat by the Second Coalition. Meanwhile its management of home affairs was corrupt and incompetent in the extreme. The members formed factions, and Barras, with his associates La Révellière and Rewbell, succeeded in ousting the other two directors, Carnot and Barthélemy, who had succeeded Letourneur, by the coup d'état of 18th Fructidor (Sept. 4, 1797). At the end of that year the Directory consisted of Barras, Ducos, Gohier, Moulins, and the Abbé Sieyès; but the last of these had begun to plot against the constitution, and the military disasters of 1799 furnished a pretext for its overthrow by the coup d'état of the 18th Brumaire (Nov. 9,

1799), which resulted in the establishment of the Consulate (q.v.), with Napoleon as First Consul. Consult: Granier de Cassagnac, *Histoire du Directoire* (3 vols., Paris, 1863); Barranté, *Histoire du Directoire* (3 vols., ib., 1855); Pierre, *La Terreur sous le Directoire* (ib., 1887); Sciout, *Le Directoire* (4 vols., ib., 1895-97); Sorel, *L'Europe et la révolution française* (8 vols., ib., 1910); Guyot, *Le Directoire et la paix de l'Europe* (ib., 1911). See FRANCE.

DIRECTORY FOR THE PUBLIC WORSHIP OF GOD. A code of regulations which governs public worship in the Church of Scotland and supplies the place of the Anglican Book of Common Prayer. It was compiled by the Westminster Assembly in 1644, by order of both houses of the English Parliament, and was adopted by the Church and the Parliament of Scotland in 1645. Many of its regulations are still adhered to by the Scottish Presbyterian church.

DIRECT PRIMARIES. See ELECTORAL REFORM; PRIMARY ELECTIONS.

DIRECTRIX OF A CONIC. A straight line perpendicular to the axis, by reference to which the nature of the conic may be defined. Assume an indefinite straight line as the directrix, and a point without the directrix as the focus; then, if a line is revolved about the focus, any point moving in the line will generate a curve, which will be a conic section (q.v.), provided there is a constant ratio between the distance from the moving point to the focus and the perpendicular distance from the point to the directrix. The curve is an ellipse, a parabola, or an hyperbola, according as the distance from any point of the curve to the focus is less than, equal to, or greater than the perpendicular distance from the point to the directrix. The constant ratio mentioned is often called the determining ratio of the conic. In the figure DD'

represents the directrix of a parabola, F the focus, O the vertex, and P any point on the curve. According to the determining ratio, $PM = PF$. The focus is the pole of the directrix, and the directrix is the polar of the focus. Quadric surfaces also have directrices. See POLE AND POLAR; CYLINDER.

DIRGE. See ELEGY.

DIRICHLET. də'răsh'lă'. PETER GUSTAV LE-

JEUNE (1805-59). A German mathematician. He was born at Düren and was successively professor of mathematics at Breslau, Berlin, and Göttingen, where he succeeded Gauss in 1855. His memoirs on the theory of numbers are important, the most original being that on the determination of means with application to the distribution of prime numbers. He has also permanently influenced the theory of mechanics by his work on potentials. His papers on the theory of numbers were edited by R. Dedekind (Brunswick, 1879-81). His work on the theory of potentials was edited by F. Grube (Leipzig, 1887). His collected works were edited by Kronecker (Berlin, 1889-97).

DIRIGIBLES. See **AÉRONAUTICS**.

DIRK. A name used especially to designate the knife or dagger of the Scottish Highlander. Formerly worn under the vest or on the waist belt. See **DAGGER**.

DIRKSEN, dĕrk'sĕn, **HEINRICH EDUARD** (1790-1868). A German jurist. He was born at Königsberg and studied at Heidelberg and Berlin. In 1817 he was appointed professor of Roman law at the University of Königsberg, where he remained until 1829, when he received a call to Berlin. He was one of the greatest authorities of his time on the history and sources of Roman law, to which subject he contributed the following valuable works: *Zinlittische Abhandlungen* (2 vols., 1820); *Beiträge zur Kunde des römischen Rechts* (1825); *Manuale Latinitatis Fontium Juris Civilis Romanorum* (1837-39). Consult F. D. Sanis, *Zur Erinnerung an Dirksen* (Leipzig, 1870).

DIRSCHAU, dĕr'shou. A town of Prussia, in the Province of West Prussia, on the Vistula, about 19 miles southeast of Danzig (Map: Prussia, H 1). The river is here crossed by two fine bridges. The chief articles of manufacture are sugar, agricultural implements, and cement. There are also large machine shops and car works. Pop., 1900, 12,800; 1910, 16,894. Dirschau received municipal rights in 1260, and in 1308 it came into the possession of the Knights of the Teutonic Order. By the Peace of Thorn in 1466 it was given to Poland, but it became Prussian on the first partition of Poland in 1772. Consult Preusz, *Dirschaus historische Denkwürdigkeiten* (Danzig, 1860).

DIS, or **DIS PA'TER**. The Roman name for the god whom the Greeks called Pluto (q.v.).

DISABILITY. As a legal term, the want of power to do a particular act or class of acts. It may result from bodily or mental incapacity or from a rule of law. Of the first sort is the disability referred to in accident insurance policies, which provide for payments to persons who by reason of physical injuries are unable to work; also in statutes which make provision for the support of poor persons who are physically or mentally incapable of procuring a livelihood. Other examples of this class are afforded by lunatics and infants of tender years. Disabilities, in a rule of law, are those attaching to aliens, to infants who have reached the age of discretion, to married women under the common law, and to other special classes of persons. The reasons for imposing these legal disabilities upon persons who possess natural capacity for action are various. Some disabilities are intended as a protection or benefit to their subject, while others are imposed either by way of penalty or for the protection of individuals or of society at large. An example

of the first class is the legal incapacity of the minor who has not reached years of discretion. For his protection the law denies him the power of binding himself by contract. Yet the law does not sever him from responsibility for his torts or crimes. His disability is allowed to operate as a shield, but not as a sword. To the second class belong the disabilities imposed upon criminals or upon aliens or upon those who are denied the exercise of the elective franchise or are disqualified from holding public office. For a more detailed account of the legal consequences of legal disabilities, see **ADVERSE POSSESSION**; **ALIEN**; **INFANT**; **HUSBAND AND WIFE**; **CONTRACT**; **DEED**; **LIMITATION OF ACTIONS**; **NEGLIGENCE**.

DISAPPEARING GUNS. See **ORDNANCE**.

DISAPPOINTMENT, CAPE. See **CAPE DISAPPOINTMENT**.

DISBARMENT. The act of depriving an attorney, counselor at law, solicitor, or barrister of his rights and is such. The power to disbar rests with the Inns of Court and in the United States with the superior courts to whom is committed the power of admitting to the bar. They may take this action, upon sufficient cause, on complaint of any one, or of their own motion, where the cause comes to their knowledge directly. It may be exercised when an attorney has been guilty of gross contempt of court, dishonesty, extortion, or professional misconduct of a serious nature, and in some jurisdictions where he becomes a person of general bad character, so that he cannot be considered a fit person to be intrusted with the legal business of others. He must be given an opportunity to be heard in his own behalf, usually in open court, and may cross-examine any witness who may testify against him, and produce witnesses in his own favor, much as if he were under indictment for a crime. It is considered a severe penalty, as it deprives the person from earning a livelihood by his profession, and is only imposed in grave cases and after a thorough investigation and consideration. Where the conduct has been culpable, but there is reason to believe that it will not be repeated, the court will sometimes suspend the attorney from practice for a definite period, on the expiration of which he resumes his former rights and privileges. The court may restore one who has been disbarred to practice, in its discretion, where proof is presented that he will probably conduct himself properly in the future. See **ATTORNEY**, and consult the authorities there referred to; see also **BARRISTER**; **COUNSELOR**; **SOLICITOR**; **COURT**; **INNS OF COURT**.

DISCANT. See **DESCANT**.

DISCHARGE (OF. *descharge*, from *descharger*, Fr. *décharger*, It. *discaricare*, *scaricare*, from ML. *discargare*, *discarricare*, to unload, from *dis*, away + *carricare*, to load, from Lat. *carrus*, car, from Gall. *carros*, Ir., Welsh, OBret. *carr*, car), **MILITARY.** At military law an enlisted man is, in general, entitled to his discharge from the service in writing when he has completed his term of enlistment. He cannot be discharged before the expiration of his term except (1) by order of the President; (2) by sentence of a general court-martial; (3) on a certificate of disability; (4) on a writ of habeas corpus. A discharge is either honorable, dishonorable, or without honor, depending upon the character of the service rendered and the

circumstances under which it is given. The President may, in his discretion, permit a soldier to purchase his discharge. By order of the President the authority to permit a soldier to purchase his discharge has been delegated to commanders of divisions and territorial departments. An officer failing on a reexamination is honorably discharged with one year's pay from the army. Consult *United States Army Regulations* (Washington, 1913).

DISCHARGE BIBLE, THE. See **BIBLE**, CURIOUS EDITIONS OF.

DISCHARGE OF ELECTRICITY THROUGH GASES. See **ELECTRICITY**.

DISCIPLES OF CHRIST, or CHRISTIANS. This religious body, sometimes called, without its consent, "Campbellites," represents a movement in the Church in the interest of union by a return in faith and life to the Christianity of the New Testament. They are distinctly American in their origin. Simultaneously in different sections of the country arose teachers among the religious denominations who pleaded for the Bible alone without addition in the form of creeds or formulas of faith, and for the union of Christians of every name upon the basis of the Apostles' teaching. This movement assumed most notable proportions in western Virginia and Pennsylvania, and in Kentucky. Thomas Campbell and his son Alexander (q.v.), of Bethany, Va., renounced the Presbyterian system and were immersed in 1812, and with the congregations they had formed united with the Redstone Baptist Association, and, 10 years later, with the Mahoning Association. In 1823 Alexander Campbell began to set forth with great vigor and learning, in a periodical entitled *The Christian Baptist*, a plea for the simple gospel order of things, as under the Apostles. It was not a reformation he urged, but "a restoration"; not the organization of a new sect, or the reformation of an old one, but a return to Jerusalem, the renewal of the ancient landmarks of the Christian religion, the restoration of apostolic Christianity, its doctrines, ordinances, and fruits. His protest against human creeds as bonds of union, and plea for the all-sufficiency of the sacred Scriptures, aroused opposition, and the views he advocated were in many quarters denounced as heterodox. Great numbers, however, accepted them, and under the preaching of Campbell and Walter Scott, an evangelist of the Mahoning Association, many new churches were formed, until the Baptists began to declare nonfellowship with these brethren, and they were forced to form themselves into distinct communities.

Barton W. Stone, a Presbyterian minister in Kentucky, began a similar movement to that of the Campbells in 1804. A church was organized at Cane Ridge, Bourbon County, accepting the Bible alone as possessing authority in the religious life, and the name "Christian" as a sufficient designation of all who believe on Christ. Correspondence between Stone and Campbell led finally to the union of the two movements in 1831.

In January, 1830, Mr. Campbell began the publication of the *Millennial Harbinger*, which he edited until his death in 1866. In his periodicals, by his preaching and debates, his views were widely circulated. In recent years the Disciples of Christ have made great advance in number, and along all lines of religious activity, until the statistics for 1913 show 9076

churches with 1,362,711 communicants. The report about 10,000 Bible schools, with an enrollment of about 900,000 children. They raised during 1912, \$1,038,338 for missions, home and foreign, and \$143,570 for other purposes. Among the 30 schools and colleges controlled by the church are Drake University at Des Moines Iowa; Ruth College, Indianapolis; Hiram College, Hiram, Ohio; and Valparaiso University Valparaiso, Ind. Their strength lies chiefly in the north central States.

In agreement with what are termed Evangelical Christians, the Disciples accept the divine inspiration of the Holy Scriptures; the revelation of God in the tripersonality of Father, Son, and Holy Spirit; the all-sufficiency and alone-sufficiency of the Bible as a revelation of God's will, and a rule of faith and practice to His creatures; the divine excellency of Jesus Christ as the Son of God, His incarnation, doctrine, miracles, death as a sin offering, resurrection, ascension, and investment with supreme authority; the personal mission of the Holy Spirit to convince the world of sin, righteousness, and . . . comfort and sanctify Christians . . . of man from God and his dependence upon the divine mercy in Christ; the necessity of faith and repentance to salvation; the importance of baptism and the Lord's Supper as divine ordinances; the duty of observing the Lord's Day in memory of the resurrection of Jesus Christ; the necessity of righteousness, holiness, and benevolence in Christians; the divine appointment of the Church of Christ, composed of all who by faith and obedience confess His name, with its ministries and services for the edification of Christians and conversion of the world; the fullness of the gospel to all who will accept it on the New Testament conditions; the final judgment with the reward of the righteous and punishment of the wicked.

In disagreement with other Christians, the Disciples hold that while both Old and New Testaments are equally inspired, both are not equally binding upon Christians; the Old was God's will with reference to the Jews, the New is His will with reference to us (Heb. i. 1). Accepting fully the Scripture statements concerning the Godhead, they repudiate the philosophical speculations both of Trinitarians and Unitarians and do not use the theological terms common to the schools, but insist upon "the form of sound words" given in Scripture concerning Father, Son, and Holy Spirit. Accepting the Bible as an all-sufficient revelation of the divine will, they repudiate all authoritative creeds and human . . . fellowship. Receiving Jesus in all . . . and Christhood, they accept the truth that Jesus is the Christ, the son of the living God, as the one article of faith, as the creed of the church, the fundamental fact of Christianity, and belief with all the heart in Jesus as the Christ is all the confession of faith they ask preparatory to baptism and church membership. Recognizing the agency of the Holy Spirit in conversion, they repudiate all theories of special spiritual operations outside of the Word, demanding of the sinner that he shall hear, believe, repent, and obey the gospel in order to secure the remission of his sins. Admitting the necessity of faith and repentance, they submit no other tests, no human formula of belief, but on a confession of Christ and heartfelt desire to give up sin and work righteousness, men are baptized and received into

the church. Accepting baptism as a divine ordinance, they insist that "he that believeth and is baptized shall be saved"; they command men: "Repent and be baptized every one of you in the name of Jesus Christ for the remission of sins"; and claim that evidence of pardon and of the gift of the Holy Spirit is not in dreams and visions, but in the sinner's knowledge of his scriptural faith, repentance, and obedience to the gospel. Claiming the Lord's Supper to be a divine ordinance, they consider it not as a sacrament, but a memorial feast, and keep it on every first day of the week, meeting as the Lord's people and recognizing neither open nor close communion, since neither of these is known in the Scriptures of divine truth. On the Lord's Day, they hold it not as a Sabbath, but as a New Testament appointment in memory of the resurrection, to be observed as a day of rest and worship for the assembly and communion of saints, preaching of the gospel, administration of the ordinances, and training of families in the nurture and admonition of the Lord. Cherishing the Church of Christ, they regard it not as a sect, but a divine institution. They submit that sects are not branches of the Church of Christ, but are unscriptural. The body of Christ is one, of which Christ alone is the head.

The Disciples in regard to the action of baptism are in accord with the Baptists. Immersion is with them the only baptism that is scriptural and that could be universally accepted. As to the subjects of baptism, they baptize only believers in Christ. With respect to the design of baptism, they accord more with Pedobaptists. They baptize for "the remission of sins" and claim that the sinner in obeying this ordinance appropriates God's promise of pardon, relying on the divine testimony (Mark xvi. 16; Acts ii. 38). They date the beginning of the Christian institution on Pentecost, and the New Testament with them contains the history, constitution, and laws of the Church of Christ. In church government they are congregational and have no distinction of clergy and laity and recognize the local church with its elders and deacons as the highest ecclesiastical authority. They are ever, with district, State, and National conventions for missionary and benevolent work. These bodies are administered chiefly by the American Christian Missionary Society, with headquarters at Cincinnati, Ohio. In 1910 the society began a campaign to raise \$1,000,000 for American missions. This ends in 1915.

DISCIPLES OF SAINT JOHN. See CHRISTIANS.

DISCIPLINA ARCANI (Lat., discipline of the secret). A seventeenth-century term, applied to the custom of the early Church which treated certain rites as mysteries and withheld them from the knowledge of the uninitiated. There is no trace of this secret discipline before the end of the second century. It emerges into view during the third and is well established in the fourth and fifth centuries, which constitute its most flourishing period. The writers who set forth the mystery idea are Origen, Athanasius, Basil, Epiphanius, Chrysostom, Cyril of Jerusalem, Cyril of Alexandria, Theodoret, Ambrose, and Pseudo-Dionysius. It appears also in the Apostolic Constitution. From the sixth century onward, when Christianity had won the victory over paganism, we hear less and less of the secret. Its influence is clearly traceable in Eastern and Western Catholicism, even down to modern times (cf., e.g., the *Russian Catechism* of 1839).

Baptism and the eucharist were the two rites of the Church to which especially the mystery idea became attached. Baptism was called a "seal," or "illumination"; those baptized were "the initiated" and "the uninitiated"; the holy communion, the creed, and the Lord's Prayer were "mysteries." All this denotes assimilation of heathen modes of expression and of thought. The creed came to be regarded as a mystery because it was formally delivered to the catechumen at his baptism; the Lord's Prayer, because of its prominence in the communion office. These things were often withdrawn from public mention, or referred to only remotely, with such words as "the initiated know what I mean," etc. Symbolism was used, as in the famous inscription discovered at Arles in 1839: "Take the food, sweet as honey, of the saviour of the holy ones, and drink, holding the fish in thy hands"—words utterly profane, but perfectly clear, for whom the fish was the symbol of Christ, the initial letters of the Greek words for "Jesus Christ, Son of God, Saviour," forming the word *ixθῦς*, 'fish.' Sozomen will not include the Nicene Creed in his *History*, for fear some of the profane may read the book. Ambrose warns the Church to "guard against incautiously divulging the mystery of the creed or of the Lord's Prayer." Chrysostom explains reticence with regard to the latter by asserting that "no unbaptized person can call God his Father." Athanasius rebukes those who are "not ashamed to parade the sacred mysteries before catechumens, or, worst of all, even before heathen." It was the general opinion that familiarity with such sacred things must be guarded. Basil observes that "the revelation of the mysteries is preserved by silence." And Augustine goes so far as to assert that concealment, by provoking curiosity, helps along the extension of Christianity; for the uninitiated are eager to learn the secrets which the Church so carefully guards!

The reason for this custom lay in the circumstances of the early Church. The early Christians, surrounded by pagan populations who were only too prone to misinterpret their teachings, and severely persecuted by the government, naturally sought concealment and practiced a prudent reticence. Regarding their doctrines as a sacred deposit, they shrank from recklessly com-

municating them to the profane who might distort them. Experience had taught them, moreover, that all neophytes were not sincere, and the danger of betrayal by informers who pretended conversion led them to guard the more intimate doctrines and practices from catechumens until after a long probation. Further, it was not deemed wise to communicate the fullness of truth to the unprepared mind, and for this reason also the neophyte was only gradually inducted into the mysteries of the faith. The mysteries of the Græco-Roman and Oriental religions also had an influence upon the habits of thought of the early Christians. Roman Catholics hold that the discipline of the secret originated in apostolic times and urge that the words of Tertullian (*Præscript.* 41) indicate that it was already a well-established tradition in his day (150-230). Speaking of certain heretics, he says: "Among them it is doubtful who is a catechumen and who is not; all come in alike; they hear together and pray together." As regards its subject matter, Protestant writers generally contend that it embraced merely certain rites of worship, and that the silence of early Christian writers on certain doctrines is evidence that they were not held by the primitive Church. Roman Catholics hold that the system included doctrines as well as rites, and that it explains the silence of certain writers on points afterward held to have been handed down by continuous tradition. For the division of the eucharistic service into two parts, from the more sacred of which the unbaptized were excluded, see LITURGY.

For the Roman Catholic view, consult: Schelstrate, *De Disciplina Arcani* (Rome, 1685); for the Protestant view, Tentzel, *Dissertatio de Disciplina Arcani* (Leipzig, 1692); also in general, Bingham, *Antiquities of the Christian Church*, bk. ix (London, 1855); Hatch, *The Influence of Greek Ideas and Usages upon the Christian Church* (London, 1883); Anrich, *Das antike Mysterienwesen in seinem Einfluss auf das Christentum* (Göttingen, 1894); A. Weiss, *Die altkirchliche Pädagogik* (Freiburg, 1869); Wobbermin, *Religionsgeschichtliche Studien* (Berlin, 1896).

DISCIPLINE (Lat. *disciplina*, from *discipulus*, disciple, from *discere*, to learn). The method or code by which practices, rules, regulations, etc., are enforced. Applied to the individual, it implies a system of mental and moral training. In its military aspect it is the means by which the army in whole or in part is enabled to respond promptly and efficiently in answer to an order. It is the keynote of military efficiency and morale in that without it uniformity, organized effort, and the effective working of the complex machinery of a successful military organization are impossible. See TACTICS, MILITARY.

DISCIPLINE, ECCLESIASTICAL. The corrective and preservative function by which organizations for the purposes of religion seek to maintain their standards of order and conduct among their members. It is a function common to all religious bodies, though it varies greatly in the objects to be attained and the means used. While the standards to be maintained have continued substantially the same, the procedure and the punitive facilities at the command of the churches have undergone radical alteration. The changes have been due in large measure to the changed relations which the

churches bear to the state. At the close of its history the Christian Church followed a disciplinary procedure upon that in vogue in the Hebrew synagogues, where there were three degrees of punishment, all of which were species of excommunication. In the ancient Hebrew state the religious organization of society had the active cooperation of the political power in the enforcement of its discipline, which cooperation, however, was lost, with the loss of political independence. The Christian Church in the apostolic and subapostolic ages was in a similar position and lacked the aid of the civil power in the enforcement of its discipline. In the early ages of the Church certain crimes were subject to the discipline of public penance. We learn from Tertullian on *Purity* (c. 14, and 12) and from Pacianus that they can be reduced to the heads of infidelity, luxury, and homicide. St. Gregory of Neo-Cæsarea mentions the four classes into which the public penitents were divided. They were the weepers, the hearers, the prostrate, and those who remained (consistentes). The weepers were kept entirely outside the church door; the hearers were admitted just within the door; the prostrate, under the same rule as the hearers, were excluded from the most sacred portions of the service; the remaining penitents (consistentes) were allowed to hear the whole service, but could not receive the eucharist. (See ABSOLUTION; LAPSED.) When the church came to be recognized by the state as the normal organization of society for the purposes of religion, her disciplinary facilities were enormously increased because of the aid received from the civil power. What had before been considered merely conduct unbecoming a baptized Christian came in many cases to be a breach of the civil law, of which the civil authorities would take cognizance. This relation of states to the churches has continued in varying degrees in the different countries of Christendom. The ancient order has been most fully preserved, perhaps, in the Empire of the Russias, where the church is recognized by the state as the normal organization of society for the purposes of religion and where the police power of the state is in many cases at the disposal of the ecclesiastical authorities. In Western Christendom, however, the development of the sphere of individual liberty so as to include liberty of speech and action in religion has caused individual ecclesiastical relations to be largely voluntary and has reduced the punitive facilities of religious organizations to a minimum, never exceeding expulsion from the communion and church fellowship. The Church of Rome has, of all the churches, retained the most elaborate system of discipline, by the side of which has also been maintained a system of dispensations (see DISPENSATION), yet the penalties are merely ecclesiastical and not civil. It divides discipline into (a) dogmatic, which prescribes what should be believed, and (b) moral, which has to do with the conduct of life. In the Protestant churches discipline consists in the infliction of three penalties: (1) public censure, which is, as a rule, resorted to only after private admonition has been given; (2) suspension; and (3) excommunication. In Congregational churches discipline is administered by the church body. In the Presbyterian churches these powers are exercised by the session, an appeal lying to the presbytery, thence to the synod and general assembly. In the Methodist Episcopal church an accused member is brought

to trial before a committee of not less than five members, who shall not belong to the quarterly conference; if a majority find him guilty, the pastor executes the sentence, appeals being allowed to the quarterly and annual conferences. Unlike the voluntary bodies, the established churches, such as the Church of England and the Protestant establishments on the continent of Europe, have lost nearly all disciplinary powers over the laity, who have practically by virtue of citizenship the privileges of church membership.

In the United States church discipline is administered exclusively by church officials and judicatories. The complete separation of church and state deprives the civil tribunals of all power to revise or question ordinary acts of church discipline or of exclusion from church membership. If the rights of property and of personal liberty are illegally invaded by church discipline, the civil courts have authority to afford redress.

Whether a church member is amenable to ecclesiastical punishment is to be determined by the proper officers or judicatories of the particular church, in accordance with its rules of government and discipline. From their final decision no appeal lies to a civil court. In the language of the United States Supreme Court (*Watson vs. Jones*, Dec. 1871, 13 Wallace p. 728): "The law knows no heresy and is committed to the support of no dogma, the establishment of no sect. The right to organize voluntary religious associations to assist in the expression and dissemination of any religious doctrine, and to create tribunals for the decision of controverted questions of faith within the association and for the ecclesiastical government of individuals, congregations, and officers, within the general association, is unquestioned. All who unite themselves to such a body do so with an implied consent to this government and are bound to submit to it." The disciplinary authority of such bodies, and the rights and duties of their members, are governed by the same general rules of law that control in case of social or political clubs or other private organizations. See CANON LAW.

DISCIPLINE, THE. A form of self-castigation. See FLAGELLATION.

DISCLAIMER (from *disclaim*, OF. *disclamer*, *desclamer*, from ML. *disclamare*, to renounce, from Lat. *dis-*, apart + *clamare*, to claim; connected with Lat. *calare*, Gk. *καλεῖν*, *kaleîn*, to cry aloud). In law, a renunciation, repudiation, or disavowal of . . . or liabilities by words or conduct . . .

1. In actions involving real estate, a renunciation by a party of his character as tenant of one of the other parties to the action. Where a tenant sets up a claim of title in himself, superior to that of his landlord, or alleges that the one of whom he nominally is . . . is not the owner, or has not . . . in the property to execute a valid lease, and refuses to recognize him as his landlord, it is said to be a disclaimer, and, even if not sustained by the proof, works a forfeiture of the lease at the election of the landlord. A mere verbal refusal to recognize the lessor as landlord is not considered sufficient; it must be made where it will become a matter of record, as in a proceeding involving the rights of the landlord in the property. See EJECTMENT; LANDLORD AND TENANT.

2. The act by which a person refuses to accept an estate which is devised or conveyed to

him. This is usually accomplished by a deed or other writing, and, in order to be recognized without making application to the court, should be made before the devisee or grantee has in any way, by words or acts, shown assent to the devise or conveyance. It most frequently occurs where property is conveyed to one as trustee for another, and he does not care to assume the duties and responsibilities of the trust. See EQUITY; TRUST.

3. In equity pleading, a written statement by the defendant, disavowing or renouncing any interest in, or claim to, the matters set forth in the complainant's bill. It is a formal mode of defense and entitles the defendant to a hearing on the question as to whether he has any interest or connection with the matters in controversy, and, if he succeeds in . . . that he has not, he is entitled to an order striking out his name as party defendant. It does not deny any of the material allegations of the bill and is not available where facts are alleged which, if not controverted, would show a liability on the part of the defendant. Usually, therefore, it accompanies an answer, and the two pleadings are considered together. See PLEADING.

4. In patent law, a properly attested writing stating that the one who executes it is a patentee of a certain invention, and that he has discovered since filing his claim that he was not the first inventor of, and therefore wishes to eliminate from his claim a part of the thing which he originally included, through mistake or inadvertence, in the specifications, or statement of the nature and object of his invention. This should be attested by witnesses and filed and recorded in the Patent Office, and it is then considered as a part of the original specifications. The part which he seeks to retain must be clearly separable and . . . from the part eliminated and still be a patentable invention. Fraud or deception in making his original application will prevent a patentee from taking advantage of this rule. See INVENTION; PATENT; SPECIFICATION.

DIS'CO, or **DIS'KO**. A large island off the west coast of Greenland, in lat. 70° N. (Map: Arctic Regions, H 7). It is separated by a narrow channel from the Nugsuak Peninsula, and from the mainland on the south and east by Disco Bay. Disco Fiord deeply penetrates it from the west. The island has more than 3100 square miles and rises over 3000 feet. Godhavn, or Lieveby, on the south coast, is the seat of the Danish administration for northern Greenland and has 300 inhabitants.

DISCOBOLI (Neo-Lat. nom. pl., from Gk. *δισκοβόλος*, *diskobolos*, discus-thrower, from *δίσκος*, *diskos*, discus + *βάλλειν*, *balleîn*, to throw). A group of fishes characterized by the union of the rudimentary ventral fins to form the bony centre of a ventral sucking disk, enabling its possessor to attach itself to other objects. As now defined, the Discoboli include two or three families and about 50 species, inhabiting the northern seas, of which well-known examples are the lump-suckers (q.v., for illustrated details). Cuvier included the remora, a fish now placed in another group.

DISCOBOLUS (Lat., from Gk. *δισκοβόλος*, *diskobolos*). The thrower of the discus (q.v.). The most celebrated statue of a discobolus was executed in bronze by the Athenian sculptor Myron (q.v.). It is known from several marble copies, the best of which is a life-size statue in

the palace of Prince Lancelotti at Rome, found on the Esquiline in 1761. This statue represents the athlete at the moment of greatest muscular tension, when, having swung the discus back to the full stretch of his arm, he is about to hurl it forward with all his strength. Consult E. A. Gardner, *A Handbook of Greek Sculpture*, p. 238 (London, 1911). Another celebrated marble copy is in the Vatican; for a photograph of this and an account of the discus throwing, consult Gardiner, *Greek Athletic Sports and Festivals* (London, 1910). See Plate of GREEK ART.

DISCOGLOSSIDÆ (Neo-Lat. nom. pl., from Gk. *δίσκος*, *dískos*, discus + *γλῶσσα*, *glōssa*, tongue). The . . . frogs, a small family having many . . . of structure, prominently the disklike form of the tongue, and the fact that in the advanced tadpoles the breathing pore is in the middle of the under surface of the body instead of on the left side. The painted frog (*Discoglossus pictus*) of southern Europe is a typical form, and other representatives are the feuerkröte (q.v.), the African midwife frog (q.v.), and others of the genus *Alytes*, and a small species (*Liopelma hochstetteri*) of New Zealand, notable as the only amphibian native to those islands.

DISCOMYCE/TES (Neo-Lat. nom. pl., from Gk. *δίσκος*, *dískos*, discus + *μύκης*, *mykēs*, fungus). A name formerly applied to those groups of Ascomycetes (q.v.) whose ascocarps are open, . . . disks, saucers, cups, funnels, etc. . . . carps are seen most commonly on lichens.

DISCOPH'ORA. See JELLYFISH; MEDUSÆ.

DISCORD (OF. *descorde*, Fr. *discord*, It. *discordia*, *scordia*, from Lat. *discordia*, from *discors*, inharmonious, from *dis-*, apart + *cor*, heart). Sounds that have no harmonical relation whatever; differing from dissonance (q.v.), which in musical language is applied to sounds that are in . . . correct relation to one another, . . . nsonant. Discord is sometimes wrongly used for dissonance.

DISCORDAL STONES. See ARCHEOLOGY, AMERICAN.

DISCORDIA. In Roman mythology, the goddess of strife, known to the Greeks as Eris (q.v.).

DISCOUNT (ML. *discomputus*, from *discomputare*, to discount, from Lat. *dis-*, apart + *computare*, to reckon, from *com-*, together + *putare*, to cleanse, from *putus*, pure). A deduction from a stated price or from a sum due at a future time. Merchants often deduct a certain sum from an account if payment is made before the bill is due. Business houses commonly publish price lists which in course of time are corrected by means of stated discounts. Even double and triple discounts are common. Thus 10 per cent off 20 per cent off 40 per cent means a reduction of 40 per cent from the list price, and a reduction of 20 per cent from this amount, and finally a reduction of 10 per cent from this result. Such discounts are called *trade* or *commercial* discounts.

Banks, in purchasing promissory notes before they are due, customarily deduct from the amount of the note at maturity a certain per cent, called *bank* discount. In case of loans it is customary for banks to deduct the interest in advance, leaving the borrower an amount equal to the face of the note less the interest. The form of discount known as *true* discount is

now practically obsolete. It was computed thus: Divide the future worth of the note, i.e., its amount at maturity, by the future worth of one dollar, and the result is the present worth of the note. The difference between the future and present worth is the true discount. By discount is also meant the depreciation expressed as a rate per cent of the par value of a fixed investment; e.g., on railway stock bought at 115 and sold at 95, there is 20 per cent discount. The rates of bank discount vary according to the demand for money and the nature of the security. The range in the United States is approximately from 3 per cent to 10 per cent except in case of doubtful securities, where . . . es are exacted.

DISCOVERY (from *discover*, OF. *descouvrir*, Fr. *découvrir*, It. *discoprire*, from ML. *discopere*, to discover, from Lat. *dis-*, away + *copere*, to cover, from *co-*, together + *operare*, to cover), TITLE BY. The title or sovereignty acquired by a nation through the discovery by its agents or subjects of territory over which no other power exercises sovereignty. As the foundation for claim of title, discovery has ceased to be of practical importance with the disappearance of unexplored regions and has given place to *occupation* as a means of conferring proprietary or sovereign rights. International law considers discovery to give only inchoate title, which must be completed by occupation, by settlement or military posts within a reasonable period, and the untimely interference of another state with the territory affected might justifiably be construed as a hostile act. What acts are sufficient to effect absolute title, and what is a reasonable time, can only be determined by consideration of the circumstances of each particular case. For instance, the act of discovery is valid until a proper time has elapsed for the preparation of an expedition for permanent occupation. But this presumption ceases when standing alone, compared with acts of continuous or actual settlement by another power. Where exploration is made and other evidence of interest given, the extinction of the claim may be long postponed unless confronted by a definite act of appropriation by another state without protest. So, in conclusion, it may be said that the intention of a state to take possession of territory discovered by its subjects must be promptly signified in some unmistakable manner if it is to be available against foreign interests seeking a foothold. The same rule applies to occupation as a root of title.

The titles which Spain and Portugal first claimed in the New World were founded on papal grants. In 1493 Alexander VI granted to Spain all lands beyond a line 100 leagues west of the Azores. This was later modified by treaty with Portugal fixing a new line 370 leagues west of the Cape Verde Islands. Such claims were disregarded by the Protestant states, which sent out agents commissioned to discover and acquire any "heathen lands." These discoveries were made the basis of claim of title absolute and were of practical value in giving significance to subsequent acts in themselves doubtful or inadequate. The discovery was followed by some formal act of possession in the planting of a flag or erection of a monument as notice of the intention of the state to whom the expedition belonged. The claims based on these discoveries and confirmed

by later occupation and settlement developed the conflicts which have marked the history and determined the possession of the Western Continent. Writers on international law uniformly hold that discovery, to be effective, must be made by authorized agents of a state, or that, if made by a private citizen or subject, the act be promptly adopted by the government. This was declared to have been the weakness in the American case in the Oregon Question (q.v.). Captain Gray entered the mouth of the Columbia River in 1792 in a *trading vessel*. No recognition was made by the United States government at the time, and shortly afterward Captain Vancouver, engaged in surveying the coast for the British government, sailed several miles up its course. In 1811 the *Company of Astoria* was founded by the *British* Company, a private corporation. The dispute was settled by the Treaty of 1846 without expressly conceding the American claim. Africa furnishes almost the only territory to which the principles of discovery and occupation now have a vital application. In 1856 the United States adopted a code of rules to govern the rights of discovery of guano islands. Consult the authorities referred to under INTERNATIONAL LAW.

DISCOVERY, BILL OF. An equitable remedy which is sometimes used to enable a plaintiff or defendant in an action, either at law or in equity, to obtain information and proof as to facts and documents necessary for the prosecution or defense of his case, where such means of proof are within the knowledge or possession of the opposite party. The bill should not ask for any relief as to the matters in controversy, but may ask for an injunction staying further proceedings in the action until the discovery is obtained. It must only ask for the disclosure of facts or the production of deeds, writings, or other things in which the party has a title or interest, and which are essential to be established in order to sustain his side of the case, and must show some merit in his claim or defense. Thus, a devisee of real property under a will might maintain such a bill for the production of the title deeds of the particular property to which he has become entitled, in order to trace the deviser's interest, and consequently enable him to establish his claim. The bill must not demand any information which is clearly only in the nature of evidence for the opposite party, as it is not for the purpose of compelling him to disclose the manner in which he will endeavor to establish his side of the case. It will only be entertained in civil, not in criminal, actions. It is still a common remedy in States having separate courts of law and equity, but has been abolished or has fallen into disuse in States having codes of civil procedure, as in New York, where a party has a right to call his adversary as a witness and compel the production of books and documents by *subpoena duces tecum*. In England discovery is no longer confined to a bill in equity, but may be had on proper application to the High Court. See EQUITY; EVIDENCE; SUBPOENA.

DISCOVERY, THE. 1. The small ship in which Henry Hudson explored the northeastern coast of America in 1610. The vessel was later commanded by Sir Thomas Button, who discovered Nelson's River, and still later (1615-16), by Baffin and by Bylot. She was originally built (1602) by the East India Company, to discover the "Northwest Passage," under the

command of George Waymouth. 2. A steam vessel employed, together with the *Alert*, on the British Arctic expedition (1873-76) under Sir George Nares.

DISCRIMINANT. See EQUATION; DETERMINANTS.

DISCRIMINATION (Lat. *discriminatio*, from *discriminare*, to discriminate, from *discernere*, to discern, from *dis-*, apart + *cernere*, to perceive). A distinction made between patrons by one engaged in a public or common calling, such as that of common carrier or innkeeper. Such discrimination is a violation of a duty imposed by the common law. It is the legal duty of every one engaged in such a calling to serve all persons in the order in which they present themselves and to charge no one more than a reasonable rate. Speaking generally, he must treat all alike; he must afford equal accommodations and facilities to all, and he must not exact from any one an excessive rate for his services. Further than this, however, his common-law duty does not extend. He is at liberty to charge less than a fair rate to any one. Others, it is held, cannot justly complain of such favoritism, so long as his charges to them are reasonable in amount. In the language adopted by the New York Court of Appeals, "Re *Carriers*," preference in rates of compensation, the carrier's obligation is to charge no more than a fair return in each particular transaction, and, except as thus restricted, he is free to discriminate at his pleasure. This is the equal justice to all which the law exacts from the common carrier in his relations with the public." To put it in another way, the common law prohibits positive discrimination, but does not forbid negative discrimination. It does not permit the common carrier to transport one man's goods in preference to those of another; but it does allow him to carry for favored individuals at an unreasonably low rate, or even gratis.

When railways came into operation, their managers took advantage of this rule of the common law and made especially low rates to those who gave them their exclusive patronage as well as to those whom they chose for any reason to favor. This practice has evoked a good deal of legislation, both in England and in the United States, having for its object the prohibition of every form of discrimination or preference by carriers. The earliest statute on this subject is the act of Parliament known as the Railways Clauses Consolidation Act of 1845. Its main purpose was to prohibit a common carrier from charging more to one person than to another at the same time, it charged to others the same kind of service. It has served as the model for Federal and State statutes in the United States. In some of the States the principle has been embodied in constitutional provisions. This is a sound public policy. It operates to prevent great railroad corporations from building up the business of favored individuals to the injury of others.

The most important piece of Federal legislation bearing on this topic is that known as the Interstate Commerce Act of 1887. Its avowed purpose is to promote and facilitate commerce by the adoption of regulations to make charges for transportation just and reasonable and to forbid undue and unreasonable preferences or discriminations. The evils which it was intended to correct have been judicially described

as ordinarily taking "the shape of inequality of charges made, or of facilities furnished, which are usually directed by or tolerated for the promotion of the interests of the corporation itself, or for the benefit of some favored persons at the expense of others, or of some particular locality or community, or of some local trade or commercial connections, or for the destruction or crippling of some rival or hostile line." The act does not attempt, however, to prohibit all discriminations and preferences. It aims only at those which are unjust and unreasonable. It does not ignore the principles that one can sell at wholesale cheaper than at retail, nor that the carrier should be allowed to make a specially low rate to secure business which would otherwise go by other competitive routes. For later legislation, including that of 1906, see RAILWAYS.

See INTERSTATE COMMERCE COMMISSION and authorities there cited; consult also Beale, *On Bailments*, chap. xi (London, 1900); *Interstate Commerce Commission vs. Baltimore and Ohio Railroad*, 145 U. S. 263 (1892); *Texas and Pacific Railway vs. Interstate Commerce Commission*, 162 U. S. 197 (1896).

DISCRIMINATION, SENSIBLE, or DIFFERENTIAL SENSITIVITY. The name applied to an intellectual function of extreme importance—our capacity to pronounce upon the likeness or difference of sense presentations. The phrase "must not be taken to denote a faculty of comparison, in the sense of a peculiar conscious process existing alongside of the various contents. It merely expresses, in the first instance, the general fact that we have different experiences and experience them differently; in other words, it covers the introspection (q.v.) of different contents and the report of their difference. . . . But we also use it to indicate our experience of like contents, and our report of their likeness." (Kölpe.) The differential sensitivity would, then, be exercised if we were called upon to judge of the likeness or difference of two reds or of the *a* of two violins. In such cases we (a) experience the colors and tones in the same or in different ways; they make the same or a different impression upon our mind; while we then (b) formulate this experience in words, saying "like" or "different," as introspection dictates. The former process, of introspective discrimination, is termed the *direct*, the latter, of rendering the experience in words, the *indirect*, differential sensitivity. There are, then, two problems before us. We must ask, first, as to the conditions under which we are able to discriminate, and the limits within which discrimination is valid; and, second, as to the adequacy of language to reflect or reproduce the results of introspection.

1. A very little consideration suffices to show that an accurate comparison of sense contents cannot be undertaken in any and every case of difference; but that certain favorable conditions are necessary to a reliable judgment. Suppose, e.g., that we have two reds before us—a saturated red, and a reddish gray of the same tint. (See SATURATION.) It is impossible, with all imaginable care in comparison, to assert that the saturated red is three or four or any definite number of times as red as the less saturated color. The one impression is that of a "good" red; the other that of a dull or gray red; more we cannot say. Or suppose that three pressures are given—a light, a moderate,

and a heavy. It is impossible to assert with any confidence that the moderate pressure is three times as much heavier than the light as the heavy is than the moderate; we can say that the former difference is "a good deal greater" than the latter, but that is all. Now experiment has proved that the conditions favorable to exact discrimination are realized in two, and only in two, instances; and it is, accordingly, with these that investigators of the differential sensitivity have occupied themselves. The first instance is that of "difference determination," the second is that of "difference comparison." In the former procedure the aim is to determine the "just noticeable difference" between two like contents; in the latter, to effect an equality of sensation differences or sense distances. An illustration of difference determination appears under the title AUDITION (q.v.); it is found that two tones are discriminable, in the middle region of the musical scale, if their pitch numbers differ by 0.2 of a vibration. This value measures the just noticeable difference of tonal quality. As illustrations of difference comparison, we may take the following: given two tones, it is required to find a tone which lies, for sensation, midway between them; and, given a black and a white, it is required to find a gray which appears to be equidistant from both. Let the tones have, e.g., the pitch numbers 200 and 400; then the middle tone has (approximately) the pitch number 300; the stimulus distance 300-200 is equal, in sensation, to the stimulus distance 400-300. In other words, we have the required middle tone when we have the *arithmetical mean* between the two tonal stimuli. With the lights the case is different. Let the unit of black have the photometric value 1, and the unit of white the photometric value 60; so that a white disk (360°) stands to a black disk as 360×60 to 360×1 , or as 21,600 to 360. The middle gray is not the arithmetical mean, a disk of 180° white and 180° black (value 10,980). This mixture appears much too light. The middle point is found rather with a disk of some 41° of white and 319° of black, i.e., with a stimulus whose photometric value is approximately 2788, the *geometrical mean* between the limiting black and white. It is clear, then, that the course of the differential sensitivity is not the same for tones and for lights. By an extension of experiment to the qualities of the other senses, and to the sensation attributes other than quality (see SENSATION), various laws of the differential sensitivity have been established. (For an example, see WEBER'S LAW.) A valid determination of these laws is possible only on the condition that the sources of experimental error are strictly controlled by the investigator. Attention, expectation, and practice must be at their best; habituation and fatigue must be avoided (see these terms). The "constant errors" of time and space must also be ruled out; as many experiments must be taken in the time order *ab* as in the order *ba*, and as many with stimulus *a* to the right as with the same stimulus to the left; and the results of the double series averaged. Moreover, the instruction given to the observer must be specific and clearly formulated and must be frequently repeated, since the attitude which is set up by the instruction determines not only the direction of attention but also the mode of apprehension of the problem in hand.

So far we have spoken of the *magnitude* of the differential sensitivity. This may be expressed in two ways, absolutely and relatively. If, e.g., I can just distinguish a light of 50-candle power from one of 50.5-candle power, the value .5 gives a measure of the absolute, and the value $.5/50$ or $1/100$ a measure of the relative differential sensitivity. But we can also measure the *delicacy* of the discriminative function. An observer might, in one test, distinguish between lights of 50 and 50.2, while in the next . . . he could distinguish only between . . . Here the magnitude of the differential sensitivity, as averaged from the two tests, is .5; but the observer is evidently less delicate of discrimination than another who should give the values 50.4 and 50.6 in successive trials. Not only the average, but also the fluctuation of that average, must therefore be considered in a general measure of discrimination.

2. We turn to the question of the indirect differential sensitivity. And we must note, in the first place, that the importance of language as an instrument of psychology can hardly be overestimated. The flexibility and ready variation of the spoken sentence and the permanence of the written record are very great advantages. Still, language is discrete, while the stream of consciousness is continuous; so that, at the best, we are seeking, so to say, to reproduce a fresco by a mosaic. Moreover, the relation of the contents of consciousness to the words that describe them is not constant; while some experiences call up habitual and familiar phrases, others baffle us, cause us to pick and choose our terms, and to halt for the right expressions. We cannot, then, take it for . . . discrimination and the report . . . always run parallel, that the "good observer" is necessarily a "good reporter." The difficulty which here presents itself may be overcome by a fitting instruction given to the observer. Suppose, e.g., that the observer is asked to discriminate between two weights; he is instructed (1) to judge the second weight in terms of the first, and (2) to report the second weight as "heavier," "lighter," or "the same." Not only, as we have seen above, does such an instruction set up an attitude which determines the clear apprehension of the task, and the direction of attention to the specific problem; it also determines the exact terms in which the report is to be formulated. With practice such a report may become as automatic as the direct discrimination, so that a uniform series of results is assured. Consult: Fechner, *Elemente der Psychophysik* (Leipzig, 1889); Wundt, *Grundzüge der physiologischen Psychologie* (ib., 1910-11); Kuelpe, *Outlines of Psychology* (London, 1909); Titchener, *Experimental Psychology* (New York, 1905).

DISCUS (Lat., from Gk. *δίσκος*, *diskos*, disk) **THROWING**. An athletic sport. Originally the discus was a circular piece of stone (sometimes metal) about twelve inches in diameter, which the *discobolus* (Gk. *δισκοβόλος*), or thrower, in the ancient Greek games pitched from a fixed mark to the greatest possible distance; the competition of rival athletes constituting the game. In the ancient Olympic games discus throwing was one of the five exercises of the pentathlon, and it was introduced in the revival of the games at Athens in 1896. In this contest the discus must weigh 4 pounds, $6\frac{1}{2}$ ounces, and must be thrown from an 8-foot, $2\frac{1}{2}$ -inch

circle. Under these conditions an expert may throw the discus 140 feet or more. See DISCOBOLUS.

DISEASE, *dīz-ēz'*. "Any departure from, failure in, or perversion of normal physiological action in the material constitution or functional integrity of the living organism" (Foster's *Medical Dictionary*). Practically, a disease is a particular condition of ill health dependent upon some cause other than normal decay from age. Convenient, though not strictly scientific, is the division of diseases into functional and organic. A disease is organic if a certain organ is affected by it, changes occurring in the tissues. In a functional disease the organ in question does not properly perform its functions, but is itself intact; properly the disease exists elsewhere than in that organ, the organ being disordered as a reflex result of distant changes. Diseases are termed diathetic when dependent upon a predisposition or diathesis (q.v.); they are termed enthetic when arising from external causes entirely. Many diseases arising from the entrance and growth of bacteria from without are called germ diseases. . . . diseases are those caused by altere. . . . of the cells of the body. This altered function may be due to the action of bacteria, which are naturally found in the body, as in the digestive tract. The retention of feces in the intestine, or of uric acid or peptones and albumoses in the blood, causes disease from the generation of poisonous alkalis termed leucomaines. See BACTERIA; DISEASE, GERM THEORY OF; MEDICINE; DISTRIBUTION OF DISEASES.

Feigning of Disease. This is much practiced in the army and navy, and by convicts and others anxious to escape from discipline, or procure a discharge from compulsory service. It is also practiced by unfortunates who want to rest in hospitals during the winter, or by impostors who seek to gain money by arousing sympathy. It is technically called *walingering*. The detection of feigned disease, of course, necessitates the aid of the educated physician, and is . . . a thorough . . . of the reality, unless, indeed, the . . . be very crude. The diseases most commonly simulated are epilepsy, catalepsy, convulsions, blindness, deafness, paralysis, insanity, neuralgia, rheumatism, disease of the heart, and generally all disorders which may exist without leading to any distinct external appearances. Ulcers of the legs, however, have often been made, and kept open artificially through the application of irritant substances, and vomiting or coughing up of blood is very easily simulated. The detection of such impostures is easy or not according to the opportunities and knowledge and skill of the deceiver, as compared with those brought to bear on the discovery of the fraud. Careful testing is always necessary, as well as observation of the patient when he is unconscious of it. The medicolegal importance of this subject is decided. Many actions are brought against railroad companies to recover damages for alleged injuries resulting in nervous diseases. It rests with the neurologist to decide if such diseases exist, and none but an expert can determine the truth. The questions then arise whether the nervous disease existed before the injury, or whether it was aggravated by the injury so as to incapacitate the patient, or whether it has appeared since the injury and is due to a subsequent cause. For a consideration of the

question and an account of a family of malingerers, consult Bailey, *Diseases of the Nervous System Resulting from Accident and Injury* (New York, 1906).

DISEASE, GERM THEORY OF. The theory that several enthetic diseases are caused by entrance into the body of germs of a vegetable nature, which during their growth produce chemical changes and give rise to chemical products. These chemical products, like other poisons, alter functions, disturb the processes of nutrition and repair, and cause disease. The germ theory, in a less accurate form, was proposed by a few investigators as early as the seventeenth century. (See BACTERIA.) Van Leeuwenhoek's discovery and description of the microorganisms which his imperfect optical instruments brought into view interested Lange and Hauptmann, who theorized at once on the important rôle the misnamed "animalcules" might play in the production of disease. Among the maladies which they considered to be probably due to *contagium animatum* were epilepsy, gout, pleurisy, typhus fever, measles, smallpox, and puerperal fever. In 1701 Andry and Linné announced that syphilis has a similar origin. Lancisi, in 1718, made a parallel claim for malaria. Following these most valuable deductions and theories came the publication, in 1762, of the results of the investigations and deductions of Antonius Plenciz, a Viennese physician, who declared that all infectious diseases were caused by microorganisms, and that the infective material consisted of either minute living animals or plants, letting a flood of light upon the whole subject through these brilliant discoveries of the truth. He stated his belief that differences in the length of the period of incubation of diseases were due to differences in the time of development of special germs, as they multiplied in the body. He suggested the conveyance of germs through the air. He made original investigations into the nature of the processes of putrefaction and fermentation, and stated, as a conclusion reached by his deductions, that such processes result from the presence, growth, and multiplication of living organisms. Following the publication and discussion of these statements arose the theory of spontaneous generation of minute animal and vegetable organisms, advocated by Needham, in 1749, after loosely conducted experiments. Bonnet, in 1762, Lazarus and Spallanzani in 1769, Schultze in 1836, Schwann in 1837, Helmholtz in 1843, Schroeder and Von Dusch in 1854, Hoffmann in 1860, Chevreul and Pasteur in 1861, all contributed results of accurate scientific experiments which showed the absolute falsity of the theory of spontaneous generation. But, incredible as it may now seem, it was not till 1876 that the combined results, philosophical, chemical, and biological, of Tyndall and Cohn set the question at rest and established the fact that "all life comes from life," to use the words of Harvey's law. About 1873 the germ theory of disease was authoritatively restated, and germ causation became an accepted principle.

Germs in the Body. The question as to how germs enter the body and the means of defense against them which the body possesses is one of extreme importance. When we think of the omnipresence of germs, in the air we breathe, in the water we drink, in much of the food we eat, in the soil upon which we walk, in fact in or upon almost everything we touch or with

which we come in contact, the question why bacteria do not oftener enter the body tissues would seem to be more rational than why they sometimes do so enter. Fortunately most germs are harmless, but many are capable of producing the most severe forms of disease. There are constantly present in the mouth, nose, and upper air passages, as well as throughout the entire gastrointestinal canal, microorganisms which under ordinary conditions are perfectly harmless. Then, too, the body is so built as to offer very powerful resistance to the entrance into it of most germs. First in importance of the body defenses against germ invasion is the skin. The unbroken skin offers an almost impassable barrier to the passage of most forms of germs. Being the most exposed, it is also the strongest of the body defenses against the entrance into it of microorganisms. Few, if any, germs have the power to penetrate it, if healthy and intact. Any person accustomed to dissecting, operating, or performing autopsies with ungloved hands, noting with what impunity highly infectious material may be handled provided there is no broken surface, and how serious are often the results of an overlooked wound or a chance scratch, realizes the importance of the skin as a protection against germs. There are, however, certain normal openings in the skin. These are: (a) those of the digestive tract—the mouth and anus. . . . with the stomach, rectum; (b) the respiratory tract, the mouth and nose—leading into the larynx, trachea, bronchi, and lungs; (c) those of the genitourinary tract, the urethra and vagina—leading to the bladder, ureter, kidney, uterus, and Fallopian tubes; (d) the eye. These openings and tracts are lined by mucous membranes which may be considered as forming a second line of defense against germ invasion. Being less exposed than the skin, the mucous membranes are also less resistant than the skin to the entrance of germs. Indeed, to certain species of germs the mucous membranes are especially susceptible; as the mucous membrane of the intestine to the bacillus of typhoid fever, that of the respiratory tract to the diphtheria bacillus and to the bacillus of pneumonia, and that of the genitourinary tract to the gonococcus. To a great many of the most dangerous species of germs, however, the healthy mucous membrane, like the unbroken skin, presents an impassable line of defense. Nor is the body helpless against the activities of germs even after they have entered its tissues. While the lymphatic system often furnishes the channels by means of which germs are carried from one part of the body to another, the lymphatic glands themselves undoubtedly act as filters arresting the progress of the germs, while the lymph cells probably possess certain germ-destroying powers. Then, too, the white corpuscles of the blood are endowed with properties which enable them to take up germs and destroy them. It is largely for this purpose, in all probability, that the white blood corpuscles leave the vessels and pass out into the surrounding tissues in inflammatory conditions. Certain other cells probably possess this same power of destroying germs. Such cells are known as *phagocytes*, and the process of germ destruction by them is called *phagocytosis*. There are also developed in the body during the progress of germ infections certain substances which appear to be in solution in the

DISEASE GERMS

1. GONOCOCCUS In Pus Cells (Jenner Stain; F. C. Wood).
2. BACILLUS KLEBS-LOEFFLER OF DIPHTHERIA (Sulphuric Acid; Iron Alum, Haematoxylin; Leaming).
3. BACILLUS TYPHOSUS with Flagella (Van Ermengen's stain).

4. BACILLUS TUBERCULOSIS in Sputum (Eosin, Methylene blue).
5. STREPTOCOCCUS PYOGENES in Chains (Sulphuric Acid, Iron Alum, Haematoxylin; Leaming).
6. PNEUMOCOCCUS in Capsules (Copper Sulphate Method of Hiss).

fluids of the blood. These substances are known as antitoxins (q.v.) and have a distinctly inhibitory effect on the further development of the germs.

The effects upon the body mechanism of the activities of disease-producing germs vary, of course, greatly for the different germs. Certain general modes of action may, however, be mentioned. 1. The direct (usually local) effect of the presence of the germs. Thus, in diphtheria the direct local effect of the germ in the throat is death of parts of the mucous membrane and the formation of what is known as a false membrane. In a similar manner the ulcers in the intestines in typhoid fever are due to the direct local action of the typhoid bacillus. Another local effect which germs may sometimes have consists in the formation of infectious emboli in different parts of the body. Thus, e.g., in infectious endocarditis with bacterial growth in the heart valves, a little mass of bacteria may become detached and carried through the circulation until it reaches a vessel too small for it to pass through. Here it stops, forming an infectious embolus and thus setting up a new focus of infection. 2. The production of toxins (q.v.). These are poisons produced in the body by the activities of bacteria. They seem to be largely present in the plasma of the blood and are consequently distributed throughout the body. It is to these toxins that the systemic symptoms of an infectious disease are due, e.g., the fever, prostration, delirium, etc. These toxins differ for different bacteria, a particular toxin probably being specific for each species of germs. That a disease may be accepted as positively proved to be of germ origin, it must fulfill certain very rigid conditions. One single species of germ must always be found present in the diseases. This germ must not be found regularly in connection with any other disease. It must be possible to cultivate this germ artificially and to separate it in what is known as a pure culture, i.e., a growth of this germ absolutely free from any other living substance. It must be possible to induce the same or a similar disease in animals by injecting them with this pure culture. Comparatively few diseases as yet fulfill all of these requirements. Among the most important of the diseases which have been proved to be of germ origin may be mentioned anthrax, actinomycosis, Asiatic cholera, bubonic plague, acute cerebrospinal meningitis, diphtheria, erysipelas, glanders, gonorrhoea, influenza, leprosy, malaria, pneumonia, relapsing fever, syphilis, infantile spinal paralysis, tetanus, tuberculosis, and typhoid. Of the more important of the diseases which from their behavior are believed to be of germ origin, but in which the germs have not as yet been found, are hydrophobia, measles, scarlet fever, small-pox, typhus, a

Bacteriologic T. A. many cases of disease a species of bacteria present may be made by means of a bacterial examination of material during life. This is done in three ways: first, by cover-glass preparation; second, by culture; third, by animal inoculation. In some cases a little pathological material may be obtained on a sterilized platinum loop; in others a piece of absorbent cotton wound about a stiff wire and forming a "swab" is used, by means of which pus or exudates may be obtained and transported in a sterile test tube into which the

swab is thrust; in still other cases fluid material may be obtained by aspiration. A cover-glass preparation is thus made: A very small amount of material is smeared over a cover glass in such a way as to leave streaks of it and not a continuous layer. After being dried by being held in the fingers, charged side uppermost, over a Bunsen burner, it is passed rapidly three times directly through the flame of the burner by means of a forceps, to "fix" it. The cover glass is then held in the grasp of the forceps, charged side up and level, and the chosen staining fluid is dropped on it from a dropping bottle till it is completely covered. The cover glass is then heated over the flame and washed in water, and any other necessary processes are concluded, according to the method of staining employed. The cover glass with the charged side down, and wet thoroughly with water, is placed on a microscopic slide, and the excess of water is removed by means of filter paper in the usual way. An oil-immersion lens is then used, for examination of the specimen.

Culture mediums differ in different cases. Potato, agar-agar, litmus milk, glucose agar-agar, and glucose gelatin are used; but the best culture medium for general purposes is coagulated blood serum. At the slaughterhouse blood is obtained as it runs from the vessels of the beeves, preferably that which flows from the carotid artery, as it clots more quickly. The jar in which it is received is left in a cool place for 24 hours. After a few hours the clot is gently loosened from the sides of the jar, to facilitate its contraction, and after this the jar is not agitated. After about 24 hours the serum is removed with a pipette. Three parts of blood serum and one part of glucose bouillon are mixed to form the culture medium, which is run into test tubes in small quantities. The tubes are placed in a tilted position in the hot-air sterilizer, and when withdrawn the serum is found to be coagulated in a slanting position. Material obtained on a "swab," e.g., from the throat of a suspected diphtheria patient, is lightly smeared over the whole exposed surface of the blood serum in a culture tube. The culture tube is then placed in an incubator or thermostat, and the bacteria are allowed to grow on the nutrient surface, for subsequent examination with the microscope.

Animal inoculations are made as follows: A small piece of suspected material may be inserted under the skin of a mouse by means of a platinum wire, or a little fluid may be injected under the skin of a guinea pig or rabbit. After the death of the animal an autopsy is made, and various organs and tissues are examined microscopically.

Special Examinations. In examining sputum for tubercle bacilli, a cover-glass preparation is made from a dense grayish-white particle taken from the morning sputum. The tubercle bacillus is a slender rod varying from 1.5 micromillimeters to 4 micromillimeters in length, and about 0.4 micromillimeter in breadth, generally slightly curved. The bacilli occur singly, though in cultures they are sometimes found in chains of four to six links. Clublike forms and branches have been seen also. It must be differentiated from the smegma bacillus and others. In examining for the bacillus of diphtheria a blood-serum culture tube is inoculated by means of a swab with exudate from the tonsils of the patient and is placed in the incubator for about

15 hours. The resulting growth is mounted on a slide and examined with a high-power lens. The bacilli will be found to be of varying size, from 1 to 6 micromillimeters long and 0.5 to 1 micromillimeter broad, straight or slightly

SPUTUM CONTAINING TUBERCLE BACILLUS ($\times 1000$).

curved, with rounded ends, singly or in pairs. For the detection of the plasmodium of malaria, a fresh specimen of blood is taken from the lobule of the ear, spread on a cover glass, and inverted on a slide so as to spread the specimen evenly. Fixation may be secured by heating, or by immersing in a mixture of absolute alcohol and ether. The preparation is stained to secure contrast between the parasite and the blood disks. Under the microscope the plasmodia appear about the size of red blood corpuscles, discoid, star-shaped, in odd forms with prolongations, flagellae, and branches, nucleated, granular, etc. If not fixed, the parasites show rapid amoeboid movements in a fresh preparation. Other micro-organisms are described under the

DIPHTHERIA BACILLUS FROM TRACHEA ($\times 500$).

titles of the diseases they cause. Consult: Friedländer, *Mikroskopische Technik* (Berlin, 1900); Thoma, *Lehrbuch der pathologischen Anatomie*, trans. by Bruce (London, 1896); Abbott, *Principles of Bacteriology* (Philadelphia, 1909); Mallory and Wright, *Pathological Tech-*

nique (ib., 1913); Sternberg, *Bacteriology* (New York, 1901); Newman, *Bacteriology and the Public Health* (Philadelphia, 1904); Muir and Ritchie, *Manual of Bacteriology* (New York, 1913); Ball, *Essentials of Bacteriology* (Philadelphia, 1913). See BACTERIA; MICROSCOPY; MALARIA.

DISEASES OF ANIMALS. In the general discussion of the diseases which affect animals various systems of classification have been adopted by different writers. The scheme here presented is that most commonly adopted. Animal diseases may be grouped under the following five heads: (1) infectious; (2) poisoning; (3) constitutional; (4) organic; and (5) diseases caused by animal parasites. Infectious diseases are due to the action of minute organisms in the blood or vital organs and tissues. Such diseases may be communicated from one animal to another by means of infected blood, by tissues, or by animal secretions containing the disease-producing organism.

The most important infectious diseases of animals are abortion, actinomycosis, contagious agalactia, anthrax, asthenia, blackleg, braxy, cattle plague, cerebrospinal meningitis, dog distemper, foot-and-mouth disease, fowl cholera, glanders, hog cholera, influenza, contagious pleuropneumonia, rabies, roup, swine plague, tetanus, Texas fever, and tuberculosis. Each of these is discussed in a separate article.

Under diseases of poisoning are included cases of poisoning of an acute or chronic nature by mineral, plant, or animal poisons. The more common mineral poisons to which animals may gain access are compounds of arsenic, lead, copper, zinc, phosphorus and mercury, mineral acids, and caustic alkaline substances. Among plant poisons mention may be made of strychnine, opium, aconite, and various wild plants, such as water hemlock, larkspur, loco, veratrum, death camas, and lupine. The eating of large quantities of ergot produces the symptoms of ergotism (q.v.). Smuts and molds sometimes cause digestive disturbances of a more or less serious nature. Animal poisons include snake poison, bee stings, stings of certain other insects, arachnids and nematodes, such as the buffalo gnat, ticks, ascarids, etc.

Diseases caused by animal parasites include those which are produced by parasitic worms, insects, mites, etc. Every species of domestic animals is infested to some extent with parasitic round or flat worms. The lung and stomach worms (q.v.) of sheep are periodically the cause of great losses to the sheep industry. The fluke-worm, which causes liver rot (q.v.) of sheep and other animals, is of great economic importance. The nodular disease of fowls is due to the presence of tapeworms in the walls of the intestines. Trichinosis of hogs is due to infestation by the round worm (*Trichinella spiralis*). Beef and pork measles are conditions produced by the presence of tapeworms in an immature condition in the meat. The kidney worm, which usually lies imbedded in the fat tissue of the loins of hogs, occasionally penetrates the kidney and causes death. Besides the examples already given, there is a considerable variety of round and flat worms which infest the intestines of domestic animals without causing any marked disturbance except when present in unusually large numbers.

Nearly all domestic animals are subject to mange or scab. This disease is due to the at-

tacks of various species of mites. One species with several varieties causes one form of scab on sheep, cattle, horses, and goats. A few species of flies live, during a portion of their life cycle, as parasites on or in animals. Chief among these are the horse botfly, sheep botfly, ox warble fly, and screw-worm fly. The last three occasionally cause serious disease. Others, such as the stable fly, horn fly, and tabanids, are a source of great irritation and annoyance as well as of depletion through the removal of blood. Various species of ticks and fleas are well-known pests on domestic animals. Many parasites are of primary importance because of their agency in the transmission of disease-producing micro-organisms, either by mechanical conveyance or through serving as an intermediate host in which some development of the disease-producing agent takes place. Important among such parasites are the ticks, which are true intermediate hosts of the Texas fever and other organisms, and certain flies which convey trypanosomes which cause surra and other diseases.

Under the head of constitutional diseases reference is ordinarily made to such pathological conditions as anæmia, scurvy, and diabetes, which occasionally prevail in animals as well as in man.

The term "organic diseases" includes diseases of the skin, digestive organs, respiratory organs, circulatory organs, nervous system, and urogenital organs. Some of the numerous diseases which fall in this category are infectious.

It will be understood that the system of classification here proposed cannot be followed too strictly and that the different categories are not mutually exclusive. The various forms of scab and itch may readily be transmitted from one animal to another by contact and are therefore contagious. The terms "infection" and "contagion," however, usually have reference to diseases which are due to the action of bacteria, protozoa and filterable viruses. Of the chief infectious diseases of animals, actinomycosis, anthrax, glanders, foot-and-mouth disease, rabies, tetanus, and tuberculosis may be transmitted to man. Consult: N. S. Mayo, *Diseases of Animals* (5th ed., New York, 1910); J. Law, *Text-Book of Veterinary Medicine*, 5 vols. (Ithaca, N. Y., 1905-11); E. W. Hoare, *A System of Veterinary Medicine*, 3 vols. (Chicago, 1913); Huttyra and Marek, *Special Pathology and Therapeutics of the Diseases of Domestic Animals*, 2 vols. (New York, 1913).

DISEASES OF PLANTS. In addition to being of great scientific interest, diseases of plants are of immense economic importance. Losses running into millions of dollars have been caused in different countries by certain plant diseases. In Australia the wheat rust often greatly depreciates the wheat crop; phylloxera has ravaged the vineyards of France; potato rot is held partly responsible for some of the famines in Ireland; mildew and black rot are serious enemies to grape culture in America, and in parts of California grape growing has been abandoned on account of disease. While the occurrence, though not the causes, of many plant diseases has long been known, their definite study (phytopathology) has been developed since about 1885. Since that date our knowledge of the causes of diseases and of the means of preventing them has been growing with remarkable rapidity, and no country has added more to this information than the United States,

through the plant pathologists of the Department of Agriculture and of the several agricultural experiment stations.

For ordinary purposes, plant diseases may be classified, according to their causes, into four categories, viz.: (1) those caused by fungi; (2) those caused by bacteria; (3) those due to nematodes and insects; and (4) those due to physiological causes.

Taking these in the order of enumeration, the diseases due to fungi are given first rank, and they are perhaps the most widely spread and destructive of all. There is hardly a crop or a species of plant that is not liable to attacks of fungi through either its roots, stem, leaves, or fruit. The spores of fungi are exceedingly minute, and through them disease is spread. They are carried everywhere by the wind, by insects, and other means. Finding lodgment upon a plant, if the conditions are favorable, it is attacked. Plants not in perfect physical and physiological condition offer an easy entrance to the germ tube sprouted from the spore, and the threadlike mycelium spreads the disease through the host plant, as it is called, the fungus being referred to as a parasite. All plants are not subject to the attack of the same fungi, since certain conditions render a given plant immune to some and susceptible to others; nor are all fungi parasitic, since some live usefully as saprophytes upon dead and decaying vegetation. Some fungi gain entrance to plants by sending their germ tubes through the minute breathing pores of the leaves; others dissolve their way through the cuticle by means of ferments which they secrete. Still others known as wound fungi can gain entrance only through some wound on the host plant, entrance having to be prepared for them. Once the host is attacked and the conditions of temperature and moisture favorable, the disease progresses with great rapidity, from individual to individual, and becomes a veritable epidemic. The host plant is injured in a number of ways, such as being robbed of its nourishment, having its water supply shut off, etc. Some parasites stimulate the host to unusual growth, as may be seen in the galls, knots, and other swellings of which are of grotesque shapes. Others produce stunted growth or destroy the host plant entirely. Many fungi which cause plant diseases are interesting on account of the fact that they exist in two forms, each of which lives upon a different plant. The phases which belong to one cannot be made to grow upon the other, but the phases of each host readily inoculate the other. This is true of the fungus causing apple rust, the alternate form of which is found in the so-called apples of the red cedar or juniper. Different stages of one of the wheat rusts (*Puccinia graminis*) are found upon wheat and upon the barberry leaves. A disease of pine occurs in another form upon currant leaves, and many other similar examples are well known. Familiar examples of disease caused by fungi are the rusts and smuts of grains, potato rot, grape rot, clubroot, crown gall, plum knot, anthracnose of many plants, leaf spots, wilt diseases, mildews, scab, etc., all more fully described under the names of their respective hosts.

The second class of plant diseases to be considered are those due to bacteria, over some of which there has been considerable controversy. Some writers have denied their bacterial origin, but the investigations of Dr. E. F. Smith and

others seem to prove that in a number of well-known instances bacteria are the immediate cause of disease. These investigators by carefully conducted experiments have succeeded in producing the diseases in question by inoculation experiments with the bacteria. Diseases of fungus origin for the most part attack certain definite portions of plants, as the leaves, fruits, etc., destroying them and indirectly the rest of the plant; but the bacteria, especially upon soft, herbaceous plants, attack any part of the plant and cause its sudden collapse without much delay. Prominent among the diseases attributed to bacteria may be mentioned the fire blight of apples and pears, crown gall of many plants, black rot of cabbage, a wilt disease of cucumbers and melons, a brown rot of potatoes, eggplant, and tomatoes, a disease of sweet corn, a hyacinth disease, and a disease of celery. Most of these are fully characterized under their special names.

Among the diseases of the third class may be mentioned the phylloxera, which attacks the roots of the grape, devastating the vineyards of France, Italy, Germany, and Europe generally, wherever varieties of grapes which belong to *Vitis vinifera* are grown; nematodes, or eelworms, which attack the roots of many plants in parts of the United States, Europe, and elsewhere, causing galls to be formed to the great detriment of the plant; and thrips and aphides, whose punctures cause a disease of carnations and doubtless many other plants.

The diseases of the last class are due to some interference with the proper exercise of the functions of the plant—by improper nutrition, too much or too little water, light, heat, etc. These functional diseases manifest themselves in a manner similar to the bacterial diseases, the whole plant being affected. For these diseases the corrective means suggest themselves, the only discovery of the causes.

The progress of the past few years have led to the discovery not only of the causes of many plant diseases, but also of the means whereby they may be prevented. Cures are not known for such diseases when the plant is once badly affected, so attention is given to their prevention. Sanitary conditions are necessary to keep plants in a healthy state. In order to prevent the spread of plant diseases all affected plants and parts should be collected and burned. All weeds and wayside plants likely to harbor the disease should be destroyed. Many diseases are spread by insects, and, as far as possible, these should be destroyed. Many diseases may be prevented by the use of fungicides and repeated spraying of the plants with fungicides (q.v.). The theory upon which these are used is that the copper or other substances used are detrimental to the germination of the fungus spores by which the diseases are spread. Experience has shown that much of the loss due to some of our most common and destructive plant diseases might have been absolutely prevented by the timely and thorough use of fungicides, and that at a cost very small indeed compared to the loss sustained.

DISENTIS, dē'zen-tis. A village in Switzerland, Canton Grisons, situated 34 miles southwest of Chur and 3600 feet above sea level (Map: Switzerland, C 2). It is the site of a large Benedictine monastery, founded in 614 by the Scottish monk Sigisbert. Pop., 1900, 1400; 1910, 1691.

DISFRANCHISEMENT. See SUFFRAGE.

DISHONOR (ML. *dishonor*, from Lat. *dis*, apart + *honor*, honor) OF NEGOTIABLE PAPER. The refusal or failure of the drawee of a bill to accept, or of the acceptor of a bill or the maker of a promissory note to pay it at the proper time. If the drawee of a bill of exchange refuses to accept it when duly presented, the holder is bound to give notice at once to the drawer and indorsers, or he will relieve them from liability on the paper, as a rule. Ordinarily the drawer of a bill of exchange or a check has funds in the drawee's hands, upon which the bill or check is drawn, and if the drawee refuses to honor the bill or check, the drawer is entitled to notice, so that he may withdraw his funds. If a banker dishonors a customer's check by refusing to pay it when the customer's account is good for it, he makes himself liable in damages to the customer, for such an act tends to harm the latter's credit. See NEGOTIABLE PAPER, and consult the authorities there referred to; see also BILL OF EXCHANGE; CHECK; PROMISSORY NOTE; PROTEST.

DISINFECTANTS (from *dis*, without + Eng. *infect*, from OF., Fr. *infecter*, from Lat. *inficere*, to infect, from *in*, in + *facere*, to make). A class of substances which have the power of destroying the causes of infectious and contagious diseases. In a large proportion of these diseases the causes have been found to be microorganisms of a vegetable nature, called bacteria (q.v.). In the rest of these diseases such microorganisms are supposed to exist, but have not yet been identified. Disinfectants are used to destroy these germs or to stop infection. The term "deodorants" is applied to substances that dissipate or destroy foul smells, but do not necessarily destroy germs; and the term "antiseptics" is applied to substances that prevent the growth especially of those bacteria which cause fermentation or putrefaction of dead tissue, or suppuration in the living body. A disinfectant may act in one of several ways. It may oxidize the offending material, or neutralize the activity of the latter by albuminous combination, or it may alter the reaction of the surrounding media, rendering it unfavorable for the development of germs.

All clothing and bedding, curtains, carpets, etc., which cannot be burned immediately and which ought to be disinfected should be kept

moist until completely sterilized, for the bacteria and their spores are easily scattered in the dust arising from handling dry articles. The mucus coughed up by tubercular patients readily pulverizes and mixes with the dust when dry, thus endangering any one who may inhale the dust-laden air of an infected room. All dust which has settled in cracks, on woodwork or furniture of an infected room, should be removed by wiping it up with cloths wet with a solution of bichloride of mercury and water, 1 to 1000, or a 3 per cent solution of carbolic acid in water; and the cloths should be burned afterward. The same solution may be used in washing all walls and woodwork. Boards of health advise that apartments, after being thus treated, should be fumigated with sulphurous acid, that all cracks may be thoroughly permeated by a disinfectant. For each 1000 cubic feet of space four pounds of sulphur is placed in an iron pan, which is placed upon a brick, which, in turn, stands in a tub of water. Vessels of boiling water are placed about the room. The sulphur is then lighted and the room closed air-tight. This method may have some value in cases of smallpox, scarlet fever, and measles, but it does not kill the germs of diphtheria, anthrax, or tuberculosis, and is being abandoned. Formaldehyde gas has been employed increasingly as a disinfectant since 1893, as generated by special apparatus from formalin pastilles. Two grams of formalin for every 35 cubic feet of room space has destroyed anthrax, tubercle, diphtheria and typhoid bacilli, streptococcus, and other bacteria in a few hours. Formaldehyde does not injure clothing, fur, paper, leather, photographs, or rubber or metal goods. Sanitarians advise the disinfection of dwellings, carpets, bedding, clothing, and upholstery with formaldehyde, and advocate this agent for disinfection of ambulances and other conveyances which can be tightly closed, the gas to be used in the proportion of 10 per cent by volume, the time of the exposure to be not less than one hour.

Surgeons' instruments are disinfected (or, rather, sterilized) by boiling them in water containing 2 per cent of bicarbonate of soda, by passing them through the flame of an alcohol lamp just before use, or by exposing them to formaldehyde gas. The latter does not dull keen edges. Surgeons' hands and arms are sterilized by washing with soap or green soap and nail-brush, and then with a solution of permanganate of potash or of bichloride of mercury. The faces of typhoid and cholera patients, and the sputa of patients suffering with tuberculosis, influenza, pneumonia, etc., should be disinfected with a 5 per cent solution of fresh chloride of lime or a 5 per cent solution of crude carbolic acid. Either of these disinfectants is useful in disinfecting privy vaults or accumulations of sewage. Peroxide of hydrogen is used in disinfecting suppurating wounds in some cases. Chloride of zinc and chlorine gas, as well as certain patented coal-tar derivatives are used in special cases for disinfection.

Heat and Cold. It must be remembered that the best disinfectant of all is heat. Articles of clothing that can be washed are easily disinfected by the use of boiling water. Other articles may be subjected to baking, or to sterilizing by the use of steam under pressure. Ovens called sterilizers are arranged in hospitals, into which steam at a temperature of about 225° F. is admitted under pressure for the treatment of

clothing and bed coverings. Similar cylinders are constructed for the use of health departments in large cities. Cold kills the bacteria of yellow fever, but not those of anthrax, smallpox, or typhoid fever. Consult Rosenau, *Disinfection and Disinfectants* (Philadelphia, 1902), and Christian, *Disinfection and Disinfectants*, trans. by Salter (London, 1913). See ANTISEPTIC; BACTERIA; CONTAGION; INFECTION; DISEASE, GERM THEORY OF.

DISINFECTION. See DISINFECTANTS.

DISK (Lat. *discus*, Gk. *δίσκος*, *diskos*, disk). A word of various application among plants. Among Compositæ (sunflowers, asters, etc.) it refers to the central part of the head in which the showy corollas do not occur as at the margin. In other groups it refers to a ringlike structure developed within the flower, from which certain of the floral parts often arise; or to a disklike structure upon the top of the ovary in certain epigynous flowers. See FLOWER.

DISKO. See DISCO.

DISLÈRE, de'slâr', PAUL (1840-). A French engineer and administrator, born at Douai. He studied at the Ecole Polytechnique and in 1861 entered the naval engineers. In 1888 he became an engineer of the first class. From 1868 to 1871 he was in charge of the arsenal at Saigon, French Indo-China; in 1881 was appointed Councilor of State; and in 1882 received the post of Colonial Director in the Ministry of Marine. He was transferred in 1891 to the directorship of foreign commerce. He was one of the presidents of the Universal Exposition in 1900. His *Traité de législation coloniale* (1886) is regarded as authoritative. His works further include: *La guerre d'escadre et la guerre des côtes* (1876); *Etudes de statistique*; *Les budgets militaires de la France et de l'Angleterre* (1878); *Le service militaire aux colonies* (1889; 1899).

DISLOCATION (Fr. *dislocation*, from ML. *dislocare*, to dislocate, from Lat. *dis-*, apart + *locare*, to place, from *locus*, place). A displacement of one bone from another with which it forms a joint ("put out of joint" being the popular expression). Dislocations are generally the result of accident, but may also be the result of disease or may be congenital. The displacement may be partial or complete. In the former their cases into simple and compound. In the former the skin remains unbroken, and compound when there is a wound by which the external air may communicate with the joint. Occasionally, in addition to the dislocation, there are fractures of the bones, or lacerations of important blood vessels in the joint. In the former the dislocation is then said to be compound. Dislocation is rare in infancy and in old age; in the former the joint ends are very flexible and yield to violence, while the aged skeleton is so rigid that the brittle bones fracture under force that would drive the younger and firmer ones out of their sockets. Dislocations are most frequent between 30 and 60. Persons with weak muscles and lax ligaments, or those in whom the latter have been softened by inflammation of the joint, are predisposed to dislocation. The joints most frequently displaced are the shoulder and the elbow.

General Symptoms. After a blow, fall, or violent muscular exertion, a limb is found to be immovable at the injured joint; there is great pain, and the shape of the part is changed; but soon swelling ensues, and every distinctive mark

about it is obscured. If left alone, or merely treated as an inflamed joint, the swelling gradually subsides, but the immobility continues, the limb is crippled for months or years, until nature forms a new socket for the end of the bone.

Treatment. This consists in reduction or replacement of the bone into its original position. Its return is opposed by the muscles attached to it, which are stimulated to contraction by the pain of the operation, the latter requiring at times the application of considerable force. Reduction is accomplished by two methods—manipulation and traction. In the former the surgeon endeavors first to relax those muscles which prevent the return of the head of the bone into its proper position, causing the bone to retrace the path by which it escaped from the socket. When manipulation is unsuccessful, the attempt is made to overcome the resisting power of the muscles by traction. When this is fully done, the bone usually slips easily into its place, with some guidance from the hand of the surgeon. Violence in traction, however, must never be used, as injury to surrounding tissues, or fracture, may result. In some cases anæsthesia must be resorted to in order to produce complete muscular relaxation.

The subsequent treatment consists in rest, with splints or bandages to prevent a recurrence of the dislocation while the rent in the joint capsule is healing. Four to six weeks are usually necessary for the accomplishment of this process. The treatment of congenital and pathological dislocation is palliative and requires the use of some special apparatus, although at times operation may give a new and serviceable joint.

DISLOCATION (IN GEOLOGY). See FAULT. **D'ISLY, DUC.** See BUGEAUD DE LA PICONNERIE.

DISMAL SWAMP. A swamp having an area of about 750 square miles, lying chiefly in Virginia and partly in North Carolina (Map: Virginia, H 5). Approximately in its centre is Lake Drummond, about 2 miles in diameter, very shallow and lying about 10 feet above the level of the Elizabeth River at Norfolk, Va. Elsewhere the surface is covered with tangled weeds and heavy timber, with a thick undergrowth. A canal crosses the swamp, opening . . . between Elizabeth City, N. C., and . . . , thus permitting vessels to pass between Albemarle Sound and Chesapeake Bay. Much of the swamp's area has been reclaimed. The area was originally about 2200 square miles but has been reduced by drainage and cultivation to that above named, 750.

DISMANTLED (from *dis*, without + *man-tle*). The state of a ship when unrigged and after her guns, stores, etc., have been taken out. When men-of-war were built of wood, they were, if not recommissioned, after completing a cruise, dismantled; in that condition, with hatches and other openings closed, they were secured alongside a navy-yard wharf, and this was called being laid up *in ordinary*. Modern ships are not dismantled, except for repairs. They deteriorate very much faster than wooden ships, and it is vastly more expensive to dismantle and reëquip them.

DISMAS, SAINT. The name which tradition has attached to the one of the two malefactors crucified on either hand of Jesus who repented. He is represented with a cross beside him. The impenitent malefactor is called Gesmas. Both names are highly improbable.

DISON, de'zôn'. A town of Belgium, in the Province of Liège, situated about 2 miles north west of Verviers, on a railway line. It has extensive woolen and cotton mills and stone quarries. Pop., 1900, 12,355; 1910, 11,434.

DISOWNED, THE. A novel by Bulwer-Lytton (1829).

DISPART' (from Lat. *dispartire*, *dispartire*, to divide, from *dis*, apart + *partire*, to divide, from *pars*, part). The difference between the semidiameters of the parts of the gun on which the sights are placed (if on the gun itself). The term is practically obsolete, as sights are now placed on the mount and not on the gun, but it was formerly of great importance.

DISPENSARY (Fr. *dispensaire*, from ML. *dispensarius*, from *dispensa*, larder, from Lat. *dispensare*, to disburse, from *dis*, apart + *pensare*, frequentative of *pendere*, to weigh). An institution in which medical or surgical treatment is given free of charge to patients who are able to walk in and then return home, no beds being provided as in a hospital. In 1687, at a meeting of physicians in London, England, it was resolved to supply the poor with medicines at certain fixed prices. Previous to this, aid and medical treatment were given to the poor at the houses of wealthy people or at monasteries. In 1696 the president, censors, and 50 members of the Medical College of London agreed to maintain a dispensary that should give medical aid to all who asked it, and a building was erected for the purpose, with rooms for seeing patients and dispensing medicines. Physicians were also appointed, who visited the sick poor in their homes. This building, the Royal General Dispensary, Bartholomew Close, London, was opened in 1770. The oldest dispensary in the United States, the New York Dispensary, was founded in 1790. In all cities and large towns in the Union dispensaries exist, supported by private charitable organizations or maintained as "outdoor poor" departments of county, city, or private hospitals. In some cases medicines are furnished gratuitously, but in most dispensaries in cities a charge of 10 cents is made for each medicine prescribed.

Dispensary Abuse. In all the large cities a great number of well-to-do people seek free medical aid. The blame for this condition appears to lie at the doors of the trustees and superintendents of the clinics and dispensaries, and sometimes at the doors of the physicians who practice in them. The college clinic is established for the purpose of securing material with which to illustrate the didactic lectures delivered by the professors and with which to teach medical students the appearances and conditions of disease. To give free medical aid to the poor is a secondary consideration. The applicant for free treatment at a college clinic or at a dispensary where the attending physician is allowed to teach private paying pupils with the illustrative aid of the patients, is quite as often admitted in silence as he is questioned about his ability to pay a fair fee for a physician practicing near his home. If the patient is asked, the patient is not always truthful, and it is a matter of common occurrence for patients to wear old clothing and give fictitious names and false addresses in order to avoid paying a physician the fees they are quite able to afford.

In accordance with a law passed April 18, 1899, a new régime was initiated in New York City on October 1 of that year. Since that date

each dispensary must be licensed by the State Board of Charities, and each applicant for a license must take oath that the dispensary is for the public benefit; no school of medicine is obligatory, but the board is empowered to examine every dispensary and revoke licenses of those not conforming to the law. A dispensary is defined to be any person, corporation, institution, association, or agent whose purpose it is, either independently or in connection with any other, to furnish at any place or places, to persons nonresident therein, either gratuitously or for a compensation determined without reference to the cost or value of the thing furnished, medical or surgical treatment, medicine or apparatus; provided that the moneys used by and for the purposes of the said dispensary shall be derived wholly or in part from trust funds, public moneys, or sources other than the individuals constituting said dispensary. Applicants for aid must sign a declaration of financial inability. Violation of the law is punishable by fine. The college clinics, however, seem to escape the control intended by the framers of this statute, because their purpose is to teach medicine to students. Consult: *Medical Memoir of the Central Dispensary in London, 1773 to 1774* (London, 1774); *A History of the Boston Dispensary* (Boston, 1859), and report of the same for 1911; *New York State Board of Charities: First Report of the Committee on the Abuses of Medical Charity* (New York, 1878), also similar reports for 1897 and 1905; Goldwater, *Dispensary Ideals: A Plan for Dispensary Reform* (Philadelphia, 1907).

DISPENSATION (Lat. *dispensatio*, from *dispensare*, to disburse). A term in ecclesiastical law to denote a relaxing of the law, by a lawful authority, in some particular case; more specifically a license granted by the Pope or some bishop relieving or exempting an individual in certain circumstances from the action of some law or regulation of the Church. In the Roman Catholic church, since at least Innocent III, the principle has been established that only the Pope can dispense from the operation of a universal law; but in certain cases he may depute this power to bishops and others. The dispensations known to the Roman canon law are divided into papal and episcopal, into dispensations of right and of favor, and (according to the public or secret character of the impediment to be removed) *pro foro externo* or *interno*. In cases of dispensation *pro foro externo* the authorization is through the administration bureau known as the Apostolic Dataria; in cases *pro foro interno*, through the Penitentiaria. Bishops may dispense from their own statutes or those of their predecessors; vicars general have the same power as bishops. Parish priests may dispense their own people from observance of fasting, abstinence, and holy days. Henry VIII assumed the ecclesiastical right of dispensation within the realm of England in 1534 and conferred it on the Archbishop of Canterbury in so far as it was not contrary to the law of God. The granting of special licenses for the performance of the marriage ceremony without publication of banns (q.v.) is the only form in which this power is now exercised by the Archbishop. The only form of dispensation now exercised by the bishops of the Church of England is granted to a clergyman to enable him to hold more benefices than one or to absent himself from

his parish. In the Protestant churches on the continent of Europe the right of dispensation from the operation of ecclesiastical law has in theory devolved upon the princes, who, however, generally exercise it through the consistories. See DISCIPLINE, ECCLESIASTICAL; INDULT; MARRIAGE.

DISPERMINE. See PIPERAZINE.

DISPERSAL (from *disperse*, from Fr. *disperser*, to scatter, from Lat. *dispergere*, to disperse, from *dis-*, apart + *spargere*, to scatter). In plants, the scattering of seeds, spores (including pollen grains), and even vegetative members. Hooked appendages, etc., are spoken of as dispersal adaptations. See SEED; POLLINATION; SPORE.

DISPERSE SYSTEMS. See COLLOIDS.

DISPERSION (Lat. *dispersio*, from *dispergere*, to disperse). It was shown by Sir Isaac Newton that, if a beam of sunlight entered a darkened room through a small round opening, *A*, and fell upon a prism of glass, *P*, the light on leaving the prism consisted of colored beams, each beam having a different direction, but merging into its neighbors. In-

DISPERSION — NEWTON'S EXPERIMENT

stead of the beam of light falling on the screen at *BC* and making a bright round white spot, the rays after traversing the prism are divergent and produce the prismatic band seen at *RV*, the violet rays being bent or refracted the most. The colors thus observed form what is called a *spectrum*. (A better is to have as the source of light a to the edge of the prism, a plan also tried by Newton.) White light is thus dispersed into colors. The angle between the beams of any two colors is called the "dispersion" of those colors for the given conditions of material and shape of prism and of angle of incidence. Dispersion is due to the fact that ether waves of different wave numbers—and hence characterized by different colors if they are visible—travel in a material medium, e.g., glass, with different velocities, and therefore have different degrees of refraction. The "dispersion curve" of a given substance is a curve drawn having wave length and index of as abscissæ, showing how these two quantities are connected for the substance. Dispersion may also be caused by various interference and diffraction phenomena. Further, since dispersion is a characteristic of wave motion, the assumption being that some waves travel faster than others in a given medium, it may be observed with all kinds of waves in suitable media. See LIGHT.

DISPLACEMENT (from *displace*, from *dis*, without + *place*, Fr. *place*, from Lat. *platea*,

Gk. *πλατεία*, *plateia*, street). The weight of an object determined by the amount of water it displaces, i.e., the weight of the water displaced. Formerly both men-of-war and merchant vessels were classed according to their tonnage (q.v.) measurement; and the latter still are, but the former are now classed by displacement as well as design. The displacement selected as a standard for each particular vessel is one in which the vessel is said to be at *mean load draft*. In theory it means that the average amounts of coal and other stores are on board; it is a purely arbitrary condition, however. The only condition in which vessels are justly comparable is with all coal and stores on board. In the United States and Great Britain the displacement of a ship is measured in tons of 2240 pounds; in countries using the metric system it is measured in tons of 1000 kilograms, or 2204.6 pounds.

DISPLAYED (from *display*, from OF. *despleur*, *desploier*, Fr. *déployer*, It. *dispiegare*, *spiegare*, from ML. *displicare*, to unfold, display, from Lat. *dis*, apart + *placare*, to fold). A term in heraldry denoting "expanded," and applied, e.g., to an eagle with wings outspread.

DISPOSITION (Lat. *dispositio*, from *disponere*, to dispose, from *dis*, apart + *ponere*, to put). The hypothesis of mental dispositions has been used in psychology to bring mental facts into an interconnected and coherent system. It is obvious that the conditions of many mental processes are not themselves directly accessible to introspection. When, e.g., a name is remembered, it is not always possible to point to the immediate conscious antecedents of the memory. Various hypotheses have been put forward to supply the missing links in the sequence of conscious processes. One hypothesis says that the mind has a "faculty" of remembering (see **FACULTY**); another, that the absent terms are to be explained as physiological factors, which are not themselves accompanied by consciousness, but which introduce conscious processes; a third hypothesis refers the matter to the "subconscious" (q.v.), i.e., to a lower stratum of consciousness, which escapes introspection; and, finally, coherence is brought into mental facts by an hypothesis which posits "mental" or "psychical dispositions." Bain has spoken of "the permanent products stored up in the mental organization" as "stores in reserve," the fruits of experience which may be conceived as lying outside consciousness and yet as affecting mental processes. Such a conception is based upon the fact that past experiences seem continually to color our present thoughts, emotions, perceptions, and actions. I hear a familiar voice, and immediately the face of a friend—as I last saw him, perhaps—comes before my mind. Evidently, if I had had no previous knowledge of the individual, the sound would not have "aroused" the visual image of his face. One may say, in this and similar cases, that the previous experience left a "persistent trace" which serves to revive the image.

The difficulty of the hypothesis lies in its inability to give any descriptive account of the conditions of consciousness which it supposes to exist. If one means by "psychical dispositions" a host of ready-made sensations, ideas, emotions, etc., which are not in consciousness, but which nevertheless exist, one is surely juggling with terms; for consciousness is involved

in the very notion of these processes. If, again, the disposition is neither mental nor material, it can only be an unknown condition which we may call *x*. The "physiological disposition" is therefore the best working concept. Experimental psychology, in investigating the conditions underlying the sequence of conscious processes, recently has found it necessary to speak technically of "tendency," and has thus given the term "disposition" a fairly specific meaning. The tendencies and dispositions are physiological in nature; every sensory or imaginal excitation leaves behind it a "trace" or "impression" in the nervous system, sets up according to its strength and diffusion what is called an "impressionary tendency"; every such excitatory process, moreover, tends to call up other like processes which have been associated to it (the "associative tendency"); and, finally, any particular train of associative tendencies may be guided by a determining tendency (q.v.). A "disposition" may now be described as a general set or state of the nervous system, from and within which both determining and associative tendencies may arise. Let us suppose, e.g., that an artist and a geologist are viewing the same landscape; each has a general disposition, a cortical set, a nervous bias, in part perhaps inherited and in part acquired. Consequently each has a rich field of associative tendencies, some of which we may imagine both men to possess in common, while others are separately conditioned upon the respective dispositions. Moreover, as a more direct result of the dispositions, each has a peculiar set of determining tendencies. The artist has, among others, a determination to paint pictures when they are suggested to him; the geologist, to judge the age of geological formations when some unusual bit of evidence is presented; the perception of a certain combination of color, therefore, may touch off the artist's determining tendency in such wise that he notes the hues and tints, the distribution of light and shade, the contour of the sky line, all in the sense of his particular end, while the same perception arouses in the geologist a determining tendency that culminates in a judgment of the age of the hills in the background. Both disposition and tendencies may, or may not, be represented in consciousness; and both consciousnesses, if present, are subject to the laws of growth and decay.

We have here spoken of disposition and of the various forms of tendency as if they were real characters. So in one sense they are: the nervous system behaves in certain definite ways, which we are in duty bound to recognize and name. But it must be remembered that our knowledge is altogether indirect, drawn from the results of psychological experiments. As to what actually goes on in the nervous system when we speak of disposition, or of associative and determining tendencies, we do not know. The physiological explanation is thus a problem for the future. DISPUTATION (Lat. *disputatio*, from *disputare*, to dispute, from *dis*, apart + *putare*, to think). An exercise of logical and dialectic skill in which one party advances an argument and the other seeks to refute it. Challenges

to such exercises were often issued—e.g., at Paris in 1577 by the “Admirable Crichton.” Memorable religious disputations were those between Knox and Kennedy (1562) and between Laud and Fisher the Jesuit (1623). The practice survives as an academic form in some of the German universities, where the candidate for the doctorate is obliged publicly to defend the thesis contained in his printed dissertation. Formerly this disputation was held in Latin, but in late years this practice has become rare.

DISPUTATION OF BERN. See BERN, DISPUTATION OF.

DISRAELI, dīz-rā'li or dīz-rē'li, BENJAMIN, EARL OF BEACONSFIELD (1804–81). An English author and statesman. He was born in London, Dec. 21, 1804, the son of Isaac D'Israeli, author of *Curiosities of Literature*, who belonged to a Jewish family. His education was carefully superintended by his father. In 1821 he was articled to a solicitor with a view to a government office, but, finding the study of the law unattractive, he withdrew his name from Lincoln's Inn in 1831. He had meanwhile become famous as an author, having published his book *Vivian Grey* in 1826. He continued his literary career and spent three years (1828–31) traveling in Spain, Italy, and the Levant. He was, however, more ambitious for political than for literary celebrity, and, after two unsuccessful attempts to enter Parliament as a Radical, he succeeded in entering as a Tory from Maidstone in 1837. Before this time his political pamphlets, especially his *Vindication of the British Constitution*, which Peel commended, had attracted wide attention. In the House his maiden speech was so much in the grand style and delivered with so many extravagant gestures that it excited ridicule. Much disconcerted, Disraeli stopped abruptly, making, however, the prophetic remark, “I shall sit down now, but the time is coming when you will hear me.” From this time on he studied carefully the style of successful parliamentary orators and propagated his political tenets in his novels, *Coningsby* (1844), *Sybil* (1845), and *Tancred* (1847). Looking towards the Stuart monarchy for inspiration, he held that the government from 1688 to 1832 had been a Whig oligarchy, and that now the crown, released by the Reform Bill, might regain some of its powers, thereby solving many modern political and social problems. This idea, plus his Semitic ideals, was a tenet of the Young English party, of which he became the leader. In 1843 the landed aristocracy and country gentry found in him a spokesman for the dissatisfaction with which they regarded the threatened relaxation of the protective system. In 1846 he made a most bitter attack on Peel in the debate on the repeal of the Corn Laws, and on the death of Bentinck, in 1848, he became the acknowledged leader of the Protectionist party in the Commons. He bore generous testimony to the worth of his predecessor in his *Lord George Bentinck: A Biography* (1852). The same year the Earl of Derby offered him the post of Chancellor of the Exchequer, a position which he held with honor and credit. Seeing that the nation now desired free trade, he coolly discarded protection. His second budget was, however, rejected by the Commons, and the cabinet resigned in December, 1852. Disraeli did not resume his position until the

second Derby ministry (1858). One of his greatest disappointments was Derby's refusal to form a ministry with the aid of the Peelites in 1857, as Disraeli thought the country ready for his favorite reforms. There was but a scanty majority for the ministry of 1858, and in 1859 Disraeli's reform measure, the weak “Franchise” Bill, was rejected.

During the seven years of Liberal rule that followed Disraeli had to contend not only against the popularity of Lord Palmerston, but against suspicion and dissatisfaction in his own party. His talents, spirit, and persistency were so great during this trying time that he won admiration from all, even from his opponents. When Derby returned to power in 1866, Disraeli again became Chancellor of the Exchequer, and the most influential member of the new ministry. It was owing to him that the Conservatives now passed the famous Reform Act of 1867, which offered a far wider franchise than any previous law. In this way Disraeli hoped to outbid the Liberals, and seemingly he triumphed, succeeding Derby as Premier in 1868, only to be turned out of office one year later by a general election.

In 1874 he returned to power with a safe Conservative majority for the first time in his career. Although his ministry assured many useful reforms, like the different factory acts, the poor-law amendment, and the artisans' dwelling acts, it became famous chiefly through its foreign policy, conducted by the strong hand of Disraeli himself. His policy was aggressive and essentially imperial. He acquired control of the Suez Canal, interfered in Afghanistan to thwart Russia, and in 1877 proclaimed the Queen of England Empress of India. He called a halt to the Russian advance upon Constantinople in 1878, sending a British fleet to the Dardanelles and a division of the India army to Malta, and proudly declared on his return after making the Treaty of Berlin that he brought peace with honor. In Africa the Transvaal was annexed and the power of the Zulus broken. In 1880, however, his ministry was overthrown. His health had ere this required him to withdraw from the leadership of the House of Commons, and in 1878 he had entered the House of Lords as the Earl of Beaconsfield. On April 19, 1881, he died in London.

From whatever standpoint we view Beaconsfield's career, we cannot but be struck with wonder. That a Jewish novelist should become the acknowledged champion of the British aristocracy seems past all belief. His statesmanship was of a high order. The Empire, the constitution—these were the watchwords of his policy. His foreign policy was the continuation and development of that of Chatham, Pitt, Canning, and Palmerston, essentially aggressive and imperialist. His domestic policy was far ahead of his party's, yet he managed, unlike Peel and Gladstone, who disrupted the party to lead it to concessions of which it had not thought—to “educate it,” as he himself said. He found the Conservatives a party of obstruction, reactionary, and out of touch with the times; he left them in line with modern development and in a position to inaugurate reforms. A Tory in theory, he was liberal in practice. What else could be said of a man who at the outset of his career advocated the establishment of the Roman church in Ireland, the enfranchisement of the British

peasantry, the reform of the provincial administration?

Disraeli's triumphs in the House of Commons were largely due to his great skill as an orator and a debater. His skill lay in a clear and dignified presentation of facts and, above all, in his marvelous use of wit and satire. This remark holds also for his literary works, the chief flavor of which lies in the witty introduction of contemporary celebrities. They often contain beautiful descriptions, but excel in the portrayal of what we call society. He writes best in the language of the salons and club-rooms. Among his best works are: *Henrietta Temple* (1837); *Coningsby* (1844), a vindication of the Jewish race; *Sybil* (1845); *Tancred* (1847), . . . in Oriental descriptions; *Lothair* (1870), a story of a weak-minded nobleman, with incidental descriptions of the life of very exalted personages in British society (1880). *Endymion* is well known and characteristic, but far inferior to *Coningsby* and *Sybil*.

Personally he was affable, constant in friendship, and prompt to discover and aid merit. In his youth he was eccentric in dress and manners, but this he outgrew; he was always theatrical and fond of attracting attention. His private life was above reproach. He married Mrs. Wyndham Lewis, a rich widow much older than himself, in 1839. He found in her "the perfect wife," and when she died in 1868 he felt "that he had no longer a home."

Thompson, *Public Opinion and Lord Beaconsfield* (ib., 1886); T. Martin, *Memorials of Lord Beaconsfield* (ib., 1881). Consult also the Lives by J. S. Mills (ib., 1863); T. P. O'Connor (ib., 1878), hostile; G. Brandes (Copenhagen, 1878; Eng. trans., New York, 1880), favorable; C. Clarigny (Paris, 1880); A. C. Ewald (London, 1883); F. Hitchman (ib., 1872); T. E. Kebbel (ib., 1888), excellent; Kebbel's article, "Disraeli," in *Dictionary of National Biography* (1888); J. A. Froude (ib., 1890), in S :

Prime Ministers of Queen Victoria; T. Martin, *The Life of H. R. H. the Prince Consort* (ib., 1880); Meynill, *Benjamin Disraeli* (ib., 1903); Sichel, *Disraeli* (ib., 1904); Monypenny, *Life of Disraeli, Earl of Beaconsfield* (ib., 1910-12). This last biography is in a sense both official and disinterested, for the author was intrusted with the Disraeli papers hitherto unpublished. The first two volumes only are completed.

D'ISRAELI, ISAAC (1766-1848). An English author. He was a descendant of a Hebrew family which had been in Spain and Italy. His father, Benjamin D'Israeli, went to England in 1748 and, entering into business in London, amassed a fortune. Isaac, who was born at Enfield, was educated at a school in his native town and in Amsterdam. He began his career as a poet and novelist. His *Mejnoun and Leila* (1797), of no great merit as a novel, still has the distinction of being, if not the first, at least one of the earliest Oriental romances in English. After the publication of the first volume of his *Curiosities of Literature* (1791), he discovered that his forte lay not in creative literature, but in the illustration of historical and literary character, and he devoted himself to that. His works, though

inaccurate, are interesting. By his contemporaries he was liked, both as an author and as a man. Byron wrote of him as "that most entertaining and researching writer." D'Israeli's principal works are: *Curiosities of Literature* (1791-1834); *A Dissertation on Anecdotes* (1793); *Essay on the Manners and Genius of the Literary Character* (1795); *Calamities of Authors* (2 vols., 1812-13); *Quarrels of Authors* (3 vols., 1813-14); *Inquiry into the Literary and Political Character of King James I* (1816); *Commentaries on the Life and Reign of Charles I* (1828-30); *Amenities of Literature* (1840). He was the father of Benjamin Disraeli. His *Works*, edited by his son, were published in 7 vols. (London, 1858-59). A memoir in the 1849 edition of *Curiosities of Literature*, written by his son, gives an intimate and attractive picture of him.

DISSECTION WOUNDS (from Lat. *dissecare*, to cut up, from *dis*, apart + *secare*, to cut). Injuries received during the dissection of cadavers, occurring in surgeons, those who make post-mortem examinations, in butchers and cooks. Such injuries differ from ordinary infected wounds only in being more virulent. Post-mortem examinations are peculiarly dangerous when the subject has recently died of some septic disease. Dissection wounds inflicted while working on a cadaver injected with chloride of zinc are not serious, especially if they are promptly sucked until the blood runs freely, swabbed with pure carbolic acid and alcohol, or with tincture of iodine and dressed antiseptically. If infection supervenes in spite of this, the symptoms of inflammation, swelling of the lymphatic glands, with the formation of pus, accompanied by the general symptoms—chill, fever, vomiting, and prostration—follow. See PYÆMIA; SEPTICÆMIA.

DISSEISIN, dī-sē'zīn (OF. *disseisin*, from *disseisir*, *dissaisir*, Fr. *dessaisir*, to disseise, from *des*, *dis*-, apart + *seisir*, *saisir*. It. *sagire*, to seize, from ML. *sacire*, to take possession of, from OHG. *sazzan*, Ger. *setzen*, to set). At common law, the process of acquiring title to land by a wrongful possession thereof, accompanied by a claim to the freehold. It involved the double notion of the ouster of the rightful owner from his seisin and the definite acquisition of seisin by the newcomer. Its extraordinary efficacy in making a wrongful act of dispossession the basis of a valid (though defeasible) title is due to the transcendent importance which at the feudal law attached to the bare fact of possession of lands. The person seised of lands—i.e., possessed of them and claiming them as his own—was not only "presumed" to be the rightful owner, as we should express it to-day, but was, to all intents and purposes, in his public as well as his private relations, regarded as the owner. As to the person whom he has ousted (the *disseisee*), the possessor may have been only a *disseisor*; but in the eye of the law he was invested with the title, which would pass by descent to his heir or which he could alienate at his pleasure.

Of course, this title was a defeasible one, which could by entry or by appropriate legal proceedings, taken within a limited time, be destroyed, notwithstanding its descent or alienation; but pending such action it was the only existing right in the land which was recognized by the law as an estate or legal interest. The disseisee, whom we call the rightful owner

was in effect only a rightful *claimant*, and what he had was not an estate or interest in the land, but a mere right of entry, which might or might not some time ripen into a legal estate, and certain cumbersome and expensive rights of action, which might or might not avail him. Though these rights were capable of transmission by descent, they could not be alienated or made available to another, and, if not exercised within the longer or shorter term to which they were limited by law, they were barred altogether. In the earliest period of English law only a few days were allowed for making a reentry upon lands—only so long as might be necessary to enable the disseisee to learn of the disseisin and make the necessary journey to the spot. Later the period of limitation was fixed by statute at 60 years and upward, and it is now, according to the jurisdiction, fixed at periods of 10 to 30 (usually 20) years, but the practice and effect of a disseisin, and the respective rights of the parties in the land, continue to be substantially the same as at common law. See ADVERSE POSSESSION; DESCENT CAST; LIMITATION; PRESCRIPTION; SEISIN. Consult the authorities referred to under REAL PROPERTY.

DISSEMINATION (Lat. *disseminatio*, from *disseminare*, to scatter seed, from *dis-*, away + *seminare*, to sow, from *semen*, seed). The scattering of seeds. Often used in the sense of dispersal (q.v.).

DISSEN, *dis'sen*, GEORG LUDOLPH (1784–1837). A German classical scholar, born near Göttingen. Not long after receiving his degree at the University of his native city, where he had been a pupil of the philologist Heyne, he was made professor extraordinarius (1813), and in 1817 professor in the same institution. In early life he gave especial attention to the philosophy of the ancients, but afterward devoted himself almost exclusively to æsthetic interpretation of the classics. In these he attached special importance to the development of rigid stylistic laws, which, he maintained, governed all oratorical and political compositions among the ancients. In addition to two admirable treatises, *De Temporibus et Modis Verbi Græci* (1809) and *De Philosophia in Xenophontis de Socrate Commentariis Tradita* (1812), he published editions of *Pindar* (1830), *Tibullus* (1835), and the *De Corona* of Demosthenes (1837). His minor writings, *Kleine lateinische und deutsche Schriften*, with biographical reminiscences by F. Thiersch, F. G. Welcker, and K. O. Müller, appeared after his death (1839). Consult Sandys, *A History of Classical Scholarship*, vol. iii (Cambridge, 1908).

DISSENTERS (from Lat. *dis dissentire*, to disagree, from *dis-*, apart + *sentire*, to think). A name popularly applied to those who refuse to accept the authority or conform to the laws of an established church, specifically in England, although the word “dissidents” occurs in the acts of the Warsaw Confederation of 1573, to denote the Polish Protestants of that day. As an English term it became common in the seventeenth century to denote the bodies who separated from the Church of England; though it is not commonly applied to Roman Catholics (for whom the older title was recusants), nor to members of the Episcopal church in Scotland, though both these bodies dissent from the established churches. For the history of repressive legislation in England, and its gradual miti-

gation, see TOLERATION; NONCONFORMISTS; also ESTABLISHMENTS. ECCLESIASTICAL.

DISSEPIMENT. A partition in plants such as divides an ovary into compartments.

DISSOCIATION (Lat. *dissociatio*, from *dis-sociare*, to disrupt, from *dis-*, away + *sociare*, to associate, from *socius*, associate). A term applied in chemistry to all obviously reversible decompositions. (See DECOMPOSITION.) Two kinds of dissociation are now generally distinguished: *chemical* (in which the products of dissociation are themselves free chemical substances) and *electrolytic* (in which an ordinary chemical molecule breaks up into electrically charged particles, or *ions*).

Chemical Dissociation. Like ordinary chemical decomposition, chemical dissociation involves the breaking up of a given chemical substance into parts each of which is capable of independent existence. In the case of sal ammoniac (see DECOMPOSITION) the products of dissociation are ammonia gas and hydrochloric acid—two well-known chemical compounds. Other typical examples of chemical dissociation are presented by the vapor of phosphorus pentachloride, by the tetroxide of nitrogen, and by ordinary chalk. In the case of phosphorus pentachloride, which is itself colorless, the dissociation is rendered evident by the fact that of the two products—viz., phosphorus trichloride and free chlorine—the latter is green; this dissociation may therefore be readily demonstrated by heating some phosphorus pentachloride in a glass vessel. Even more striking is the dissociation of the tetroxide of nitrogen, N_2O_4 , which is, at low temperatures and in a pure state, a yellowish, almost colorless liquid, but whose vapor breaks up, on the application of heat, into a dark, brownish-red oxide of nitrogen, represented by the formula NO_2 . Both in the case of phosphorus pentachloride and in the case of nitrogen tetroxide, lowering the temperature causes a recombination of the products of dissociation and a consequent disappearance of the color. The manner in which the dissociation of sal ammoniac may be demonstrated is described in the article on AVOGADRO'S RULE (q.v.). It must be observed here that, according to H. B. Baker (1893), sal ammoniac does not dissociate at all if very carefully dried, nor do perfectly dry ammonia and hydrochloric acid combine to form sal ammoniac. The extent to which a compound may be dissociated is strongly influenced by two physical factors—viz., temperature and pressure. Thus, in the case of nitrogen tetroxide, the application of a moderate degree of heat would cause only a fraction of the total amount employed to break up. But, as the temperature would be allowed to rise, the dissociated fraction would increase, and this would be plainly shown by the color of the gas rapidly becoming more and more intense. On the contrary, increasing pressure would cause the dissociated fraction to diminish, as would be indicated by the gradual disappearance of the color. Careful experiments, carried out at the temperature of about 50° C., have shown that at that temperature nitrogen tetroxide is all but completely dissociated if the pressure is very greatly reduced; under a pressure of about 498 millimeters of mercury, only a half of the tetroxide is broken up. In the case of a single solid substance whose dissociation products include one or more gases, matters are somewhat different. An elevation of temperature causes,

just as in the case of gases, an increase of the dissociated fraction; but at any given temperature the pressure of the gaseous product of dissociation *cannot* be increased. The phenomenon is in this respect analogous to the evaporation of water. It is well known that for every given temperature the vapor pressure of water is constant; an attempt to increase that pressure would be unsuccessful and would only cause some of the vapor to condense. This is precisely what happens in the classical case of the dissociation of chalk within a closed vessel. Under the influence of heat, chalk breaks up into quicklime and carbonic acid. The higher the temperature, the less chalk remains undissociated and the greater the amount of the carbonic acid produced. But if at a given temperature we should attempt to increase the pressure by diminishing the volume within which the substances are confined, the result would be that some of the carbonic acid would recombine with the quicklime, and thus the original pressure would soon be reestablished. This fixed pressure is often referred to as the "dissociation tension" of chalk, just as the pressure of water vapor at some given temperature is spoken of as the vapor tension of water at that temperature. Again, just as the vapor tension of water is the same whether the amount of water is large or small, so is the dissociation tension of a solid substance independent of the amount of the latter experimented upon. See PHASE RULE.

Electrolytic Dissociation. Quite different from the phenomenon of chemical dissociation is electrolytic dissociation; and it must be borne in mind that, while the former is a fact, the latter is theoretically inferred to be the cause of the exceptional behavior of many solutions, but cannot be gotten at directly. Nevertheless the theory of electrolytic dissociation is now almost generally accepted by chemists, and careful investigation brings forward, month after month, new proofs of the extreme probability of its correctness and usefulness. According to this theory acids, bases, and salts break up, when dissolved in water, into atoms or atomic groups, half of which are charged with positive, half with negative electricity. Thus, hydrochloric acid is supposed to dissociate according to the following equation:

caustic potash dissociates as follows:

the salt called potassium chloride, as follows:

These equations must not, however, be taken to mean that, e.g., a solution of potassium chloride contains chlorine gas and the metal potassium in the free state. Indeed, comparing a solution of potassium chloride with one of chlorine gas, it may be seen that, while some free chlorine is constantly escaping from the latter, no free chlorine can be detected in the former; a solution of potassium chloride exhibits neither the color, nor the odor, nor the bleaching power of free chlorine. The symbol $\overline{\text{Cl}}$ denotes what is called an electronegative chlorine "ion," and the existence of an ion is not an independent existence, but involves necessarily the existence of another ion, carrying an equal charge of the

opposite form of electricity. Free chlorine gas would, however, *form* from the chlorine ions if the latter lost their electric charges; which is precisely what happens when the solution is subjected to a process of electrolysis. When the electrodes of a galvanic battery are immersed in the solution, the negative chlorine ions are attracted towards the positive electrode, by which their electric charge is neutralized. The chlorine ions then become simply chlorine atoms, and these combine in pairs, forming molecules of free chlorine gas. At the same time the positive ions are attracted and transformed into a free chemical substance, at the negative electrode; for neither can electropositive nor electronegative ions exist alone. A current of electricity is then said to pass through the solution, and the latter is said to be electrolyzed. Now, if this explanation of the mechanism of electrolysis be correct, it is evident that the electrical conductivity of a solution must be proportional to the number of free ions in it; and hence the numbers of free ions in different solutions may be ascertained by measuring the conductivities of the solutions. It is equally evident that, if the explanation is correct, the total number of *particles* (ions as well as molecules) in a solution, say, of potassium chloride is greater than what it would be if that salt were not dissociated. Comparing a solution of an electrolyte (i.e., an acid, base, or salt) with a solution of an equivalent quantity of any nonelectrolyte, the former solution must contain a larger total number of particles than the latter; because in the latter the number of particles is not increased by dissociation.

These considerations have been applied to explain the abnormal behavior of solutions of acids, bases, and salts. When dissolved in water, these substances have been known to affect its physical properties much more than equivalent amounts of substances of any other class. Thus, dissolving a given amount of common salt causes the boiling temperature of water to become much higher than dissolving an equivalent amount of sugar (a nonelectrolyte); and the same may be said of the lowering of the freezing point of water and of certain other changes in its physical properties. In the case of a nonelectrolyte, the elevation of the boiling point, as well as the depression of the freezing point, is found, for moderate amounts of substance dissolved, to be proportional to those amounts and can therefore be readily calculated. In the case of electrolytes, and only of these, that proportionality is not found to exist; and before the invention by Arrhenius of the theory of electrolytic dissociation, the exact change in physical properties of the solvent produced by these substances could not be calculated. The theory of dissociation attacks this problem in the following manner: It starts with the principle that the *relative numbers* are proportional to the number of *particles* of the dissolved substance; combines this principle with the idea that the number of free ions in a solution is shown by the electrical conductivity; calculates the total relative number of particles from the relative number of free ions present; and then calculates the elevation of the boiling point and the depression of the freezing point from the total number of particles. The figures thus obtained by theoretical calculation are found to be in remarkably close agreement with the results of actual observation, and this in-

dicates the great probability of the correctness of the theory of dissociation.

Electrolytic dissociation is usually incomplete. That is to say, of the total number of molecules in solution, only some are usually dissociated into ions, the rest remaining undissociated. The dissociated fraction, representing the "degree of dissociation," depends on two factors: the concentration of the solution and the temperature. When the concentration is diminished by adding pure water to the solution, the degree of dissociation becomes greater; by adding a very large amount of water to the solution, the dissociation may in many cases be rendered complete, i.e., no molecules may be left undissociated. As to the influence of temperature, it is known that a rise of temperature causes in some cases an increase, in other cases a decrease, of the degree of dissociation. Herein is an interesting difference between electrolytic and chemical dissociation, as the latter is invariably furthered by rise of temperature.

The weakest point in the electrolytic dissociation theory is where it touches the fundamental principle of chemical dynamics, the law of mass action. (See REACTION, CHEMICAL.) According to the latter, the *square* of the concentration of the ions of a "binary" electrolyte (i.e., one whose molecule splits up into two ions, like KCl) must at all dilutions remain proportional to the concentration of the undissociated molecules. Experiment, however, shows that all "strong electrolytes" (i.e., such as are greatly dissociated) fail to obey this law! True, the deviation from the law is quite similar in all cases: the *cube* of the ion concentration is found to be (roughly) proportional to the *square* of the undissociated fraction. But this does not help matters much, and the failure of the dissociation theory to agree with a well-founded principle of chemical dynamics, in the case of all salts and all strong acids and bases, is still awaiting an adequate explanation.

Nevertheless the theory of electrolytic dissociation performs in a remarkable degree the function of a truly scientific theory, viz., that of bringing out a connection between phenomena that are seemingly very different in their nature. Who would imagine, e.g., that the boiling or freezing temperature of a solution of common salt has any connection with its electrical conductivity? Arrhenius' theory establishes an exact mathematical relation. The theory draws for us a picture of things that lie as far beyond the power of our senses as the remotest of the unseen worlds in space; yet the more proofs are adduced of the correctness of the theory, the more probable it becomes that the picture drawn by it is actually true to reality. To the practical scientist, however, this is of secondary importance. Much more important is the fact that the ionic theory furnishes indisputably valuable *working principles*. It can be and has been criticized; and scientific criticism is always useful. Nevertheless many able chemists are devoting their energy to develop it and apply it to all possible cases. Let the theory be abandoned as inadequate to-morrow; to-day it leads us to the discovery of new relations, and it has correlated (i.e., explained) a variety of facts that were unintelligible yesterday. It has already explained many of the facts of organic and analytical chemistry; it has explained the behavior of the different indicators used in alkalimetry and acidimetry;

and it is being more and more extensively applied to problems of physiology and bacteriology. Thus, the researches of Louis Kahlenberg have shown that the poisonous action of acids, bases, and salts depends on the degree of their dissociation in solutions. Similar results were obtained by Paul and Krönig, who investigated the action of acids and bases, and of the salts of mercury, gold, and silver, on the spores of the anthrax bacillus and on the vegetative forms of *Staphylococcus pyogenes aureus*. Grützner and Haffner have shown that the precipitation of casein from milk by the addition of acids depends on the degree of dissociation of the latter, and that the presence of salts modifies this relation in accordance with the theory of dissociation. The researches of Jacques Loeb have shown the importance of the applications of the electrolytic theory to the physiology of man and of the lower animals. Consult: Talbot and Blanchard, *Electrolytic Dissociation Theory* (2d ed., New York, 1907); H. C. Jones, *Freezing-Point, Boiling-Point, and Conductivity Methods* (2d ed., Easton, 1912); id., *Electrical Conductivity, Dissociation and Temperature Coefficients of Conductivity* (Washington, 1912); also the treatises on physical chemistry and electrochemistry mentioned under CHEMISTRY and ELECTROCHEMISTRY. See also SOLUTION; ACIDS.

DISSOLVING VIEWS. Pictures on a screen produced by a mechanical device attached to the projection lantern or stereopticon which causes the image furnished by one slide to dissolve, as it were, or blend into that of the following slide. Two lanterns are generally employed to secure this effect, which is obtained by gradually covering one of the projection lenses and allowing the rays from the other to fall on the screen.

DIS/SONANCE (Lat. *dissonantia*, from *dissonare*, to sound harshly). The simultaneous sounding of two or more tones foreign to a major or minor triad. Dissonance produces a feeling of unrest requiring a resolution into consonance (q.v.). This feeling of unrest is attributed to the complex ratios existing between the number of vibrations of dissonant intervals; whereas the ratios of consonant intervals are always simple. In reality it is impossible to set up any exact limits of dissonance, as what may seem dissonant to one person may seem consonant to another. But it is easy to establish certain landmarks within which each individual will, to a certain extent, determine the bounds of dissonance. Dissonant intervals are the major and minor second and all augmented or diminished intervals. (See INTERVAL.) Chords containing one or more dissonant intervals are dissonant chords and require resolution. The dissonant chords are all augmented and diminished triads, as well as all chords of the seventh and ninth. See ACOUSTICS; HARMONY; TRIAD.

DISTAFF (AS. *distaf*, from * *dise*, OE. *diseen*, to dress with flax for spinning, to bedizen, LG. *diesse*, flax on the distaff + *staf*, staff). The staff on which the flax or wool is fastened, and from which the thread is drawn in spinning. As represented in ancient art, and still used by Greek peasants, it is a straight rod, from either side of which projects near one end a semicircle of cane or withes, forming a bed to which the wool or flax is attached. In both ancient and modern art the Fates are usually represented

with it, engaged in spinning the thread of life. (See PARCÆ.) It has ever been considered as the peculiar emblem of feminine as opposed to masculine occupations, and is sometimes used figuratively for a woman. See SPINNING.

DISTAFF'S DAY, SAINT. A name given to January 7, because it marks the return of the women to their usual daily occupation after the Christmas festivities terminating on the Twelfth Day, January 6.

DISTANCE (OF., Fr. *distance*, from Lat. *distantiā*, from *distare*, to be distant, from *dis-*, apart + *stare*, Gk. *istánai*, *histanai*, OChurch Slav. *stati*, Skt. *sthā*, to stand; connected with OHG. *stēn*, Ger. *stehen*, to stand, and ultimately with Goth. AS. *standan*, Eng. *stand*). In navigation (q.v.), the distance between any two places is the length of the rhumb line (q.v.) between the places. On the ordinary sailing chart (Mercator's projection) the rhumb line is straight. Also, the angular distance between heavenly bodies measured on the arc of the great circle passing through them.

The limit of view in a picture, or *point of distance*, as it is called in perspective, is that portion of the picture where the visual rays meet: the *middle distance* being the central portion between the extreme distance and the foreground. Distance, in a picture, is obtained by painting the tones that express the relative remoteness of a distant object with the same directness and truth that is employed in portraying those objects that are near at hand, or in the *foreground*, as it is called. When distant objects are thus true in color, the quality of distance will be produced by the diminution in size which obedience to the laws of perspective exacts. See PERSPECTIVE.

DISTANCE, or DEPTH, PERCEPTION OF. When we look at objects, we think that we see how far away they are. Yet their distance is not directly given with the act of vision. It is true that a few writers, e.g., Hering and James, believe that the primitive field of view is not altogether superficial, and that distance is "a genuinely optical feeling"; but the majority agree that it is derivative, built up by the association of tactual ideas with certain "signs," visual and strain sensations arising in the use of the eyes. In either case it is admitted that the "optical signs" themselves—the "criteria of distance," as they are called—are essential to the complete development of the idea. We must distinguish between the "primary," immediately given, and the "secondary," or indirect criteria. The former are (1) dissimilarity of objects; (2) the number of objects; (3) the partial covering of objects by the nearer; (4) movement of objects in the visual field, e.g., swiftly moving objects seen from the window of a moving train are known to be near; (5) movement of our own head or body, with consequent relative displacement of objects differently distant; (6) distribution of light and shade, e.g., the illusion of depth given by appropriately shaded stage settings; and (7) visual angle, i.e., the apparent size of known objects. The two last are the most influential.

While, however, the full and complete perception of depth implies the aid of vision, there can be no doubt that the blind have the perception in some degree. The sensations of pressure are bidimensional; and the movement of one part of the body over another, of the hand over external objects, of the whole body in locomotion, appears to supply the data necessary for at least a crude perception of depth. The blind have no direct means of refining this perception into an exact apprehension of distance; for that they must have recourse in the special case to such secondary criteria as the counting of steps. In all cases, the refinement is rare, and the idea of the third dimension in general remains, for the majority of blind persons, both vague and intermittent. Consult: Berkeley, *An Essay Toward a New Theory of Vision* (London, 1709); Wundt, *Human and Animal Psychology*, trans. by Creighton and Titchener (ib., 1901); Titchener, *Text-Book of Psychology* (New York, 1910); James, *Principles of Psychology* (ib., 1890).

DISTEMPER (OF. *destemprer*, to distemper, ML. *distemperare*, from Lat. *dis-*, apart + *temperare*, to temper, from *tempus*, time). An acute infectious disease of young carnivorous animals, especially young dogs, caused either by an ultramicroscopic virus or by an organism recently described as *Bacillus bronchisepticus*. The disease is characterized by febrile manifestations, and an acute catarrh of the mucous membranes, which is frequently followed by catarrhal pneumonia and in some cases by the development of nervous symptoms. The *peracute form* of the disease is manifested in a sudden loss of appetite, depression, groaning, *stiffness*, as well as high fever. After two or three days the temperature rapidly drops below

indications of the distance of objects, at least up to a few hundred feet. Convergence, together with accommodation, is, according to Wundt and Airer, the essential basis of the perception of depth. But other authorities, notably Wheatstone, Hering, and Hillebrand, lay stress upon the dissimilarity of retinal images. We have given us, in our two eyes, two pictures of every object seen. The difference between the two pictures increases with the nearness of the object. The testing of the part played by this disparity in the perception of distance led to the invention of the stereoscope, which enables us artificially to reconstruct the actual retinal conditions of binocular vision.

In our daily life it is perhaps true that the secondary criteria become most important; they are at least most in evidence. These indirect data of distance are seven in number: (1) linear perspective, i.e., the perspective of drawing, the course of the contour lines of objects in the visual field; (2) aerial perspective, i.e., distinctness of outline and color tone; (3) the number of objects, or the partial covering of objects by the nearer; (4) movement of objects in the visual field, e.g., swiftly moving objects seen from the window of a moving train are known to be near; (5) movement of our own head or body, with consequent relative displacement of objects differently distant; (6) distribution of light and shade, e.g., the illusion of depth given by appropriately shaded stage settings; and (7) visual angle, i.e., the apparent size of known objects. The two last are the most influential.

While, however, the full and complete perception of depth implies the aid of vision, there can be no doubt that the blind have the perception in some degree. The sensations of pressure are bidimensional; and the movement of one part of the body over another, of the hand over external objects, of the whole body in locomotion, appears to supply the data necessary for at least a crude perception of depth. The blind have no direct means of refining this perception into an exact apprehension of distance; for that they must have recourse in the special case to such secondary criteria as the counting of steps. In all cases, the refinement is rare, and the idea of the third dimension in general remains, for the majority of blind persons, both vague and intermittent. Consult: Berkeley, *An Essay Toward a New Theory of Vision* (London, 1709); Wundt, *Human and Animal Psychology*, trans. by Creighton and Titchener (ib., 1901); Titchener, *Text-Book of Psychology* (New York, 1910); James, *Principles of Psychology* (ib., 1890).

DISTEMPER (OF. *destemprer*, to distemper, ML. *distemperare*, from Lat. *dis-*, apart + *temperare*, to temper, from *tempus*, time). An acute infectious disease of young carnivorous animals, especially young dogs, caused either by an ultramicroscopic virus or by an organism recently described as *Bacillus bronchisepticus*. The disease is characterized by febrile manifestations, and an acute catarrh of the mucous membranes, which is frequently followed by catarrhal pneumonia and in some cases by the development of nervous symptoms. The *peracute form* of the disease is manifested in a sudden loss of appetite, depression, groaning, *stiffness*, as well as high fever. After two or three days the temperature rapidly drops below

normal, whereupon death soon appears under comatous symptoms. The *acute form* also is inaugurated by high fever, the temperature rising rapidly to 40° C. or over, and remaining at this height for one or two weeks, or it falls slightly in one or two days, and then there exists only moderate fever. In severe cases the temperature rises again, owing to the development of pneumonia. The thickened slimy mucus which the inflamed membrane after some days secretes accumulates about the eyes, nostrils, and respiratory passages and, lodging in the bronchial tubes, prevents the free access of air and the proper purification of the blood. Hence ensue distressed breathing, increasing weakness, and symptoms of nervous disturbance, such as staggering gait, chorea (q.v.), and fits. It is a remarkably frequent disease of young carnivora, especially of young dogs—so much so that the great majority of the latter become affected before reaching the age of one year, the delicate, highly bred, and artificially treated varieties suffering most severely. Natural infection occurs through direct or indirect contact with affected animals. The virus is present in the catarrhal secretions of the mucous membranes and is evidently in most instances taken into the digestive canal with the food and water. Susceptibility diminishes with advancing age, so that animals over three years old are but rarely affected. Although young cats are also susceptible to the disease, it occurs in these animals much less frequently than in dogs. The symptoms and anatomical changes correspond with those of dogs affected with distemper, but the nervous symptoms are less common, and the exanthema which appears in almost one-half of all cases in dogs is usually absent.

In treating the disease the affected animals should be placed in a clean, uniformly warm place, protected from draughts, and furnished with concentrated nourishment, such as milk and strong meat broth with the yolk of an egg beaten into it. Several daily feedings with chopped salted meat cooked in steam is very beneficial. In the presence of gastrointestinal catarrh gruel may be given to it. All irritating remedies must be carefully avoided. As an abortive treatment, subcutaneous injections of trichloride of iodine are indicated. For depression and weakness, nervous stimulants are recommended, such as alcohol, in proper dilutions and in small but frequently repeated doses. When the fever becomes severe, antipyretics, such as phenacetin, should be administered. The catarrh of the respiratory organs is treated to the best advantage by the inhalations of warm vapors containing expectorants. The gastrointestinal catarrh should be treated first by regulating the diet, as described, and in the first days of the infection a cathartic, such as castor oil or calomel, as well as salol, should be given. If vomiting is present, this may be controlled by the administration of cracked ice, water containing soda, salicylate of bismuth, and in emergency with opium. Constipation, if present, should be corrected by half an ounce each of castor oil and olive oil, to which in large dogs a few grains of gray powder is a useful addition. In the presence of nervous symptoms anodynes and antispasmodics are recommended. The various serums for distemper are not very promising, as they are prepared with the aid of bacteria, which at best

are of importance only in the secondary organic lesions. Give frequently and in small quantities at a time milk and bread, or any other such simple and digestible food; and when recovery is tardy and weakness ensues, endeavor by nursing and by use of tonics and stimulants to support the strength. The same principles should be applied in treating the disease in cats.

The term "distemper" is sometimes applied to influenza (q.v.) in horses and epizootic pleuropneumonia (q.v.) in cattle. For an account of distemper in pigs, see HOG CHOLERA.

Consult Hutyra and Marek, *Pathology and Therapeutics of the Diseases of Domestic Animals*, vol. i (Chicago and London, 1912), and E. W. Hoare, *A System of Veterinary Medicine*, vol. i (ib., 1913).

DISTEMPER (IN PAINTING). See TEMPERA. **DISTHENE.** See CYANITE.

DISTICH, *dis'tik* (Lat. *distichon*, Gk. *διστίχον*, *distichon*, distich, from *δι*, *di*, double + *στίχος*, *stichos*, row, line, from *στέλλειν*, *steichein*, to tread). The classical name given to any couplet making complete sense, but especially to a hexameter and a pentameter. It was much used by the Greeks and Romans as a vehicle for the expression of single thoughts and sentiments, and hence became almost exclusively employed for the classical epigram. It was employed largely also in elegiac verse. (See ELEGY.) The great poets of modern Germany—Goethe, Schiller, etc.—have also shown a fondness for the distich and a remarkable skill in the use of it. See also CATO, DIONYSIUS.

DISTILLA'TION (Lat. *destillatio*, from *destillare*, to distil, from *de*, down + *stillare*, to drop, from *stilla*, drop). A process consisting in the evaporation of liquids by boiling and the subsequent liquefaction of their vapors by cooling. The purpose of distillation is to separate different substances from one another more or less completely. The process has been in use

FIG. 1. DISTILLING APPARATUS AS DRAWN IN THE THIRD CENTURY A.D.

FIG. 2. DISTILLING APPARATUS AS DRAWN IN THE FIFTH CENTURY A.D.

since ancient times, and in the first centuries of our era was employed in much the same manner as at the present time. In the third century A.D. sea water was by distillation rendered fit for drinking; and it was known that practically pure water may be isolated from wine

and other aqueous mixtures by distillation. The alchemists obtained the mineral acids and other valuable substances by processes of distillation, and at the present day distillation is one of the most potent processes in the hands of the scientific and the industrial chemist.

FIG. 3. MODERN DISTILLING APPARATUS.

What usually takes place during the distillation of a mixture is, in a sense, very simple: The given liquid becomes divided into portions of unequal volatility, every fraction that distills over being more volatile than the fraction that still remains behind. And as less volatile liquids boil at higher temperatures than more volatile ones, it is obvious that the boiling point of a mixture distilling under *constant pressure* must continually rise. If the mixture were allowed to evaporate at *constant temperature*, its vapor tension must continually decrease. A liquid whose vapor tension during evaporation might increase is an impossibility, for almost obvious reasons. Such a liquid and its vapor would constitute a system whose volume would increase, and not diminish, if some compressing power was brought to act upon it; which is absurd. By means of such a liquid it would be easy to obtain a form of what physicists call "perpetual motion of the second kind," which the science of thermodynamics recognizes as no less impossible than the creation of mechanical work out of nothing. (See THERMODYNAMICS.) But while the vapor tension of an evaporating mixture cannot possibly increase, it may, and in certain cases does, remain constant. Thus a mixture of 96 parts (by weight) of absolute alcohol and 4 parts of water will evaporate without change of vapor tension (the exact composition of this mixture was established by W. A. Noyes and Warfel in 1902). The question therefore remains, What mixtures are subject to decrease of vapor tension, and what mixtures evaporate without such change? The answer is: If the ingredients are present in such proportions that the vapor tension of the mixture is either the highest or the lowest that can be obtained with the given substances, then the vapor tension will remain constant during evaporation; in every other case it will decrease. If for a certain proportion of the ingredients the vapor tension of the mixture is lower than for any other proportion, the composition of the boiling liquid will approach nearer and nearer to that proportion as a limit; once that limit reached, the vapor tension cannot decrease any further, and thenceforward the composition of the distilling liquid must remain unchanged: the

vapor passing off and the liquid remaining behind will have precisely the same relative composition. Again, if at a certain temperature a given mixture has the highest vapor tension that can possibly be obtained with its ingredients, then a separation into more and less volatile portions is evidently impossible, and hence the distillation can produce no change of composition. A mixture of 96 parts of absolute alcohol and 4 parts of water has at its boiling temperature a higher vapor tension than any other mixture of water and alcohol at the same temperature; and this is why that mixture distills over without change of composition.

From the above it may be seen that the possible changes of the total vapor tension of a mixture determine in a general manner the direction in which the changes of composition will proceed in course of a distillation. To recapitulate, distillation can effect a change in the composition of a given mixture only if *both* of the following conditions are fulfilled: (1) if there exist mixtures of the same substances whose vapor tensions are *less* than that of the given mixture; (2) if there also exist mixtures of the same substances whose vapor tensions are *greater* than that of the given mixture. Distillation will then divide the given mixture into, say, two portions, one of which will be more, the other less, volatile than the given mixture. But the exact course of a distillation is far from being determined by these laws, which were, in substance, established by Kononoff in 1881. For example, no answer is thus furnished to the question: Being given a mixture of a pound of water and a pound of alcohol, and supposing that half the mixture has distilled over, what is the composition of the distillate?

In considering *quantitative* questions like this, it must be borne in mind, again, that separation of substances by distillation is only possible when the mixed vapor has a different composition from the mixed liquid by which it is emitted. From this it follows that the quantitative laws of fractional distillation must be based on a principle by which the composition of a mixed liquid and that of its vapor are correlated quantitatively. And, further, such a relationship between the composition of liquid mixtures and of their vapors can only be discovered and tested if we know how to determine the composition of mixed vapors experimentally. This last problem is not an easy one, and in many cases the older observations of different investigators disagree so grossly that the true composition of the vapors could not be considered as even approximately known. In recent years, however, Rosanoff, with several collaborators, has worked out two experimental methods which permit of ascertaining the composition of the vapors from liquid mixtures with certainty and without much difficulty. Rosanoff has, further, deduced a relationship between the vapor tensions of liquid mixtures and the composition of their vapors, and has shown how with the aid of this relationship it is possible to foretell the course of a distillation with quantitative precision. Given, then, the total vapor tensions of various mixtures of two liquids *A* and *B* (and these total vapor tensions are easily measured), it is to-day easy to answer a question like the one proposed above: viz., if from a certain weight of a given mixture of *A* and *B* a part should be removed by distillation, what would be the composition of the part removed

and what the composition of the part remaining behind? The subject is too mathematical to permit of an adequate explanation here. The student may be referred to Lord Rayleigh's paper in the *Philosophical Magazine* for 1902 and to the papers by Rosanoff and his coworkers in the *Journal of the American Chemical Society* since 1909 and the *Journal of the Franklin Institute* for 1911.

An older theory of distillation, developed by Sydney Young in collaboration with Thomas and Barrell, was based on an assumption first recommended by F. D. Brown, viz., that the ratio of the weights of the components in the vapor is, at every instant during a distillation, proportional to the ratio of the weights of the components in the liquid. But this assumption, and hence also the theory of distillation founded upon it, can now be positively stated to be erroneous except in certain very rare cases.

The theories of distillation just mentioned deal with distillation in which the vapors emitted by the boiling mixtures are immediately and completely removed as soon as formed, to be received in reliquified form in separate containers. In practice—in the laboratory and especially in industrial distillation—the vapors are partially recondensed before removal, in upright still heads, or columns, and thereby the desired separation of the ingredients is greatly hastened. The best still heads used on a laboratory scale are those of Le Bel and Henninger and of Sydney Young. The best-known stills employed industrially are those of Coffey and of Savalle. In all such apparatus the still heads are provided with a succession of traps, of one form or another, in which the vapor bubbles through small quantities of liquid produced by the partial condensation of preceding fractions of the vapor; this progressive washing of the rising vapor in the consecutive sections of the still head, combined with the cooling effect of the air head, produces the desired of the vapor and its consequent gradual enrichment in the more volatile component; so that the vapor finally escaping from the still head into the condenser is far richer in that component than the vapor first given off by the liquid boiling in the still.

The greatest practical importance must at the present time be attributed to an idea first introduced by Warren, in the sixties of the nineteenth century, later (1880) investigated by F. D. Brown, and in recent years reinvestigated, extended, and practically applied by Rosanoff. Warren conceived the idea of passing the vapors rising from a boiling liquid mixture through an upright still head whose temperature was kept constant; by actual experiments he showed that in this manner the distillation yielded a much more uniform product than would otherwise be obtained. Brown investigated the matter in the case of mixtures of two liquids and discovered the general principle involved, now known as Brown's law: that, independently of the composition of the mixture boiling in the still, the vapors escaping through a regulated still head have a constant composition, viz., the composition of the vapor given off by that particular liquid mixture which boils at the temperature at which the still head is maintained. Rosanoff, next, showed that this law works only within certain definite limits discovered by him, and that in the case of mixtures of more than two components the law assumes a still further modi-

fied form. On the basis of the Brown-Rosanoff law he has, finally, developed a distillation process depending on the employment, not of one single, regulated still head, but of a definite number of such still heads connected in series, the constant temperature of each still head to bear a certain definite relation to those of the other still heads of the series. Practical tests on all types of cases have demonstrated that the results yielded by such an apparatus are predeterminable and absolutely uniform, so that the Rosanoff process may be considered as the long-sought general solution of the problem of fractional distillation.

Bibliography. The best general work dealing with the older theories of distillation is Young's monograph, *Fractional Distillation* (London, 1903); consult also Kuenen, *Verdampfung und Verflüssigung von Gemischen* (Leipzig, 1906). A good description of the older forms of industrial distillation apparatus in use may be found in Stammer, *Die Branntwein-Industrie*, pp. 685-866 (Brunswick, 1895). Many valuable data on evaporation and condensation will be found in Hausbrand, *Verdampfen, Kondensieren, und Kühlen* (5th ed., Berlin, 1912). See CHEMISTRY; BOILING POINT; EVAPORATION; DISTILLED LIQUORS.

Destructive Distillation. This is quite different from the process described above. For while that process is purely physical and involves no chemical change whatever, destructive distillation, as implied by the term, causes profound chemical changes in the materials subjected to it. Examples of destructive distillation are: the heating of coal in gas works at a red heat, when it resolves itself into coke, which is left in the retort, and coal gas, naphtha, tar, etc., which distill over into suitable receivers; the treatment of cannel coal at and below a red heat, when it yields much paraffin wax and paraffin oil; and the distillation of wood in close vessels, at a red heat, when charcoal is left in the vessel, and wood vinegar, wood spirit, tar, etc., pass over in vapor, and are condensed. See TAR; COAL TAR; GAS, ILLUMINATING; PARAFFIN; ACETIC ACID; DIPPEL'S ANIMAL OIL; ETC.

DISTILLED LIQUORS, or ARDENT SPIRITS. Alcoholic liquors manufactured by the process of distillation (q.v.). They may be produced from fermented liquors or directly from the raw materials, which must contain a large percentage either of sugar or of starch. An example of the first class is brandy, which is made by distilling wine. An example of spirit produced from saccharine material is rum, which is made from molasses, while whisky, made from corn, rye, barley, or other cereal, is an example of spirit made from a starchy material. The process of distillation may be so conducted as to produce an alcoholic beverage or simply a "raw spirit." From the latter, by a process described below, is obtained the rectified spirit which is used as a basis in the manufacture of various alcoholic beverages. Rectified spirit is also employed in the arts, and from it, by a process of purification, is obtained the absolute ethyl alcohol of the chemist. See ALCOHOL.

History. All the intoxicating drinks used in ancient times seem to have been the product of fermentation only. The art of distilling liquors is first mentioned by an Arabian physician of the tenth century, Albukassen by name, though

the invention is attributed by some to the northern nations. The name *aqua vite*, given to distilled spirits, shows what an estimate was put upon the discovery by early physicians and alchemists. One of them "declares this admirable essence to be an emanation from divinity, an element newly revealed to man, but hid from antiquity because the human race were then too young to need this beverage destined to revive the energies of modern decrepitude."

Process of Manufacture. Spirits were first distilled from wine, but an endless variety of substances are now used in their manufacture. Alcohol, however, is the essential element in all spirits. It results from the decomposition of sugar, which, by the process of fermentation, is resolved into carbonic acid and alcohol. Sugar is therefore the direct source of alcohol, and for this reason sweet vegetables and fruits may be converted into spirits. But starch is readily converted into sugar by means of the substance called diastase, which is found in malt and in germinating seeds generally. (See BEER; BREWING.) Hence starch as well as sweet vegetables may be used in the manufacture of spirits. In making distilled liquors, when the raw material is a fermented liquor, it is ready to be distilled without further preparation; when it is a sugar, however, it must first be fermented and then distilled; when it is a starch, another initial process, to convert the starch into sugar, is necessary.

Mashing or Preparation of the Wort. To saccharify the starch is the object of the initial process, technically known as *mashing*. This process consists in mixing the raw grain, properly ground, with malt and with water at a temperature of about 150° F. Corn, barley, oats, and rye are the grains commonly used. In England and the United States most distillers use a mixture of raw and malted grain, in which the larger proportion is raw. The first step where raw grains are used is to cook the starch so as to render it soluble, and this is generally accomplished by steaming under pressure. This is then mixed with ground malt. This treatment requires from one to four hours, during which time the mash is kept at a uniform temperature of 145° F. by successive additions of hot water. After this saccharine infusion, technically called *wort*, has acquired its maximum density, as indicated by a saccharometer, it is drawn off. Fresh water is then poured upon the residue and allowed to stand to form a second wort. This is added to the first. A third wort, used to infuse a new mixture of grain, is sometimes made. In this method of direct mashing, nearly 10 per cent of the grain is not decomposed. The waste may be reduced to 5 per cent by heating the grain and water before the malt is added.

In Germany, where potatoes are used for the manufacture of spirits, the potatoes are steamed before the malt is applied. This is advisable because potatoes contain a much smaller proportion of starch than the cereals. By steaming, the starch cells are thoroughly broken and the starch reduced to a condition in which it is easily acted upon. Several different forms of apparatus have been devised for this purpose. In that of Henze, which is largely used, the steam is applied under pressure and the potatoes are reduced to a pulpy liquid, in which form they run into the mash tub from an opening in the bottom of the ap-

paratus. After this mass has cooled to the proper temperature, the malt is added and the wort formed as described above.

Fermentation. This is effected by adding either brewer's or compressed yeast to the wort prepared as described above, or to a saccharine liquid obtained from molasses, beets, or other sugar-producing fruits or vegetables. Eight to 10 parts of brewer's yeast are mixed with 1000 parts of grain mash, and with a larger proportion of yeast for potato mash. The chemical processes involved in fermentation, by which the sugar is resolved into carbon dioxide and alcohol, are discussed under YEAST and FERMENTATION. From three to nine days are consumed in fermentation. The process is continued until the density of the liquid ceases to lessen, as indicated by the saccharometer. Hydrofluoric acid has been quite generally used in the past in the fermentation process. Sadtler states, in his *Industrial Organic Chemistry* (New York, 1896), that the following advantages are claimed for its use: "(1) by preventing the losses due to secondary fermentation the alcoholic yield is increased; (2) this yield is especially maintained when raw materials of somewhat inferior quality are used, when, without the hydrofluoric acid, the yield would be diminished; (3) the development of foaming in the fermentation is largely prevented." The best practice to-day, however, is to prevent contamination of the mash and use pure yeast.

In making spirit from beets sulphuric acid is used during the fermentative process. Much of the beet spirit is made from molasses derived as a by-product from the manufacture of beet sugar. But in France it is customary to make inferior beets directly into spirit. Only a small quantity of yeast is required, and fermentation is completed in about 24 hours. In the West Indies the molasses produced in making cane sugar is utilized in the manufacture of rum. (See the article RUM for a description of its manufacture.) The addition of yeast to the saccharine liquid is not ordinarily made, but a portion of a previous fermentation is added to start the fermentation.

Distillation. The operations thus far described are merely preliminary. They differ from those employed in the two fermentation industries, wine and beer making, in that in preparing the liquor for distillation the fermentation process is carried to its furthest limit in order to produce the greatest possible amount of alcohol. The liquid thus prepared for distillation is technically known as the *wash*. The *still* is the apparatus in which the wash is reduced to vapor and then condensed. In its oldest and simplest form the still consists of a copper vessel, provided with a closed head, connected with a spiral tube, called the *worm*. The latter is placed in a refrigerator, or closed, chamber, through which cold water is constantly passing. When heat is applied at the still, the spirit begins to rise in vapor, along with more or less steam; these vapors pass through the worm, become condensed by the cold, and drop or trickle down into the receiver. The product of the first distillation in a simple still is a weak and impure liquid technically known as *low wines*. This is then redistilled at a lower temperature to deprive it of the water and of the fetid oils which have passed with the alcohol.

In 1801 the first great improvement in dis-

tilling was invented by a workman of Montpellier named Adam. By making the vapors rise from the still through a series of winding passages, maintained at a determinate degree of heat, and deposit part of the water and other impurities, he was able to obtain from wine a spirit of any required degree of purity at one operation. This device was applied by Pistorius to the distillation of washes made from grains. Within recent years many inventions have been made to produce the purest and strongest alcohol at the lowest possible cost. Sadtler divides the different forms of distilling apparatus into five general classes: 1. The simple stills already described, with worm condenser heated by direct firing. 2. The simple stills with closed "wash warmer." This is a device for saving fuel by causing the pipe containing the hot vapors on their way to the refrigerator coil to pass through a vessel containing the wash. Thus the wash is heated to a considerable degree before it enters the still at all. 3. Stills with rectifying wash warmer. This is a device invented by Dorn, in which the vessel through which the vapor pipe passes is divided into two compartments by a sheet of copper. The upper and larger compartment serves as a wash warmer. Through it the tube conveying the vapors from the still passes into the lower compartment, where at first the distillate is condensed. But as the wash is warmed by the vapors from the still, the distillate in this compartment gives off alcoholic vapors which pass on and are condensed in the worm, while the watery portion is allowed to run back into the still. This rectifying action can be increased by introducing two or more chambers between the still and the final condenser. 4. Stills with wash warmer, rectifying and dephlegmator apparatus for intermittent working. 5. Stills with similar apparatus for continuous working. A dephlegmator is an apparatus for partially condensing the vapor by means of metallic diaphragms. The vapor, coming in contact with these metallic sheets, is chilled, and the watery portion, which condenses most readily, separates and flows back, while the alcoholic vapors pass on through the pipes to the condenser. The Pistorius apparatus, already referred to, is an intermittent dephlegmator. The original invention has been improved successively by Gall, Schwartz, and Siemens, and is much used in Germany in making potato spirit. Examples of the fifth class of stills, those with a continuous dephlegmator apparatus, are the Coffey still, used in England for making grain spirit, and the Savalle still, used in France in distilling brandy. The Coffey still is particularly well adapted to the manufacture of what is known as "silent spirit," i.e., a spirit which is very strong and pure, but nearly destitute of flavor. For the manufacture of beverages it is not so well fitted because it removes, along with other impurities, a large proportion of the volatile oils which give them their peculiar flavor. For the principles involved in the process see DISTILLATION; EVAPORATION; BOILING POINT.

Purifying the Distilled Spirit. If alcohol and water were the only substances that pass over in distillation, all spirits, from whatever source, would be the same. But, except to a partial extent in the Coffey still, this is not the case. Brandy, rum, and whisky owe their distinctive flavors to essential oils derived from

the grape, from sugar, or from grain. Other impurities also pass over which are unpleasant and unwholesome. The mellowing effect of age upon spirits was formerly said to be due to the evaporation or spontaneous combustion of these oils, but is more probably due to the oxidation of the essential oils or flavoring principles. Newly distilled spirits are in general fiery and unwholesome. The process of removing the impurities from the spirit, by fractional or repeated distillation, is known as *rectifying* the spirit. The spirit that is first condensed, in rectifying, is crude and milky. Next comes the clear alcohol, which is caught separately. Last of all comes a weak spirit called *faints*, which is returned to the still. Certain impurities which give a bad flavor to the spirit cannot be removed by distillation. Several chemical methods have been proposed for their removal, but the method usually employed is to filter the alcohol, diluted with equal parts of water, through wood charcoal and then redistill. A process which has been used experimentally consists in mixing the diluted spirit with petroleum and agitating the mixture. The petroleum has the power of withdrawing the fusel oil from the mixture. Absolute or anhydrous alcohol cannot be obtained by distillation. (See ALCOHOL.) Rectified spirit of wine is the most concentrated alcohol producible by ordinary methods of distillation. The rectified spirit of the British Pharmacopeia has a specific gravity of 0.834 and contains 85.65 per cent alcohol by weight. The alcohol of the United States Pharmacopeia has a specific gravity of 0.816 and contains 92.3 per cent by weight. Proof spirit is a term applied to alcohol which conforms to the standard of the excise laws of the United States and England. English proof spirit has a specific gravity of 0.91984 and contains 49.24 per cent by weight. United States proof spirit has a specific gravity of 0.93437 and contains 42.7 per cent by weight. Alcohol is lighter than water (as 793 to 1000), and thus the lighter the liquid, the purer it is. The quantity of distilled spirits produced in the United States as stated by the Commissioner of Internal Revenue averages about 185,000,000 gallons per annum, of which about 140,000,000 gallons is consumed in the United States.

Beverages Made from Rectified Spirit. Whisky, brandy, and rum are distilled liquors used directly as beverages, being naturally flavored with aromatic substances derived from the materials from which they are prepared. But much of the distilled liquor produced is in the form of silent spirit, and is used to fortify wines and to arrest fermentation in them at any desired stage, and in the manufacture of factitious beverages generally. There is a large class of alcoholic beverages which are made by mixing with alcohol or brandy various aromatic substances. These distilled spirits are discussed under LIQUORS.

DISTILLED WATER. Water obtained by subjecting ordinary water, which contains more or less nonvolatile matter in solution, to a process of evaporation and by condensing the vapors in a separate vessel. Evidently, distilled water can contain no fixed matter, although it may and usually does hold volatile matter in solution, such as organic gases, ammonia, carbon-dioxide (and therefore also ammonium carbonate), ammonium nitrite, etc.—all these, to be sure, in very small quantities. To free distilled water from such impurities, it is acidified, say, with sulphuric acid, and a small amount of potassium permanganate is added; this acid solution is boiled, and the steam is caused to pass through another lot of distilled water, which contains an alkali (say, caustic potash) and again a certain amount of potassium permanganate, and which is kept hot; the steam is next filtered through a lot of glass wool to free it from droplets of the alkaline permanganate liquid which it may be carrying along, and finally it is condensed in a tin pipe cooler, as far as possible out of contact with the air. The first portions of the condensing vapor are rejected as not yet sufficiently pure, then a large fraction may be collected and kept pure for a time in vessels of insoluble glass (resistance glass). A sample of the purest water ever obtained was made by Kohlrausch in a vacuum established in sealed vessels of fused quartz. Absolute purity can, of course, never be attained.

Distilled waters is also the name applied in the manufacture of perfumes to the water containing the volatile aromatic principles of plants and flowers that pass over on distillation, as lavender water, rose water, etc.

DISTINGUISHED SERVICE ORDER. A military order instituted in 1886 by Queen Victoria for the purpose of rewarding army and navy officers. Appointments to membership are made by the sovereign, the head of the organization, for distinguished service in the field or on sea, specially mentioned in dispatches to the government. Its members wear a gold cross, bearing on one side the Imperial crown and on the other the initials V. R. I.

DISTORTION. See LIGHT, Lenses.

DISTRESS (OF. *destresser*, *destrecier*, *destroisser*, from Lat. *distringere*, to pull asunder, from *dis*- + *stringere*, to draw tight; connected with Lith. *stregti*, to freeze). An ancient creditor's remedy, common to all systems of primitive law, which consists in the seizure and detention by the creditor of his debtor's goods. It is one of the few survivals in our law of the practice of the personal enforcement of one's legal rights, without the intervention of the courts or the assistance of officers of justice. Originally applicable to a great variety of cases, it is now restricted to a limited number of situations, where its drastic character is mitigated by the relation of the parties to one another, and is strictly regulated by law.

Blackstone describes distress as "the taking of a personal chattel out of the possession of the wrongdoer into the possession of the party injured, to procure a satisfaction for the wrong

committed." Even in Blackstone's time, however, the scope of the remedy had been greatly narrowed, and he enumerates only two principal cases in which it was still available: (1) for nonpayment of rent or other duties annexed to the tenure of land; and (2) in the case of cattle of a stranger trespassing and doing damage (*damage feasant*) on one's land. It is still employed in these cases in England and in many of the United States. It was a remedy of feudal law, inseparable from fealty to the lord and incident to every service. It does not seem to be very popular, however, as a means of collecting rents, as it places the landlord in a better position than the other creditors. In several of the New England States distress has given place to an attachment on *mesne profits*. In New York and several other States it has been expressly abolished by statute, and in North Carolina it is held to be inconsistent with the spirit of the laws and not to exist in that State. The law of Louisiana permits the landlord to follow his tenant's goods for 15 days after removal from the premises. In general, in English and American law, the right to distrain is not limited to the goods of the debtor himself, but extends to any goods in his possession, whether belonging to him or not. But certain articles, as beasts of the plow, implements of trade, and any article at the time in personal use or occupation, have always been privileged from distress. So also where the owner, not being the debtor, is compelled by necessity to place his goods on the land, or where he does it for commercial purposes; as, in the first instance, the goods of a traveler at an inn, or, in the second, goods deposited in a warehouse on storage. Formerly the remedy of distress was limited to the seizure and detainer of the goods until the claim sought to be enforced was paid, the distrainer having no right to sell the goods, and the debtor, if he claimed the distress to be illegal, having recourse to an action of *replevin* (q.v.) for their recovery. Now, however, by statute goods taken under distress may often be sold after due advertisement at public auction and the claim of the distrainer satisfied out of the proceeds. In such a jurisdiction the character of the remedy by distress has been completely changed from a species of legal duress to a variety of attachment or execution. See LANDLORD AND TENANT; RENT.

DISTRIA, dĕ'strĭ-ă, DORA. See DORA D'ISTRIA.

DISTRIBUTION (Lat. *distributio*, from *distribuere*, to distribute, from *dis*-, apart + *tribuere*, to give, from *tribus*, tribe). The department of political economy devoted to the consideration of the rewards which are allotted to the several factors in production. It is a familiar axiom of political economy that land, labor, capital, and enterprise are united in the production of goods, and that to each is accorded a share of the product. Distribution studies the laws which govern the recompense of the several factors, and thus includes the law of rent, the

law of wages, the law of interest, and the law of profits. It is assumed that the four factors are in possession of four different sets of persons, although this is not essential to the formulation of laws. The union in one person of two of the factors would give to him a mixed reward, the components of which would be governed by different laws. There has been a tendency in recent years to draw more sharply than formerly the line between interest and profits, to distinguish between the owner of capital, who receives interest, and the employer of capital, who receives profits. This distinction is of increasing importance in the modern world, which, with its extension of credit, permits so large a share of the world's business to be carried on by borrowed capital, and places opportunities at the disposal of energetic and enterprising men which did not exist before. The area of discussion thus outlined represents one of the most controverted fields in economic writing. It has assumed prominence especially through the attacks of the socialists, whose contention is that the distributive process is radically at fault, and thoroughly inequitable. It is interesting to observe that as the discussion of exchange gave place in Adam Smith's writings to that of production, so later, in the writings of Malthus, Ricardo, and Mill, distribution became the leading element in economic discussion. The interest shifted somewhat from questions affecting the increase of the aggregate product to the consideration of the laws governing the distribution of the product. See **POLITICAL ECONOMY; INTEREST; PROFIT; RENT.**

DISTRIBUTION. In its most general sense in the law, the division of a surplus fund among those legally entitled to share therein. It applies equally to the division of a trust fund among the *cestuis que trust*, of the surplus assets of a bankrupt or insolvent among the creditors, of partnership property after payment of debts among the copartners, and of the surplus in the hands of an administrator of an intestate among those entitled, as next of kin or otherwise, to share it among them.

Distribution usually refers to the last of these, and the statutes which have been enacted in Great Britain and in the United States to regulate the distribution of an intestate's personal estate are accordingly known as statutes of distribution. The matter is one wholly of statute regulation at the present time.

Formerly the personal estate of one dying intestate passed at once into the hands of the bishop of the diocese, and the disposition made of it was determined by the ecclesiastical law, administered by the so-called "ordinary court" of the diocese. There seems originally to have been no provision for the payment of the debts of the decedent, and the bulk of the estate, after deducting some small provision for the widow and children, was devoted to the purposes of the Church (*in pios usus*). It was, however, as early as 1285, provided by statute (St. Westminster II, c. 19) that the ordinary should pay the intestate's debts just as an executor was bound to do, and in 1357 it was further enacted (31 Edw. III, st. 1, c. 11) that the ordinary should commit the administration of the intestate's goods to his next and most lawful friends. The jurisdiction of the ecclesiastical courts over the administration of decedent's estates, whether testate or intestate, continued in England till 1857, when it was transferred by Act

of Parliament to the newly created Court of Probate. It is now vested in the Probate, Divorce, and Admiralty Division of the High Court of Justice, instituted by the Judicature Act of 1873. In the United States separate courts of this character, known variously as surrogates' courts, probate courts, ordinary courts, and orphans' courts, have existed from the earliest period for the exercise of this jurisdiction.

The administration of decedents' estates includes (1) the payment of funeral expenses, of the costs of administration, and of the decedent's debts; (2) in the case of an executor, the payment of the legacies given by the will; and (3) in the case of either an executor or administrator, the distribution of the surplus, if any, among those entitled thereto under the statutes of distribution.

The feudal law of land, which confined the descent of real estate to a certain person or class of persons, making as heir of the intestate, had no application to the transmission of the personal estate. That was from the beginning distributed on a more rational and humane plan, due, in large part at least, to the mild influence of the canon, or ecclesiastical, law. It has been noticed that in the earliest period the right of the widow and children to share reasonably (*partes rationabiles*) in the decedent's estate was recognized. The same principles prevail to-day. There is a much less rigid classification of those who stand in the order of distribution than is the case in the law of the descent of land, and there is nothing like the feudal preference of the male to the female of the elder to the younger, of the whole to the half blood. In England the matter is regulated by the Statutes 22 and 23 Car. II, c. 10, and 1 Jac. II, c. 17, known as the Statutes of Distribution, and the order of distribution provided for by them follows closely that of the early law to which reference has been made. Similar statutes have been enacted in all of the United States, but these, though governed by the same principles and alike in their general outlines, vary considerably in detail. In general it may be said that if a man die, leaving a wife and children, one-third of the personal estate goes to the wife and the remaining two-thirds to the children. If there be a wife and no children, the wife takes one-half, the other half going to the next of kin of the deceased. If there be children and no wife, the children take the whole estate to the exclusion of other kindred. In England and in many of our States the position of a surviving husband is better than that of a surviving widow. The old common-law rule, that the husband is solely entitled to the personal estate upon the death of the wife, has been generally abrogated in the United States where there are also surviving children, and in many of the States his position has been completely assimilated to that of the wife. For a more detailed and exact statement of the order of distribution of intestate's estates, the reader is referred to the statutes of the several States. See the articles on **ADMINISTRATION; DESCENT; EXECUTOR**; and the authorities there referred to; and also Stimson's *American Statute Law*, vol. i (Boston, 1886).

DISTRIBUTION OF ANIMALS, or **Zoö-GEOGRAPHY**. Knowledge of the geographical distribution of animals, and their faunal relations past and present, constitutes a very important

part of the science of zoölogy. An animal's environment exerts a formative influence upon its character and structure. . . . of its habitat and that of its species, together with such changes as the area and range may have undergone, is therefore essential to a full understanding of the natural history of any kind of animal or animals.

Conditions Controlling Habitat and Range.

Some animals are fitted to dwell wholly upon land, others in water. The aquatic animals are, further, divisible into those of salt and those of fresh waters. The former have the oceans of the world open to them, yet few, if any, range through all seas; furthermore, the inhabitants of the surface of the sea differ from those of its bottom or deeper parts. Similarly, animals able to mount into the air and to fly abroad with apparent freedom are rarely cosmopolitan, and whole groups of these, as well as innumerable species and individuals, reside only within limited areas or along narrow lines of migratory travel. Fresh-water forms are likely to be restricted to separate lakes and river systems. Of the terrestrial animals none are now cosmopolitan, except those which have been carried by man to all parts of the world. (The introduced fauna of a region must always be distinguished from its indigenous fauna.) On the contrary, each of the present grand divisions of the earth has a characteristic fauna of its own, and often a whole family, order, or even subclass, belongs to one continent alone. Coincident with these restrictions and diversities, likenesses between widely separated lands are manifest; and representatives of a single group may be found in regions far distant from one another. To set forth these facts, to endeavor to account for them, and to develop their significance, is the province of *zoogeography*.

Limits of Dispersion: The Sea as a Barrier. Each kind of animal must have had a point of origin, whence it spread as it increased. Theoretically the expansion of a species would proceed equally in all directions, but actually this expansion has encountered barriers and restrictions that have confined and shaped habitats within certain areas, in some instances extremely wide, in others surprisingly narrow. What constitutes these barriers and restrictions? That depends in each case on the physical surroundings as related to the needs and abilities of the animal in question. It is plain that a species of fish that originated in or somehow became restricted to an inland water, e.g., Lake Baikal, could never spread beyond its shores save by accidental transplantation; while an able seagoing fish may wander indefinitely, so far as mere room is concerned. Among land animals space for expansion, then, is of prime importance. Here the firmest bounds are set by the sea. Any considerable breadth of water, and especially of salt water, is uncrossable except by rare and extraordinary accident; and even then a pregnant female or a pair must be landed on the further shore in order to start a colony, which must, furthermore, find favorable surroundings in order to survive in the new locality. This accounts for the fact that mammals and terrestrial reptiles and amphibians are absent from oceanic islands. Continuity of land, then, is necessary to the spread of a terrestrial species; and when species are found in regions now widely separated, as

shown that such regions were formerly connected by lands now submerged. Conversely, the characteristics of the present fauna of such comparable regions assist the geologist to determine when the connection was finally broken.

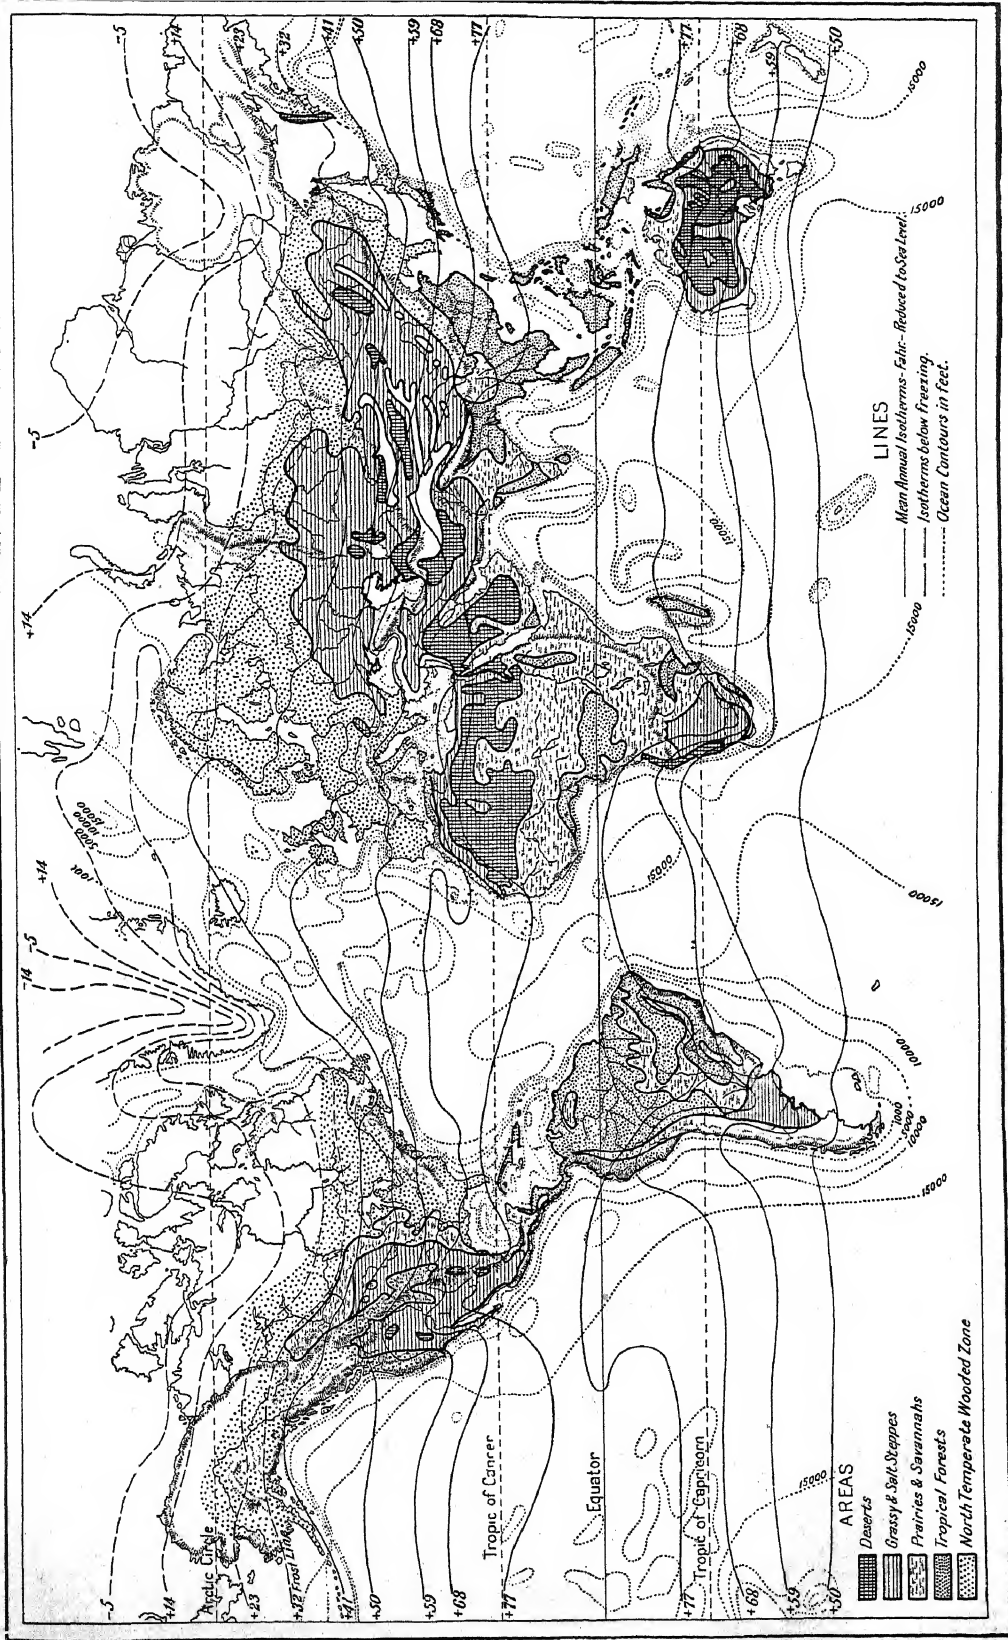

Insular Faunas. The faunas of most islands near continents date back to the time when these islands were a part of the adjacent mainland or were separated from it only by narrow straits. The explanation of the broad and conspicuous disparity that exists between the faunas of such large islands as Australia and Madagascar and those of Asia and Africa respectively is accounted for by the evidently very ancient date at which they became dis severed. "It is evident," remark Flower and Lydekker, "that Australia has been isolated from the Asiatic continent from some very remote geological epoch, at which period it is probable that monotremes and marsupials were the dominant, if not the sole, representatives of the mammalia then existing. Consequently Australia has never been able to receive an influx of the Eutherian orders, which have probably swept away all the marsupials except the small American opossums from the rest of the globe. Again, the large island of . . . which has a fauna of an African type, but still very markedly different from that of the mainland, may be considered to have been connected with the latter at a time when the Eutheria had become the dominant forms, but has been separated for a sufficiently long period to have enabled a large number of its species and genera to have become distinct from those of the adjacent continent. Similarly there is evidence to show that South America was probably cut off for a considerable period from the northern half of the American continent, in consequence of which its lowly organized fauna of Edentates were enabled to attain such a remarkable development in the later . . . periods. Consult Wallace, *Island Life* (New York, 1902). See ISOLATION.

"The above instances [and their converse, exemplified by the identity of insular and continental faunas where a land union is known to have existed lately] are sufficient to show . . . how largely the present distribution of mammalian life is bound up with the past history of our globe. We must, however, not omit to mention another very important agency of past times which has likewise had great influence on the present distribution of the various faunas of the Northern Hemisphere. This is the so-called Glacial epoch, which took place immediately before the establishment of the present state of things, and appears to have been the cause of the extinction of many of the larger mammalian types which formerly inhabited Europe."

But while many species have had a far wider distribution in past ages than now (and in a general way a widely distributed form may be regarded as an old form), many species seem never to have expanded much, some being limited to a short stretch of coast, or a single river valley, or to a certain mountain or island.

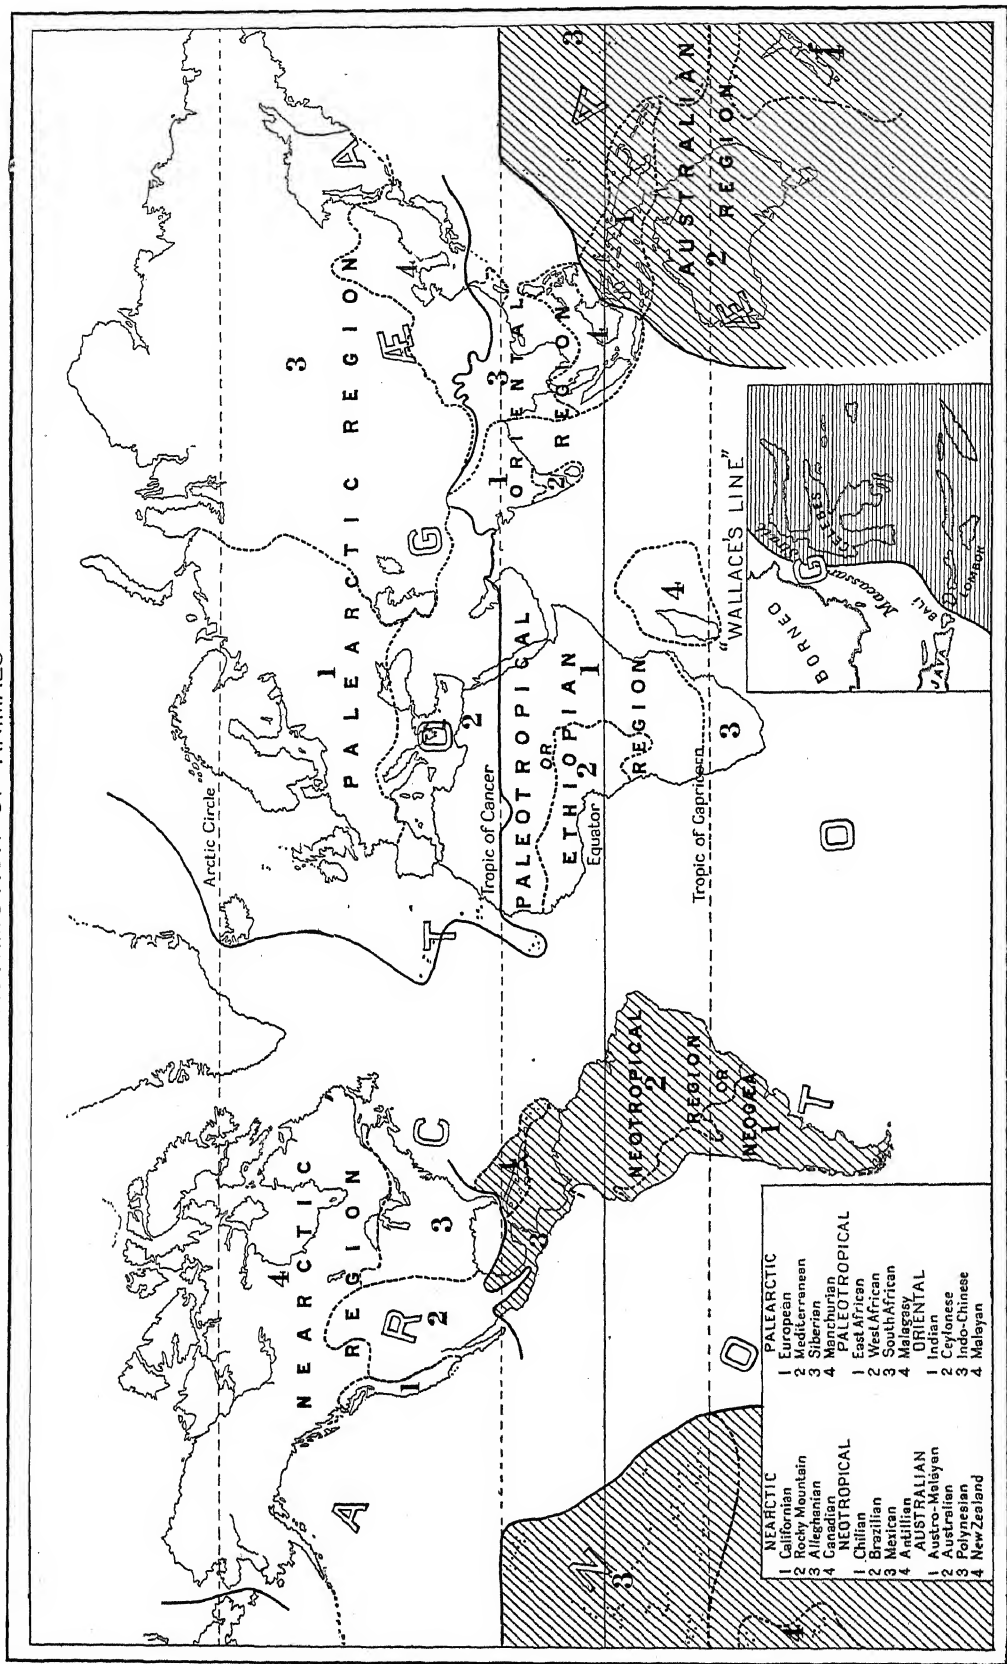

Deserts, Mountains, etc., as Barriers. Other barriers than the sea, therefore, have been effective in impeding the spread of crescent varieties, species, and groups. Most prominent among these is a desert region. The Sahara cuts off almost completely the fauna of Europe from that of Africa; and the continuation of

DISTRIBUTION OF ANIMALS

PHYSICAL FEATURES OF THE EARTH AFFECTING DISTRIBUTION OF LIFE

DISTRIBUTION OF ANIMALS

ZOOGEOGRAPHICAL REGIONS

divides the northern Asiatic animals from the southern in a most emphatic way. Similarly, the fauna of North America stops and that of the southern continent begins where the plains and table-lands of Arizona and northern Mexico interpose a waterless, scantily planted space of semidesert and sterile hills, uninviting to either set of animals as a whole, yet invaded by both.

Long and lofty mountain ranges stand next in importance, probably, as physical barriers, but this is more marked in the warmer than in the cooler parts of the world, since animals accustomed to the torrid conditions of tropical plains cannot or will not endure the cold and lack of customary food encountered even on the passes, and so do not cross over the highlands. The mountains of North America seem to make less difference with the distribution of our animals, as between the Atlantic and Pacific slopes, than does the central-plains area; and that of Europe has been little affected by the presence of mountains. The Atlas Range is more marked as a boundary, but that is because of the neighboring desert; and similarly the great Central-Asian ranges are part of the lofty, cold, and arid region which as a whole forms probably the most effective inland barrier in the world.

Deep and broad rivers or straits of the sea may interrupt the spread of many species. The Hudson seems never to have been crossed by the opossum, which could neither get over nor around it. The Mississippi put an end to the eastward progress of the jaguar along the Gulf region, and much smaller rivers might stop many other creatures, such as most monkeys (which are unable to swim); yet none would prove a barrier to flying or amphibious animals, and many serve to extend hundreds of miles the range of aquatic and semiaquatic ones.

Frequently, however, neither these nor various other "barriers" that might be mentioned seem to have prevented the growth of species which nevertheless are scant in numbers and extremely restricted in area of range. The blaubok (q.v.) of South Africa was unknown beyond a single valley and has become extinct. This is a sharp example of many puzzling cases where probably the restraining influence has been competition. Each locality supplies food, water, and shelter for only a certain quota of animals. The ablest and best-fitted in each class for that region will get the most out of it and will increase and spread. The "struggle for existence" is everywhere a real daily fight for space and subsistence, and the weakest will gradually succumb or become prisoners within areas so peculiarly favorable to them that there they are able to hold their own. The powerful and gregarious cattle long ago forced the sheep to keep to the mountain pastures. Active enemies must also be considered, certain animals not being able to exist in the same territory. A river infested with crocodiles might forever prove uncrossable for small quadrupeds that otherwise might soon pass over it. The faunal distinctions between forest and prairie, mountain and plain, diurnal and nocturnal methods, are effects of enmity as well as of competition.

Climate and Altitude as Factors. Of climate as a determinant in geographical distribution, perhaps too much has been made in the past. Climate, within its extremes, seems influential upon animal life mainly as cold or prevailing drought affects the higher forms of vegetation (see DISTRIBUTION OF PLANTS), and

consequently the food of herbivorous and insectivorous animals. Such species as can take a varied fare, and can by migration, storage of food, or hibernation, escape or provide against storm and scarcity, defy climatic bounds. The big cats and bears range from torrid jungles to snowy mountain tops and subarctic latitudes. Transplanted species frequently flourish in climates the opposite of that to which they are native. In a general way, nevertheless, similar animals are found in similar climates, and within the larger regions lesser faunal divisions often conform closely to isothermal belts—a fact more noticeable in North America than anywhere else. Here, too, comes in the so-called "vertical" distribution of life observable in high mountains, where various altitudes exhibit an animal and plant life identical with or similar to that of northern latitudes, where a corresponding average of temperature prevails. Thus mountain ranges lying north and south carry far towards the equator along their cool ridges species which exist near sea level only in high altitudes. Our bighorn, once numerous along the Rockies south to New Mexico, is an example of this feature; and the guanaco of Patagonia, following the Andes north to the equator in Ecuador, is another. Terrestrial life is everywhere most plentiful near sea level and in warm regions and becomes more scanty as the poles are approached or mountains are ascended. Mountain tops, however, frequently form refuges for animals elsewhere known only in subarctic regions, which were left on their lofty and now isolated homes from the time when semiglacial conditions prevailed over the whole district.

Distribution within the Sea. Related to climatic influences on land are those conditions in the sea which set invisible bounds to the spread of most marine animals, even when apparently at full liberty to go anywhere. A few species of big whales, sharks, and predatory fishes are known in all parts of the oceanic world, and even individuals are often very far-ranging. Some others are spread throughout all the northern seas, or all the southern, as the case may be; but of tropical marine animals very few are common to both the Atlantic and the Pacific. On the contrary, the distribution of marine animals of every sort exhibits local restriction as fully as does that of land animals. Marine animals may be divided into three classes as relates to the present theme, viz., the Littoral Fauna, Pelagic Fauna, and Abyssal Fauna. To the first belongs the crowded life of the shore region, where the rocks and forests of kelp, coral reefs, and natural bottom from high-water mark down to 100 fathoms or so of depth, are the home of a vast number and variety of fixed and moving creatures of the lower orders, and a host of higher arthropods, fishes, and cestaceans which live among or upon them. These vary with the conditions. They are most abundant in the tropics and decrease towards the poles. Drifting sand and mud are nearly barren, but rocky shores are populous. Currents of cold water affect a coast unfavorably, while warm currents bring and sustain many species. Thus, physical and climatic conditions influence the amount and distribution of shore life beneath the water much as they do that above it.

The "pelagic" fauna includes those animals which habitually dwell upon or near the surface of the open ocean, visiting all parts of it. They

may be able to swim actively and so move at will here or there, and such form the class "nekton," or, like the jellyfishes and salps, may only float and be drifted about by winds and currents (the class "plankton"). Even here, however, certain species and groups are to be gathered only in certain parts of the sea; and their range seems to be limited mainly by factors of temperature. Thus, the fauna of the Gulf Stream is distinct from that of the Atlantic for a considerable distance north of Florida.

Bathymetric Distribution. A new element enters into the question of the distribution of life in the sea, viz., variation in depth. This is comparable, in reverse, to hypsometric distribution, or that according to height above sea level. Layers of animal life, as it were, may be observed from the shore line to the greatest explored depths. Most of the creatures to be found between tide marks are absent or rapidly decrease below a few fathoms, while many rarely approach the shore, but are numerous on bottoms covered by 100 to 300 fathoms of water. Another zone belongs mainly or exclusively below that; and the globigerina ooze (q.v.), covering the ocean bottom with grayish mud in most parts of the world, from 400 fathoms down to about 2000 fathoms, has a distinct fauna of its own. Below 2500 fathoms the sea bottom is formed of red clay, in which shells are absent, having apparently been dissolved during their descent to the greater depth. Even here, however, is found an abyssal fauna chiefly of fishes, "often of a very grotesque appearance."

This bathymetric distribution, from the 100-fathom line down, depends upon the factors of temperature and density. The former would be influenced by the ocean currents, and the animal life in the path of an influx of water from the polar regions would be different from that in the path of a warm current. The abyssal fauna is one habituated to such a degree of cold as would instantly kill much of the littoral or surface fauna. In addition to this powerful localizing influence, that of density, increasing with depth of water, is supreme as limiting the upward and downward range of animals habituated to a certain stratum, i.e., to a certain average degree of water density. Surface animals would be smothered at a mile of depth; and those brought by dredges from the abysses are often found to be burst to pieces by the expansion of the air in their cavities and tissues. Thus, vertical as well as horizontal limits are set in the sea. Too little is known of the abyssal fauna to say whether its members are world-wide or restricted to local areas; but, as the conditions in the deep ocean basins are nearly uniform and undisturbed, it is probable that all the life is widely distributed. See DEEP-SEA EXPLORATION.

Fresh-Water Life. The fresh-water fauna has certain characteristic features, and is divided into "fluvatile" forms, inhabiting streams and rivers, and "lacustrine" forms, inhabiting large lakes, where, as in the sea, the life is divisible into "littoral," "pelagic," and "deep-water."

Dispersion. The slow or rapid spread of a species from its point of origination will depend upon its powers of locomotion and its adaptability to new circumstances. In the mammalia this is a matter of walking and swimming. Some are excellent swimmers, and the great spread of the tiger throughout the Orient is

mainly due to his natatorial ability. The faculty of flight has made bats more nearly cosmopolitan than is any other order of mammals. The wings of birds and insects give them a superior means of dispersal; flightless birds are, and always have been, much more circumscribed than the fliers. Reptiles and amphibians are poorly provided with means of locomotion and are often very sluggish, while fresh-water fishes, except anadromous ones, usually dwell in confined waters. As for the mollusks, lower orders of insects, worms, and small sedentary animals of the shores, their principal, and often sole, resource is in the spread of their eggs or free-swimming larvæ. Mechanical aids, however, render important assistance in the dispersal of certain species, as is the case with so many plants. Land animals, large or small, frequently float across spaces of sea on ice cakes or driftwood, and some islands have undoubtedly been colonized in this way; yet it is a remote chance to trust, for unless a pair or a pregnant female were thus transported, no gain would result. Parasitic animals are carried about by their hosts. Small crustacea and mollusks may be carried great distances by wind, or by adhering to the feet of birds. Infusoria, the eggs of rotifers, and other microscopic forms may be transported in the dried condition by the wind. Darwin brought forward much curious information on this subject in the second volume of his *Origin of Species* (London, 1882).

It will be seen that the varying abilities among the different groups of animals would make their distribution very different from one another. Salt water is a poison to larval amphibians, while birds may fly across more than 1000 miles of sea space. Mammals may run about rapidly, while the reptiles and small invertebrate creatures must creep slowly or not at all. Finally, marine animals occupy an area and medium entirely different from that held by terrestrial animals. These variations must be borne in mind in . . . reduce to scheme and system the . . . phenomena of zoögeography.

Faunal Regions. Heretofore we have been considering only the dispersion and restriction of a species. But, as a rule, several kindred co-exist in any given area, and these usually differ in their range, while occasionally a species of the same genus is to be found somewhere else, entirely disconnected from its fellows. This shows that the geographical area covered by a genus is greater than that of a species; and, carrying the same inquiry further, it appears true of families, orders, and classes. The larger the group in the scheme of classification, the wider its geographical area. To ascertain and record the spread, past and present, of the groups of animals is the business of zoögeography. The earlier students drew up a map in which they confidently set apart a series of realms, provinces, and subprovinces. A vast amount of such information had been tabulated by Sclater, Darwin, Schmarda, Murray, and others previously to the publication, in 1876, of Alfred Russel Wallace's monumental work on the subject. Wallace, following Sclater (1857), divided the globe into six grand "regions," each characterized by groups of animals absent from, or very scantily represented in, any other. These were:

Palearctic Region.—Europe, Africa north of the Sahara, and Asia north of the Himalayas.

Oriental Region.—India, Malaya, southern China, Sumatra, Java, Borneo, the Philippines, and included islands.

Australian Region.—Australia and the islands north of it from Celebes eastward, New Zealand and the South Sea archipelagoes. This was divided from the Oriental region by Wallace's line—a name gracefully given by Huxley in 1868 to the demarcation discovered by A. N. S. Wallace, London, 1859; *Proceedings Zoological Society*, ib., 1863; *Malay Archipelago*, London and New York, 1869), which passes along the narrow straits between the Philippine and Sulu islands, and southward between Celebes and Borneo, Lombok and Java. He found the birds and mammals strikingly different on opposite sides of this line of deep channels. "The great contrast between the two divisions of the archipelago," he informs us, "is nowhere so abruptly exhibited as in passing from the island of Bali to that of Lombok, where the two regions are in closest proximity. . . . The strait is here 15 miles wide, so that we may pass in two hours from one great division of the earth to another, differing as essentially in their animal life as Europe does from America. If we travel from Java or Borneo to Celebes or the Moluccas, the difference is still more striking. In the first the forests abound in monkeys of many kinds, wild cats, deer, civets, and otters, and numerous varieties of squirrels are constantly met with. In the latter none of these occur, but the prehensile-tailed cuscus is almost the only terrestrial mammal seen. . . . The birds, which are most abundant in the western islands, are woodpeckers, barbets, trogons, fruit thrushes, and leaf thrushes; they are seen daily and form the great ornithological feature of the country. In the eastern islands these are absolutely unknown, honey suckers and small lories being the most common birds; so that the naturalist feels himself in a new world."

Ethiopian Region.—Africa south of the Sahara, and Madagascar.

Nearctic Region.—North America and the elevated central region of Mexico.

Neotropical Region.—South America, Central America, and the West Indies.

Each of these regions was divided into four subregions or "provinces." In Africa, Cape of Good Hope and the southeast coast formed a province, the Congo and Niger basins together another, Madagascar and the Mascarene Islands a third, and all the rest of the continent south of the Sahara a fourth. In North America, all Canada north of Lake Huron and the Saskatchewan was one province, the eastern United States as far as the central dry plains formed a second, the Rocky Mountain country and "great basin" a third, and the Pacific coast the fourth. And so on. For the faunal characteristics of each of these regions, see the articles under their names; also Holarctic Region; NEOGÆA; NOTOGÆA.

Arctogæa and Notogæa. The apportionment above sketched has proved too artificial. The propriety of separating North America from Europe and Asia was soon disputed, and they were united by various authorities in a single circumpolar region called Holarctic (or Periarctic). The equatorial countries, mostly separated by oceans, cannot be so easily combined, and for some time the only serious change in the classic arrangement was the erection of the

New Zealand group from secondary to primary rank. Much is to be said in favor of this movement, but it seems not to be generally acceptable.

As knowledge of both the living and fossil animals of the southern continents and islands has increased, and criteria have become largely available outside of the groups of birds and mammals upon which earlier conclusions were mainly based, it becomes more and more apparent that even these regional distinctions are vague. The best opinion at the opening of the twentieth century, following Huxley (1868), held that only two prime regions might be recognized in zoögeography—*Arctogæa*, a northern world, and *Notogæa*, a southern world. These names, however, are not precisely descriptive. *Arctogæa* includes not only the whole Northern Hemisphere, but also Palearctica (Africa, India, and the East Indies as far as Wallace's line). *Notogæa* is formed of South and Central America and Australasia. Within these primary realms the old subdivisions seem to hold pretty well, except that North America does not seem separable from Eurasia, both now forming the single Holarctic region (q.v.) of recent students.

Lesser subdivisions must be determined independently, if at all, for each group under study. Nor have even the largest zoögeographical divisions hard and fast boundaries. They overlap and blend, forming transitional zones or debatable grounds. The stretch of mountainous deserts from the western Sahara to Manchuria is such a zone, where representatives of northern and southern faunas mingle, and where dwell many species not known elsewhere in either. The so-called "Sonoran" subregion (southwest United States to the highlands of Central America) is another borderland of debatable validity. The distinction between the Malayan and Australian subregions insisted upon by Wallace disappears entirely in respect to frogs and toads. In truth, the lesser subdivisions that have been so numerous and exactly marked off by specialists have no real existence. "They depend," to use Gadow's words (1902), "upon the class, or even order, of animals which we happen to study. The faunistic distribution of the Urodela is not that of the Anura, and both follow separate lines of dispersal, different from those of the various orders of reptiles, birds, and mammals. This must be so. There is no doubt that the distribution of land and water was totally different in the Coal age from what it is now. The face of the globe at the Jurassic age can scarcely be compared with the aspect which the world had assumed in the Miocene period. This leads to another consideration often neglected. We know that the various classes, orders, families, etc., of animals have appeared successively on the stage. A group which arose in the Coal age followed lines of dispersal different from one which was not evolved until Jurassic times, the post-Cretaceous creatures could not avail themselves of what assisted their ancestors, and vice versa. . . . Speaking generally, the older a group the more likely it is to be widely distributed. If it appears scattered, this may be due to extinction in intermediate countries, or to submergence of former land connections. . . . It is the morphologist who is ultimately responsible for the establishment of faunistic regions, not the systematist, least of all he who accepts an elab-

orate classification, and then mechanically, mathematically, by lists of genera and species, maps out the world."

DISTRIBUTION OF DISEASES. It is generally known that local conditions, such as climate, variation of temperature, the composition of the soil, elevation of the land above the sea level, distribution of water, and the character of the vegetation, combine with the peculiar habits of the people to determine the greater or less prevalence of certain diseases in the different regions of the earth. The science of nosography in this aspect did not receive much attention before the beginning of the nineteenth century and is still comparatively undeveloped. The importance of climate as a factor in the distribution of diseases is obvious. Yet certain diseases, as Egyptian ophthalmia, the pellagra of Lombardy, the beri-beri of Ceylon and the Malabar coast, and the elephantiasis of the Indian peninsula, appear to have no relation to climate, but are confined to certain well-defined districts. Tropical regions are the home of malarial fevers, cholera, and hepatic diseases. This is due in part to the damp soil and decaying vegetation, particularly in the river val-

leys, affording a breeding ground for hosts of biting insects, which convey the germs of these diseases. The yellow fever of the Mexican Gulf, though often aggravated by other conditions, doubtless originated primarily from this cause. In the more temperate zones typhus, typhoid, intermittent, and scarlet fevers are found. They are, however, for the most part, not so much endemic as epidemic and owe their . . . to the crowding of people together for warmth, with its consequent ready exchange of infection. In the Northern Hemisphere, north of the tropical zone, catarrhal diseases prevail, while in the corresponding zone of the Southern Hemisphere they are much less frequent. Intestinal catarrh prevails, however, to a considerable extent in some parts of the intertropical regions. In some cases hilly regions are ravaged by fevers, while in the intervening valleys fevers seldom occur. The cultivation of the soil sometimes essentially modifies the character of the malarial diseases. The destruction of forests often results in the introduction of diseases unknown before. Indeed, as a general rule, living vegetation tends to preserve health, while decaying vegetation is a prolific source of disease. Defective drainage, natural or artificial, is also a common source of disease, especially in cities. The personal habits of races and communities in respect to diet and cleanliness exert a wide influence upon the public health. Europe, on the whole, possesses the requisite conditions of health in greater perfection than any other quarter of the world. The rates of mortality from diseases of the lungs are greater in northern than in southern latitudes. This is illustrated by the prevalence of consumption in the northeastern portion of the United States. Fevers are more prevalent in the Southern than in the Northern States. Malarial fevers are dependent on the agency of mosquitoes for their spread, and are especially fatal in the southern regions of the country; they are infrequent, however, where pine forests abound.

DISTRIBUTION OF PLANTS, PHYTOGEOGRAPHY, PLANT GEOGRAPHY, or GEOGRAPHICAL BOTANY. That division of biological geography that deals with the distribution and with the causes of distribution of plants. The subject has been studied since the time of Linnæus, but its modern period dates from the works of Alphonse de Candolle and of Grisebach, about the middle of the nineteenth century. More recently the works of Warming, Drude, Engler, and Schimper have added much to our knowl-

edge of the subject. Phytogeography may be divided into two main heads: first, ecological phytogeography, which seeks to account for the distribution of *plant forms* (e.g., the forms peculiar to water plants, to desert plants, etc.) and the causes, mainly climatic and meteorological, of such distribution; second, floristic phytogeography, which has for its aim the subdivision of the world into floral regions and districts, and the study of the distribution of *plant species* in these regions, thus dealing with the species as units, and seeking to determine the geological and similar causes for plant distribution.

ECOLOGICAL PHYTOGEOGRAPHY

Schimper subdivides the world into tropical, temperate, and frigid regions, alpine districts, and the seas. Each of these divisions, especially the first two, is in turn redivided into formations. These formations, if determined by climatic factors, are termed climatic formations; if by local or soil factors, edaphic formations. For example, deserts and tropical rainy forests are climatic formations, their existence being determined mainly by the distribution of atmospheric moisture; on the other hand, the flora of a swamp or of a heath, being governed mainly by local soil factors, is spoken of as an edaphic formation.

Climatic Formations. In general, the climatic plant formations of the world belong to one of three types, viz., forests, grass lands, or deserts. This classification points to three great atmospheric factors—wind, moisture, temperature. Wind has acted as the great distributing agent, carrying seeds and spores from place to place. Moisture is not only necessary to the germination of seeds and the growth of plants, but its abundance or scarcity has a profound influence upon plant growth; the moist belt bordering the equator is as remarkable for the luxuriance of its vegetation as the arid districts—the great deserts of the world—under the Tropic of Cancer, are noted for their barrenness; barrenness proved, by oases at springs and by the results of irrigation, to be due mainly, if not solely, to the absence of water. The range of temperature in which plants will grow and reproduce varies widely with different species; some are capable of withstanding very low temperature, others very high, and in many instances experiment has proved that members of either group will fail under conditions favorable to members of the other. A fourth factor, light, must be considered. Light is as essential to the growth of green plants as are moisture and heat, but the amount necessary for individual species varies greatly. Some are able to thrive in even the dense shade of tropical forests; others are unable to exist except in direct sunlight. Again, the effect of the amount of light is well illustrated by the shortening of the period of growth required by cereals cultivated in the Canadian Northwest, due to the extra hours of sunshine during the growing season. Although, as yet, but little knowledge has been gained by experiment to aid in determining the exact nature of the influence of these factors on the distribution of plants, there is no room for doubt that such influences do operate. Between the equator and the poles, between the base and the top of a mountain, between the moist coastal districts

and the arid interiors of the continents, between the depths of a forest and the treeless plateau, there are gradual changes in the vegetation that mark the striking parallelism that exists between the distribution of wind, moisture, heat, and light, and the distribution of plants.

Edaphic Formations. As already noted, the edaphic formations are determined by local causes, mainly those which reside in the soil. Much dispute has arisen among authors as to whether chemical or physical causes are uppermost in determining distribution; dispute that obviously cannot be settled until knowledge based upon sufficient experimental data, at present sadly lacking in most instances, shall be gained upon this subject. It seems most in harmony with our present knowledge to hold with Warming that the water in the soil is the most potent factor in determining local distribution of forms. In passing from the centre of a pond to upland, plants may be encountered in more or less definite succession whose structures bear close relations to the water supply. Forms, such as duckweed, which have no root-anchorage, but drift with the wind on the surface of the water, have large air-containing chambers, which greatly increase the transpiring surface. A similar open structure is observed in water plants whose roots are anchored on the bottom and in those marsh plants growing on the margins, but as the ground becomes more and more dry, the open structure which favors transpiration gradually disappears, and devices for checking transpiration take their place. Careful study has shown clearly that there are other elements, however, which must be considered. For example, the vegetation of an undrained swamp is radically different from that of a similar moist situation on a river margin. Doubtless certain conditions of drainage enter here to cause the difference in plant forms. Again, factors which are in a certain sense atmospheric often have a local influence. Plant forms found on the north side of a hill frequently differ from those on the south side because of possible differences in exposure to moisture and wind as well as to different exposure to the sun. All of these factors may, so to speak, be regarded as edaphic, since all are similar in being local rather than climatic. In general, the edaphic formations may be subdivided into *coastal formations* or societies, and *inland formations* or societies. The coastal societies may be destructive, as illustrated by the erosion of cliffs where they break down the rocks; or they may be constructive, as illustrated by swamps and beaches, where they act in building up the land. Inland societies may be divided into those associated with river activities and those that are not. In the life of a region all areas will ultimately be worked over by rivers, so that the stages which are not associated with rivers may be regarded as more or less temporal. The ultimate condition of a region is that of the base level—the flat lowland resulting from completed erosion—towards which the other conditions are approaching, and which in a favorable climate will be covered in most instances by a mesophytic forest.

FLORISTIC PHYTOGEOGRAPHY

In a general presentation of the distribution of plants the algæ, fungi, liverworts, and mosses may be dismissed with a few statements. These

groups are found everywhere. It should be noted, however, that the brown algae (kelps) reach their greatest development in the colder waters, and that the lichens and mosses are more abundantly displayed in temperate and arctic than in tropical regions.

Pteridophytes. In number the ferns so far exceed all other pteridophytes that they may be taken as representing the group. Their greatest display is in the tropics, where they often assume the tree form and develop extraordinarily large fronds. In temperate regions they are neither abundant nor conspicuous; while in arctic and alpine conditions they are hardly at all represented. It will be noted that the distribution of ferns is almost in direct contrast to that of mosses.

Gymnosperms. In presenting the distribution of gymnosperms the three principal living groups must be considered separately. The cycads are strictly tropical forms, being distributed about equally between the Oriental and Occidental tropics, the genera for the most part being definitely restricted to certain regions. For example, while the genus *Cycas* ranges throughout the Oriental tropics, and *Zamia* throughout the Occidental tropics, one genus is strictly Australasian, two are African, two Mexican, and one is Cuban. The conifers form the largest group of gymnosperms, and their distribution contrasts sharply with that of the cycads, being entirely absent from the tropics and massed in the temperate regions, especially of the Northern Hemisphere. The broad tropical belt separating the conifers of the north and the south temperate regions is traversed in only two places, viz., by a southern genus, *Podocarpus*, that reaches China and Japan through the East Indies, and by a northern genus, *Libocedrus*, that reaches into temperate South America by way of the Andes. By far the greatest conifer display, with respect to number of genera and of species, is found in the districts that border the Pacific Ocean, the chief areas being the China-Japan region, the Australasian region, and western North America. The most remarkable displays of endemic genera are in the China-Japan and the Australasian regions, the former containing eight such genera and the latter five. The other regions of endemic genera are North America, with its redwood (*Sequoia*), and bald cypress (*Taxodium*), and South America, with a peculiar genus in the mountains of Peru. Throughout the north-temperate regions the dominant and widely distributed genera are the pine (*Pinus*), juniper (*Juniperus*), fir (*Abies*), spruce (*Picea*), cypress (*Cupressus*), and larch (*Larix*); the order of citation indicating their relative abundance. There is also a remarkable pairing of western North America and eastern Asia in the display of certain genera, no less than six genera being common to these two regions and occurring nowhere else. The distribution of the conifers of the Southern Hemisphere is modified by the temperate conditions that occur in three great isolated areas. The dominant genus, *Podocarpus*, the "pine" of the Southern Hemisphere, is the only one represented in all of these regions; but in the display of certain other genera there is a pairing of the continents, the Australasian region always being one member of the pair, and, with one exception, South America the other member. In conifers, therefore, there is much more in

common between Australia and South America than between either of them and Africa. The Gnetales, constituting the third prominent group of gymnosperms, embrace three genera of very distinct characters and distribution. *Ephedra* occurs under both tropical and temperate conditions in the arid regions of Mediterranean Europe and Africa and adjacent Asia and in arid parts of America; *Gnetum* ranges through the moist tropics of both hemispheres; while the monotypic *Welwitschia* is narrowly restricted to certain extremely arid regions of western Africa.

Angiosperms. The immense number of angiosperms, or true flowering plants, makes their distribution a difficult subject to present in a few statements. It must be understood, therefore, that the following presentation is very general, considering large masses of plants rather than species or even genera. It must be remembered, also, that in general the conditions of plant life are most favorable in the tropics, where there is apt to be massing; and that under arctic conditions, which are very unfavorable, vegetation is apt to be scant. The three prominent groups of angiosperms, viz., the monocotyledons and the two divisions of dicotyledons (Archichlamydeæ and Sympetalæ), must be considered separately.

Monocotyledons. The most conspicuous general facts in connection with the distribution of monocotyledons are as follows: *Cosmopolitan groups.*—Four great families (grass, sedge, lily, and iris), including almost 10,000 species or about one-half of the monocotyledons, are world-wide in their distribution. This means that they have succeeded in adapting themselves to every condition of soil and climate possible to flowering plants; and in this feature the grasses easily lead not only monocotyledons, but all other seed-bearing plants. Beyond the natural massing towards the tropics, the distribution of these four families is fairly uniform. *Aquatic Plants.*—The monocotyledons include an unusual number of purely aquatic families, although among the other families the number of water species is remarkable. A distinct water habit is associated with world-wide distribution, not merely of families, but often of species. For example, the common cat-tail rush (*Typha*) of the United States is also found in Europe, Asia, and Africa. But it must be noted that although these aquatic families of monocotyledons are world-wide in their distribution, their number of species is remarkably small, being about 180. In contrasting this with the 10,000 species of the four terrestrial families above referred to, it becomes evident that the relatively uniform conditions of aquatic life do not result in the evolution of species as do the extremely varied conditions of terrestrial life. *Tropical Plants.*—The remarkable massing of monocotyledonous families in the tropics, far in excess of any normal ratio of tropical increase, makes it evident that the monocotyledons as a whole must be considered the leading tropical group of angiosperms. This tropical massing is indicated by the fact that, excluding the 10 families of world-wide distribution, 23 out of the 33 remaining families are tropical. It is even more strongly indicated by the fact that, excluding the 10,000 species that were noted above as belonging to the four world-wide families, all but a few hundred of the remaining 10,000 are tropical. The approxi-

mately equal distribution of tropical forms between the two hemispheres is noteworthy. This is true not merely in the number of families, but in genera and species as well. There are four or five families peculiar to the Orient, seven or eight peculiar to the Occident, and perhaps 10 or 11 common to both. The palms may be taken as an illustration of the distribution of tropical monocotyledons. There are approximately 1000 species of palms, almost exactly divided between the two hemispheres, but not a single native species is common to the two. The genera are about 130, approximately, 75 of them being Oriental and 55 Occidental, the apparent inequality being accounted for by the more numerous monotypic genera in the Orient, due to the larger and more broken tropical area, but the two hemispheres have not a genus in common. The family is divided into great tribes, but not one of these tribes is common to the two hemispheres. These tribes are groups of genera on the way to becoming families and by some are regarded as such already. The palms thus notably illustrate the effect of long separation in plant adaptation to continental diversities, temperate and arctic conditions long having cut off the connecting land between the tropical regions of the two hemispheres, which are believed to have been united in prehistoric times and between which plant and animal forms could migrate. The preponderance of epiphytic forms in the Occidental tropics is probably associated with the great development there of the rainy tropical forest. The two great epiphytic groups of flowering plants are bromeliads and orchids, both monocotyledons, the former family being restricted to the Occidental tropics, and the latter much more abundant there than in the Orient. The general adaptation of the monocotyledons to tropical conditions is emphasized by the extreme dearth of monocotyledonous species in arctic and alpine regions, only the few species belonging to the four families of universal distribution being present. The feeble representation of monocotyledons in the S. S. outside of the tropics is . . . only four small families belonging exclusively to this region; and in Australia, a continent prolific of endemic forms among gymnosperms and dicotyledons, there is but a single endemic family of monocotyledons, containing only four species. A family of most peculiar distribution is the Stemonaceæ, comprising only seven or eight species, but serving to illustrate how a family once widely distributed may later occur only in widely separated areas. One genus, *Stemona*, occurs from the Himalayas to southern Australia; another, *Crotonia*, in Florida, Georgia, and Japan; and the third, *Stichneuron*, in the East Indies.

Dicotyledons. There are approximately 80,000 species of dicotyledons, about equally divided between the two great groups Archichlamydeæ and Sympetalæ. These must be considered separately, since they have developed independently and are quite distinct in the general features of the geographical distribution.

Archichlamydeæ. The most conspicuous facts in connection with the distribution of the Archichlamydeæ are as follows: In the representation of tropical families there is a notable pairing of continents, the American tropics usually being one member of the pair, and Asia or Africa the other. For example, the great

alliance to which buttercups, mustards, poppies, laurels, etc., belong is represented by tropical forms chiefly in America and Asia, the omission of Africa being notable; the alliance to which geraniums, balsams, flaxes, rue, etc., belong has its tropical forms chiefly in America and Africa; while the melastomas are massed in Brazil, and the myrtles are common to South America and Australia. Thus the predominance of America appears in the display of tropical Archichlamydeæ. This becomes all the more clear from the statement that in America almost all the tropical and subtropical families are represented, and two very large families, the cactus and melastoma families, are found as natives exclusively in America. The Archichlamydeæ are also peculiar in not containing any terrestrial family of worldwide distribution, as do the monocotyledons and Sympetalæ; nor is there any distinctly boreal family as among the Sympetalæ. There have been developed among them certain very characteristic north-temperate families, the smartweeds, pinks, crowfoots, mustards, saxifrages, roses, evening primroses, and umbellifers, all of which, however have their representatives in tropical and boreal regions; but the display of these forms is not to be compared with the massing of the Sympetalæ in the temperate regions. While there is a much larger display of Archichlamydeæ in the north-temperate than in the south-temperate regions, two very large and characteristic families have been developed in the Southern Hemisphere, viz., the Proteaceæ, trees that belong to the same general alliance as do the oaks, elms, hickories, etc., of the Northern Hemisphere; and the Thymelæaceæ, characteristic of Australia and the Cape region of Africa, and represented in our American flora by the leatherwood (*Dirca*). The Archichlamydeæ contain most of the hardwood trees, and it is interesting to note that the trees of the tropics and the temperate zones belong to different alliances. For example, the oaks, hickories, elms, beeches, birches, etc., belong to a great alliance characteristic of north-temperate regions, while the laurel, belonging to an entirely different alliance, is the characteristic forest type of the tropics. By far the greatest family of the Archichlamydeæ, in point of numbers and general success, is the pea family (Leguminosæ), represented by about 7000 species. Although it seems to be abundantly displayed in the temperate regions, it is far more extensively represented in the tropics, being the greatest tropical family of the group. The lianas or climbers are chiefly represented among Archichlamydeæ by such forms as the grapevines and their allies. Naturally, they are chiefly displayed in tropical forests and are most largely developed in the moist forests of South America, as are the epiphytic orchids and bromeliads among the monocotyledons. Their next largest display is in Africa.

Sympetalæ. The Sympetalæ are the ranking plants of the plant kingdom and are also those most recently evolved. While they include a number of shrubs and trees in the tropics, they are by no means so extensively represented in temperate regions by shrubs and trees as are the Archichlamydeæ. The prominent facts of their distribution are as follows: The earlier groups of angiosperms (Archichlamydeæ and monocotyledons) were massed in the tropics, the temperate and boreal regions being rela-

tively poor in true flowering plants. The Sympetalæ, therefore, while largely represented in the tropics, found the temperate and boreal regions comparatively free for occupation, and it is in these regions that they have become peculiarly dominant. This does not mean that there are not more Sympetalæ in the tropics than in the temperate regions, for the proportion of species in favor of the former is about three to two; but it does mean that this is about the normal ratio of tropical increase, which is far exceeded by the other groups. Accordingly, of the Sympetalæ alone can it be said that their distribution throughout tropical and temperate regions is about uniform. The families of Sympetalæ are not only better defined structurally than those of the Archichlamydæ, but their geographical distribution is much more definite. This follows the fact that they are more highly specialized and more definitely related to environment than are the Archichlamydæ. Among the Sympetalæ, three families—the plantains, mints, and composites—have a world-wide distribution. The Compositæ, as the ranking family of the plant kingdom, and also the youngest and largest, deserves special mention. It includes at least 12,000 species, which, although found everywhere, are most numerous in the temperate regions, where they constitute from one-tenth to one-seventh of all of the seed-bearing plants of every flora. They are especially characteristic of temperate America, where asters, goldenrods, sunflowers, etc., abound. Two great north-temperate families, the figworts and the borages, have also been developed; and the heaths form a family characteristic of boreal conditions.

The impress a peculiar region may have upon the general aspect of its vegetation, resulting in the assumption of the same general appearance by plants of the most diverse relationships, is illustrated by the fact that many sympetalous families of South America are characterized by a heathlike habit, the region being known as one of the heathlike plants. There is no such notable continental pairing as is shown by the Archichlamydæ and the monocotyledons, due probably to the fact that extensive forests and boreal distribution permit free intermingling of continental flora. Among tropical Sympetalæ, however, the pairing is somewhat evident, and in tropical display America is distinctly dominant. It is also worthy of note that there is a remarkable paucity of aquatic plants among Sympetalæ compared with Archichlamydæ and monocotyledons. This seems to be related to the fact that the latter groups had already become well established in fresh and brackish waters, while it was the temperate and boreal land surface that was especially free for occupation by the Sympetalæ.

Conclusion. Through the lapse of time since the advent of plant life upon the earth, the meteorological factors—wind, moisture, heat, and light—have been at work as plant distributors. At divers times and in many parts of the world their work has been interrupted, assisted, or rendered nugatory by geological agents—glaciers, especially of the ice age, which have driven vegetation before them and exiled many plants from their pristine homes; seismic upheavals or sinkings, the former interposing tall mountain ranges, the latter wide oceans, beyond which certain species could not migrate,

and which to a greater or less degree isolated these species, sometimes genera, families, and even tribes. The efforts of these factors and agents have been and are assisted by man, by other animals, and by plants; the first either wittingly carrying useful or ornamental species from country to country, or more often unwittingly introducing useless or even noxious ones; the second in a more limited range transporting seed either in or on their bodies; the third breaking down and disintegrating rock, becoming incorporated with the detritus and thus affording a habitation to a succeeding plant society. Far from having ceased their labors, these meteorological factors and geological agents, working in conjunction or in conflict, still profoundly influence the ceaseless change in the distribution of plants.

DISTRIBUTIVE LAW. In its elementary form this mathematical law may be expressed thus: To multiply any compound expression by a simple expression is to multiply each term of the compound expression by the multiplier and to write the separate products in order, affecting each product with its proper sign. Symbolically:

$$a(b + c + d \dots) = ab + ac + ad \dots$$
 a, b, c, \dots being any algebraic quantities. See CALCULUS.

DISTRIBUTOR (in motor vehicle). See MOTOR VEHICLE.

DISTRICT (ML. *districtus*, territory wherein a lord may distrain, from Lat. *distringere*, to pull asunder). A political subdivision of a city, county, or state, which forms the basis of legislative representation. Its boundaries are fixed by law, either by the enactment of the legislature or by the adjudication of a court to whom this power is delegated. The citizens thereof assemble within these boundaries and vote for local, state, and national officials. In the United States the boundaries of the congressional district in each State are determined by the State Legislature after the apportion-

ment of representation has been made by Congress, following on every decennial census. The ratio of representation under the census of 1910 was 212,407, and the total number of congressional districts 435. There is no definite principle laid down for the manner in which a State may be redistricted, and, as a rule, the party in power will, as far as possible, so distribute representation as to insure its continued supremacy. See GERRYMANDER.

For the purposes of taxation the term has a broader meaning, and the Supreme Court of the United States has decided that for the collection of taxes a district means any part of a State described for the purpose of assessment, without reference to the civil or political divisions of the State made for election purposes. See *Kelly v. Sanders*, 99 *United States Reports*, p. 441.

DISTRICT ATTORNEY. In the United States, the public prosecuting officer within a defined district. The office is one of great importance in the administration of the criminal law, including, as it does, the investigation of charges of crime, the gathering of evidence against alleged criminals, the submission of criminal charges to the grand jury of the county or district, and the drawing of indictments, as well as the supervision of the several stages of the criminal prosecution and the actual trial of the accused. The power necessarily inherent in the office of the district attorney to determine whether the evidence in a given case warrants the finding of an indictment and under certain circumstances to dismiss an indictment or to enter a *nolle prosequi* (q.v.), gives him a position of commanding influence in criminal prosecutions. In some States and in the Federal courts the district attorney can dismiss or nol-pros an indictment only with the consent of the court. As the jurisdiction over crimes is, under the Federal system of the United States, divided between the Federal and the State courts, the Federal government has one set of district attorneys, and each State has an entirely different set for the same territory. The former are appointed by the President and are in reality deputies of the Attorney-General of the United States, to whom they are required to make report of their official acts, and to whose direction and control they are subject. They are appointed for the several districts into which the United States are divided for district courts, and are charged with prosecuting offenses against the Federal government as well as with conducting civil actions on behalf of the government and in some cases on behalf of government officers.

In most of the States a State district attorney is elected in each county, although his most important duties, as a rule, are discharged in prosecuting criminals before the State courts. He is also the prosecuting officer before the county court of the county in which he is elected. He is in some States subject to the control of the Attorney-General and in New York is removable by the Governor. In certain contingencies he may call upon the Attorney-General of the State for assistance in important criminal prosecutions. His duties and powers are regulated by the statutes in accordance with which he is appointed or elected. Under the common-law system the prosecution of criminal offenses was left to the initiative of the persons injured or

other private persons representing them, and in England it was not until 1879 that the state undertook that duty in any effective or systematic way. By Act of Parliament in that year (42 and 43 Vict., c. 22) and in 1882 (47 and 48 Vict., c. 58) a new department was created under a "Director of Public Prosecutions," whose functions and powers are substantially like those of the district attorney in the United States. See CRIME; CRIMINAL PROCEDURE.

DISTRICT COURT. A court having a jurisdiction limited to a defined judicial district. Several of the United States have divided their territory into judicial districts, but the court of the district is usually a branch or "term" of the highest court of original jurisdiction of the State and not a separate tribunal.

The District Courts of the United States, however, are district tribunals subordinate to the circuit courts of appeal. With the exception of cases affecting diplomatic representatives of foreign powers and those in which a State is a party, as to which the Supreme Court has original jurisdiction, the district courts have original jurisdiction in all cases to which the judicial power of the United States extends. Prior to 1911 the circuit courts shared original jurisdiction with the district courts, but by the Judiciary Code, enacted by Congress in that year, the circuit courts became purely appellate tribunals, their original jurisdiction being transferred to the district courts. Criminal bankruptcy and admiralty causes are important branches of their jurisdiction. Each of the nine judicial circuits (corresponding to the number of justices of the Supreme Court) is divided into a larger or smaller number of districts. In some instances a district embraces the whole territory of a State; in others, States are divided into two or more districts. In three instances a single judge serves two districts. In the southern district of New York and in the district of Alaska there are four judges; and 13 districts, one of which is the district of Texas, have two judges each. With these exceptions there is one judge for each district, making a total of 84 district judges in all. See COURT, *United States Courts*.

DISTRICT OF COLUMBIA. A territory embracing 60 square miles of land surface and 10 square miles of water surface situated on the east bank of the Potomac River, between Maryland and Virginia (Map: Maryland, K 5 and B 7). The surface is flat and marshy along the Potomac, but elsewhere gently rolling and hilly. The Anacostia River, or Eastern Branch (of the Potomac), crosses the southern portion, and Rock Creek, a stream of considerable picturesque scenery, traverses the northern part. The climate (mean temperature, 55° F.) is subject to sudden and extreme variations of temperature. The rainfall is about 50 inches annually. Snow falls in the winter, but is generally of short duration. The soil is a light sandy loam. In 1910 about 6000 acres, 13 per cent of the area, was contained in farms. The nature of the agricultural industries is determined by the proximity to Washington, and the products are chiefly those of the vegetable garden and the dairy. The largest acreage therefore consists of hay and pasture lands and gardens. Floriculture is of considerable importance, the annual returns from this source exceeding half a million dollars.

Manufactures. Although the city of Wash-

ington, which is coextensive with the District of Columbia, is not essentially a manufacturing city, the number and importance of its industries are steadily increasing. Manufacturing operations carried on in the District by the Federal government are of considerable importance, but, as they are conducted under conditions which in many respects differ from those prevailing in establishments operated under private ownership, statistics for them are not included with those of the older industries. The table below shows the principal industries in 1909 and the most important facts in relation to them.

miles; in 1850 the population was 51,687; in 1860, 75,080; in 1870, 131,700; in 1890, 230,392; in 1900, 278,700; in 1910, 331,069; in 1913 (police census), 353,297. There was in 1913 a very small foreign-born population, but the negro element was large—98,144. The mass of the population is centred in the city of Washington. The villages surrounding it bear the relation of suburbs to the city proper.

Government. The District of Columbia was established as the seat of government of the United States under authority of Acts of Congress approved by President Washington July

INDUSTRY	Number of establishments	WAGE EARNERS		VALUE OF PRODUCTS		VALUE ADDED BY MANUFACTURE		PER CENT OF INCREASE	
		Average number	Per cent distribution	Amount	Per cent distribution	Amount	Per cent distribution	Value of products 1904-09	Value added by manufacture 1904-09

All other industries.....	231	3,798	49.3	12,156,000	48.1	7,033,000	46.8

A minus sign (—) denotes decrease. Where the percentages are omitted comparable figures can not be given.

It will be noted from this table that, exclusive of the establishments operated by the Government, there were in 1909 in the District 518 manufacturing concerns, which gave employment to an average of 9758 persons and paid out \$6,835,000 in salaries and wages. In general, the industries of the District show a much greater increase from the period 1904-09 than for the period 1899-1904. The average number of wage earners employed in 1909 was 7707, of whom 6861 were males and 827 females (of 16 years of age or over). Those in employment under 16 years of age numbered 19, compared with 74 in 1904. A large proportion of the wage earners of the District are employed by the Federal government in operations similar to those carried on in manufacturing establishments under private ownership. These operations, however, are carried on for the exclusive benefit of the government, and, as the products are not manufactured for sale and therefore have no commercial value, no value of products can be shown. Of these industries the most important are those connected with engraving and printing, including the Bureau of Engraving and Printing, and establishments operated in the Geodetic Survey, the Geological Survey, and the Department of State; those connected with the manufacture of professional and scientific instruments, chiefly for the Smithsonian Institution, and those connected with the government printing, which includes the Government Printing Office and establishments operated in the Weather Bureau and the War Department. The total number of persons engaged in these and other industries in 1909 was 11,666. The wage earners numbered 10,657. The capital invested was \$28,479,599.

Population. The population in 1800, when the area was nearly one-third larger than at present, numbered 14,093; in 1846 the area was reduced from 100 square miles to 69¼ square

16, 1790, and March 3, 1791. It originally consisted of 69¼ square miles ceded by Maryland and 30¼ square miles ceded by Virginia. When the District was first created, the only municipal corporation it contained was the town of Georgetown, which was governed by a mayor and city council. The remainder of the District was under the jurisdiction of a body of justices of the peace, styled "Justices of the Levy Court." The portion of this remainder which was laid out as the city of Washington by the commissioners appointed by the President of the United States under the Act of July 16, 1790, and the amendment thereto, was governed by these commissioners and the President of the United States, from Jan. 22, 1791, until the incorporation of the city council. This form of control continued until June 1, 1871, when these three governments were abolished and the whole District of Columbia was placed under a territorial form of government, entitled "The District of Columbia," which consisted of a governor; a board of public works; a secretary; a board of health; a council of 11 members, all appointed by the President of the United States; a house of delegates, consisting of 22 members, and a delegate in the House of Representatives of the United States, both elected by the people of the District. This form of government was abolished by Congress on June 20, 1874, and a temporary government, consisting of three commissioners appointed by the President of the United States, was appointed in its place. This continued until July 1, 1878, when, by an Act of Congress approved June 11, 1878, it was succeeded by the present permanent form of municipal government, entitled "The District of Columbia," the principal executive power of which is vested in a board of three commissioners, appointed by the President of the United States.

On Sept. 7, 1846, the portion of the District derived from Virginia was ceded to that State upon the petition of the inhabitants thereof, by a vote of 763 to 222.

The people of the District of Columbia have no vote in municipal or national affairs.

History. Within the present District, probably on the site of Anacostia, stood the famous Indian village of Powhattan, Nacochtank, or Anacostan, which Captain Smith visited in 1608. In 1663 Francis Pope, an Englishman, established a plantation where Washington was afterward built. To the site of Georgetown settlers came probably as early as 1665, and in 1751 a town was laid out here, which in 1789 was regularly incorporated. Immediately after the close of the Revolution there was much discussion about the location of the permanent seat of government, and, after the adoption of the Constitution in 1789, this question gave rise to the first debate which aroused bitter sectional feeling. Finally, by an Act approved July 16, 1790, and amended March 3, 1791, after the claims of New York, Philadelphia, Germantown, Baltimore, Wilmington, Del., and several other places had been fully considered, Congress decided that after 1800 the Federal capital should be moved to "a district or territory not exceeding 10 miles square on the River Potomac between the mouth of the Eastern Branch and the Conogocheague." This decision was reached partly as the result of a compromise and partly in deference to the known wishes of Washington.

DISTRINGAS, *dis-trīng'ās*. A writ or process in the nature of an attachment or execution, taken from the emphatic word of the writ directed to the sheriff, viz., "It is hereby commanded *that you distrain*" the defendant, etc. It was formerly issued in England for a variety of purposes, such as forcing a defendant who neglected to appear to present himself in court, or forcing a corporation to obey a subpoena, or compelling jurors to attend court, or a defendant in an action in detinue after judgment to deliver the goods to the plaintiff. The writ has been abolished in England, as well as in most of the United States, although in Virginia it is retained as a form of execution in cases of detinue. See **EXECUTION**.

DISTURBANCE. The common-law offense of violating an incorporeal property right, as an easement, a profit, or a public right, as a highway, in the land of another. As such rights do not carry with them the right of possession, they cannot usually be protected by the action of trespass, which contemplates an interference with the possession of a corporeal interest in land. But such rights, however impalpable, do really constitute property, and they will be protected by appropriate legal proceedings against a disturbance by the owner of the land or by any other person whatsoever. In a few cases, as where one has an exclusive right to the use of another's land, as a sole and several pasturage—such right being nearly equivalent to the right of possession of the premises—the action of trespass is available for its protection. In other cases the disturbance constitutes a nuisance, which may be abated either by its abatement by the act of the party injured, thereby, or by the action known as "trespass on the case," or, more shortly, "case"; or, in a proper case, by an injunction in equity.

The forms of disturbance are various, depending upon the nature of the right involved. Thus,

a common of pasture may be disturbed by shutting or driving out the cattle of the claimant of the right, or by unlawfully permitting other cattle to crop the herbage. In the last case the claimant may take the cattle damage feasant and impound them. A franchise is disturbed by wrongfully taking the tolls accruing therefrom or by setting up a competing use, as a bridge, ferry, or turnpike. Disturbance of ways happens "where a person who hath a right of way over another's ground by grant or prescription is obstructed by inclosures or other obstacles, or by plowing across it, by which means he cannot enjoy his right of way, or at least in so commodious a manner as he might have done" (2 Bl. Com. 242). This is remedied by the act of the party injured, removing the obstacle, or by an action on the case.

All of these forms of disturbance of private rights, together with the remedies appropriate to them, exist to-day, as at common law, without material alteration. The ancient wrong of *disturbance of tenure*, which consisted in breaking the feudal tie of lord and tenant, has become obsolete with the disappearance of the feudal system of land tenure. The disturbance of public rights, as of a highway or a public right of common or of fishing, may be either a private nuisance, remediable by the individual whose right is interfered with, or a public nuisance, or purpresture, remediable by the state. See **EASEMENT**; **NUISANCE**; **PROFIT**; **TRESPASS**; **ETC.**; and consult the authorities referred to under **EASEMENT**.

DISTURBANCE OF PUBLIC WORSHIP.

A modern statutory offense, which has in the United States generally superseded the common-law offense of brawling (q.v.) in church. As generally defined, it consists in any willful interference, by acts or words, with the good order of persons assembled for religious worship, whether within a consecrated place of worship or elsewhere. The offense may be committed by a person present in the place of worship or by noisy conduct on the outside, and to constitute such acts or conduct a disturbance it is not necessary that the congregation assembled shall at the time be engaged in worship. It is sufficient if they are assembled for that purpose. The offense constitutes a misdemeanor, punishable by fine or imprisonment. It is not such a violation of private rights as to furnish grounds for an action for damages, unless it be habitual or so persistent as to amount to a nuisance. In that case the remedy by action lies in the hands of the trustees or other officers in whom the possession of the place of worship is vested. See **NUISANCE**.

DIS'TYLE (from Gk. *duō*, *duō*, two + *στῦλος*, *stylos*, column). In classic architecture, a composition showing two columns in front. When these stand between antæ or the ends of projecting side walls, the building is called *distyle in antis*.

DISUSE. One of the negative, but yet important, factors of evolution is disuse. Its significance was first pointed out by Lamarck in his first law of evolution, wherein he says that the constant lack of use of an organ "imperceptibly weakens it, causes it to become reduced, progressively diminishes its faculties, and ends in its disappearance." An example he gives of the reduction and loss of organs or limbs is that of snakes, which by change of habit from originally running to gliding directly along the

... we acquired greater length of body, legs, being thus disadvantageous to them, have disappeared by atrophy.

He also instances the loss by disuse of teeth in the baleen whales and in birds, and in the anteater, "whose habit of not masticating its food has been for a long time established and preserved in its race." He calls attention to the small reduced forelegs of the kangaroo, which "have remained thin, very small, and weak," and especially to the whale, saying: "Indeed, since the enormous length of time during which these animals have lived in the depths of the sea, never using their hind feet in seizing objects, their disused feet have wholly disappeared, as also their skeleton, and even the pelvis serving as their attachment."

Lamarck taught that the effects of disuse are inherited—a doctrine maintained by Darwin, who remarks: "I think there can be no doubt that use in our domestic animals strengthens and enlarges certain parts, and disuse diminishes them; and that such modifications are inherited," adding that in free nature "many animals have structures which can be explained by the effects of disuse." See USE; INHERITANCE.

Darwin also calls attention to the absence in many male dung beetles, including the *ateuchus* or "sacred" beetle of the Egyptians, of the anterior tarsi or feet, and this atrophy he thinks it safe to regard "as due to the effects of long-continued disuse." The same may be said of the reduction and loss of the fore tarsi of butterflies of the family *Nymphalidæ*. For cases of the loss of eyesight, of eyes, and the optic nerves and lobes in animals living in darkness, see CAVE ANIMALS.

Cases of the modification of animals by disuse occur in nearly every group. Among the mollusks it is noticeable in those bivalves, such as *Mytilus*, *Cardium*, etc., which live attached to other bodies. The oyster was originally equivale and capable of freely moving, but by disuse, owing to change in its ancestors to a fixed mode of life, it has lost its siphons, its foot, and the shells are of unequal size. It is so with the fresh-water mussel (*Mytilaria*) of South America, which has acquired sedentary habits. It is the case in a still more marked way with the barnacles. Among insects there are countless instances of the reduction and partial or total loss of limbs in woodborers, in the grubs of many beetles living in seeds, nuts, etc.; in the larvæ of gallflies, of ants, wasps, bees, and in the larvæ of the ichneumon flies. If, as is very clearly the case with insects, we also attempt to explain the loss of limbs in the two-legged *Bipes*, *Chiroteles*, or the entirely legless *Amphisbæna* and the glass snake (*Ophiosaurus*), we shall see that it is evidently due to disuse and its inherited effects. Reasoning from this to the origin of the order of snakes, it becomes apparent that they have diverged from the lizards, and that Lamarck was right when he attributed their origin to such a cause. (See DEGENERATION.) The majority of snakes possess no trace of vestigial legs, the exception being the boas, in which there are two minute hornlike projections from under the scales and the hinder pair of limbs. Disuse has also made its mark in the running birds, the emu, ostrich, and cassowary, where the wings have by disuse retrograded, and as a compensation the legs and particularly the toes have become adapted for a cursorial mode

of locomotion. Other examples of disuse are the loss of the thumb in the thumbless ring monkey (*Colobus*) of Africa, and the spider monkey (*Ateles*) of Central and South America.

It is to be observed in these cases of the reduction and loss of digits that it is generally complete and thoroughgoing; there are no vestiges left as seen in the two-toed ostrich and the three-toed moa, apteryx, emu, and cassowary. The reduction is complete and is probably due to the high antiquity of these birds. That this is the case is suggested by the presence of the two splint bones of the horse, while the bones of the two other toes which began to be lost at an earlier geological age have entirely lapsed. In the potto (*Perodicticus*), a lemur which has partly lost the index finger, there is a distinct vestige left, the reduction having apparently taken place late in the phylogeny of this form.

In the case of the loss of wings in insects, of which there are so many cases, we have all grades of reduction. Some are completely apterous, with no vestiges of wings; in others there are little flaps left. The absence of wings in all these cases is clearly the result of change in the surroundings, or mode of life, as the wingless beetles, etc., which live under stones, or burrow in the ground.

A very interesting question here arises: Could these losses ever be restored? When we consider forms like the stick insect, whose ancestors of the Carboniferous period had large, well-developed wings; or the flea, and the braula, the sheep tick (*Melophagus*), and the bat tick (*Nycteribia*), it seems impossible that they could be restored to their ancestral winged form, even if the attempt were made to do so artificially in a laboratory of experimental evolution. Other cases are the loss outright of the collar bone in running mammals like the horse and most carnivora, of the canines in rodents, and all the teeth in the anteaters. It may be considered as contrary to the course of nature to suppose that these structures, once lost, and lost, could ever be restored. See DEGENERATION.

Here arises a question: Are there examples of the replacement by entirely new structures of organs lapsed by disuse?

The clearest case is that of the duckbill of Australia. Poulton has shown that the embryo duckbill has for a brief season the rudiments of three teeth in each upper maxilla, but that these are very soon lost, while their place is occupied by the posterior set of the eight horny plates situated in the upper and lower jaws, two upon each side of each jaw. The calcified true teeth of *Ornithorhynchus* became, Poulton thinks, unsuited to the needs of the animal when it adopted a mode of life in which large quantities of sand were necessarily taken into the mouth with the food, when it first fed upon insect larvæ, etc., which it dug with its broad bill out of the mud and sand at the bottom of streams. "Under such circumstances two things might happen: the true teeth might be protected from the effects of wear by continuous growth from persistent pulps or by a continued succession; or a constantly growing horny plate might be developed from the oral epithelium and might be substituted for the true teeth." See DUCKBILL, and illustration of teeth thereunder.

A less satisfactory example is that of the replacement of the horny teeth of the tadpole by the teeth of the frog or toad. But Nature as a rule gets her new organs by a more economical

and rapid method, i.e., by change of function of the same organ, which, owing to a change of habit, loses its original use and becomes modified to carry on entirely different functions. See FUNCTION CHANGES.

DISVEL'OPED, or **DEVEL'OPED** (from OF. *desveloper*, to unfold). In heraldry, a term applied to the colors of a regiment or noble house, when flying.

DITCH (ME. *diche*, AS. *dīc*, dike, Icel. *dík*, MHG. *tich*, ditch, Ger. *Teich*, pool; connected ultimately with Gk. *τείχος*, *teichos*, wall). 1. In agriculture, a trench made along the sides of fields, or following the contour of the land, to collect and remove the excess of water. In ordinary farm operations ditches are largely constructed by hand, but efficient ditching machines are found in the market. In modern practice open ditches have been largely superseded by underground tile drains, thus effecting a great saving of land and securing better drainage. In irrigated regions an open ditch is often used to convey the water from the main canals to the "laterals" which distribute it over the field. See DRAINAGE; IRRIGATION.

2. Part of the defense works of a fortified place (also called foss or moat). See FORTIFICATION; REDOUBT.

DITHMARSCHEN, dīt'mārsch-en, NORTH AND SOUTH (*Norder* and *Süder Dithmarschen*). The name given to the western portion of Holstein, Prussia, lying along the coast of the North Sea between the Eider and Elbe rivers. It has an area of about 500 square miles, lies very low, and is for the most part marshy, but with some good pasture land, from which the sea is kept by dikes. It was originally inhabited by Saxons and Frisians, who were subjugated and Christianized by Charlemagne in 804. In 1182 they regained independence, and in the latter part of the Middle Ages and at the time of the Reformation Dithmarschen formed a peasant republic, with a well-developed system of local autonomy. The inhabitants distinguished themselves by their bravery in defending their liberty against their neighbors. In 1559 they succumbed to the arms of Holstein and Denmark. In 1866 Dithmarschen, along with the rest of Holstein, was incorporated in Prussia. North and South Dithmarschen each still forms an independent district in the Prussian Province of Holstein. Pop., 1900, 86,019; 1910, 96,373. Consult: Dahlmann's edition of Neecorus, *Chronik der Dithmarschen* (Kiel, 1827); Volkmar, *Geschichte des Landes Dithmarschen* (Brunswick, 1851); Nitzsch, *Das alte Dithmarschen* (Kiel, 1862); Nehlsen, *Dithmarscher Geschichte* (Hamburg, 1894).

DITH'YRAMB. See DITHYRAMBUS.

DITH'YRAM'BUS (Lat., from Gk. *διδύραμπος*, *dithyrambos*, of uncertain etymology). An orgiastic hymn sung in honor of the god Dionysus, accompanied by music on the flute and a dance around the altar. The subject was originally the birth and life of Dionysus, but later other themes too were employed. Its development into artistic form took place at Corinth—according to another tradition at Naxos—and was attributed by the ancients to the mythical Arion. From the sixth century till about 300 B.C. the hymn was sung by a chorus of 50, generally dressed as satyrs, the companions of Dionysus. At Athens there were annual contests at the Greater Dionysia, Lesser Dionysia, Panathenæa, Thargelia, and Lenæa (see GREEK FESTIVALS),

between dithyrambic choruses entered by the 10 tribes. The prize in the earliest period was an ox, in the fifth century and later a tripod. Out of the dithyramb arose the choral portion of Greek tragedy. After the development of tragedy the dithyramb was still composed independently, e.g., by Philoxenus, Bacchylides, and Pindar. Of the hymns of the dithyrambic writers only fragments are preserved. Consult Smyth, *Greek Melic Poets* (London, 1900), and Schmidt, *Zur Geschichte des griechischen Dithyrambus* (1901).

DITMARS, RAYMOND LEE (1876—). An American naturalist, born in Newark, N. J., and educated at the Barnard Military Academy, New York City, where he graduated in 1891. He then served as assistant curator of entomology at the American Museum of Natural History, in New York, for five years, as a reporter for the *New York Times* from 1897 to 1898, and thereafter as curator of reptiles at the New York Zoölogical Park; in 1902 he was also appointed curator of mammals. He made an especially careful study of reptiles and published the valuable *Reptile Book* (1907) and also *Reptiles of the World* (1910).

DIT'TANY (OF. *dittain*, *dictame*, Lat. *dictamnium*, Gk. *δίκταμνον*, *diktamnon*, dittany, from Gk. *Δίκρη*, *Diktē*, a mountain in Crete, where the plant grew in abundance), *Dictamnus*. A genus of plants of the family Rutaceæ. The common dittany, also called bastard dittany or fraxinella (*Dictamnus albus*), a native of sunny mountains and rocks and dry mountain forests of the south of Europe, especially in calcareous soils, is cultivated as a garden flower. It is a perennial, with stem 1½ to 3 feet high, unbranched, bearing a few pinnated leaves, and terminating in a beautiful erect raceme of 10 to 20 flowers of a fine rose color, with darker veins, more rarely white. When in flower, the plant diffuses a powerful fragrance from its numerous oil glands, and during dry, hot weather exhales a quantity of volatile oil the sudden combustion of which makes a slight flash when ignited by a candle. The root is thick, white, and very bitter, and was formerly in high repute in medicine as a tonic stimulant. Dittany of Crete (*Origanum dictamnus*), used as a febrifuge, and the dittany of the United States (*Cunila origanoides*), are very different plants, belonging to the family Labiatae. The latter is found upon dry hillsides from New York to Georgia and westward to Arkansas. The plant has smooth, heart-shaped leaves, and clusters of small white or purplish flowers.

DITTENBERGER, dīt'ten-bērk-ēr, WILHELM (1840—). A German classical scholar, born at Heidelberg. He studied at Jena and Göttingen and in 1874 was appointed professor of classical philology at the University of Halle. His publications include: *De Ephebi Attici* (1863); *Inscriptiones Atticæ Ætatis Romanæ* (1878-82; vol. iii of the original edition of the *Corpus Inscriptionum Atticarum*, published by the Berlin Academy); *Sylloge Inscriptionum Græcarum* (1883; 2d ed., 3 vols., 1898-1901); *Corpus Inscriptionum Græcarum Græciæ Septentrionalis* (1892); *Orientis Græci Inscriptiones Selectæ* (2 vols., Leipzig, 1903-05). Consult Larfeld, *Griechische Epigraphik* (Munich, 1914).

DITTERS, dīt'tērs (DITTERS VON DITTERSDORF), KARL (1739-99). An Austrian violinist and composer. He was born in Vienna and

studied under König, Ziegler, Trani, and Bono. Much of his education was due to the interest in him of Prince Joseph of Hildburghausen, whose orchestra Ditters afterward led. He was a brilliant violinist and won wide success, the tour with Gluck (1761) establishing him firmly as a violin virtuoso. He was a prolific composer in almost every department of composition, but, excepting his charming comic opera *Doktor und Apotheker* (1786), nothing of his work remains in use. He had the misfortune to have his undoubted gifts overshadowed by the brilliant genius of Mozart. His music is marked by correctness of style, fluency of expression, and beauty of melody. Few musicians of his day met with greater appreciation, had more honors conferred upon them, or held more honorable positions. He died at Castle Rothlhotta, near Neuhaus, in Bohemia. The best edition of his autobiography is that edited by Spazier (Leipzig, 1801), reprinted by E. Istel (Leipzig, 1909).

DITTON, HUMPHREY (1675–1715). An eminent English mathematician. He was for some years a dissenting clergyman, but through the influence of Sir Isaac Newton obtained a professorship in the new mathematical school at Christ's Hospital, where he remained through life. He and Whiston devised a new method for determining longitude at sea, but it was rejected by the Board of Admiralty. Ditton's death has been attributed to his disappointment. He was the author of mathematical works, including: *General Laws of Nature and Motion* (1705); *An Institution of Fluxions* (1706; 2d ed., 1726); *Treatise on Perspective* (1712); *Discourse on the Resurrection of Jesus Christ* (1714).

DIU, dē-ō' (Gujarati, from Skt. *dvīpa*, island, so called from the situation of the town). A seaport, situated at the eastern extremity of an island of the same name, separated from the peninsula of Kathiawar, Bombay Presidency, India, by a narrow strait (Map: India, B 4). Formerly a prosperous city of more than 50,000, it has lost its commerce because its harbor is growing shallower. It is fortified and has a tolerably safe harbor, with a general depth of 3 or 4 fathoms. The chief occupation is The place has been in possession of since 1535. The area of the island is about 20 square miles. Pop., 1900, 14,614.

DIURETICS (Lat. *diureticus*, from Gk. διουρητικός, *diourētikos*, promoting urine, from διουρεῖν, *diourein*, to urinate, from διά, *dia*, through + οὔρεν, *ourein*, to urinate, from οὔρον, *ouron*, urine). Medicines having the property of increasing the secretion of urine. They are of several classes: 1. *Vascular or cardiac diuretics*, which act by increasing arterial tension or the blood supply of the kidneys. These include all cardiac stimulants, important representatives being digitalis, caffeine, theobromine, diuretin, convallaria, scoparius, sparteine, apocynin, squill, and strophanthus. 2. *Refrigerant diuretics* include the salts of sodium and potassium, particularly the acetate, citrate, and bitartrate of potassium. 3. *Stimulant diuretics* are those which have a direct stimulating action upon the genitourinary tract; such as juniper, turpentine, copaiba, cubebs, oil of sandalwood, buchu, and cantharides. Some of these are extremely irritating and must be used very cautiously. 4. *Water* is a most important diuretic, increasing the amount of fluid in the blood.

Diuretics are used in conditions in which the quantity of urine is diminished; to aid the absorption of fluid in dropsy or collections of fluid in the body cavities, whether the result of inflammation, such as pleurisy, or of imperfect action of the heart, kidneys, etc.; to aid in the elimination of poisons; and to dilute the urine so as to make it less irritating in inflammations of the genitourinary tract, or to prevent the formation of calculi, or stones, in the kidneys or bladder. Many of the diuretics mentioned are described in separate articles. Some diaphoretics, such as pilocarpine, at times act as diuretics. The action of this class of medicines is very uncertain, depending largely upon the individual, and varying in the same person under different conditions.

DIURETIN (from Gk. διουρεῖν, *diourein*, to urinate), or SODIO-SALICYLATE OF THEOBROMINE, $C_7H_7NaN_3O_2 + NaC_7H_5O_3$. A valuable diuretic, especially in cases of dropsy of cardiac origin; but, like all drugs of its class, very uncertain in its action on the heart and kidneys; to aid in stimulating the cells of the kidney. It occurs as a white powder which is freely soluble in warm water and remains dissolved after cooling. See SALICYLIC ACID.

DIURNAL MOTION (Lat. *diurnalis*, daily, from *diurnus*, daily, from *dies*, day). The apparent daily motion of a heavenly body caused by the rotation of the earth on its axis. See AXIS; EARTH; PLANETS.

DIV. See DEV.

DIVAN, di-vān'. A Persian word having various significations, being used in the sense of a muster roll, a register of payments or accounts, or a place for the preservation of a register; and it is also applied to a collection of poems or songs by one and the same author. Goethe uses it in this sense in his *Westöstliche Divan*. Divan means next an administrative board; the council of state at Constantinople is *humayun* ('most illustrious divan'). Finally, divan is the name for the state or reception room in Oriental palaces. Along the walls of the room are ranged low couches, covered with rich carpets and provided with cushions. Hence the name "divan" is used for a kind of couch or sofa.

DIVER, div'ər. The name of several water-birds, especially loons and grebes, remarkable for quick diving—in some cases so quick as to dive at the flash of a gun and escape the shot. The whole order (Pygopodes) to which these birds belong is often spoken of as "divers." See LOON.

DIVER, THE. A poem by Schiller (q.v.).

DIVERS, di'vərz, EDWARD (1837–1912). An English chemist and educator, born in London, and educated at the Royal College of Chemistry and at Queen's College, Galway, Ireland. In 1870 he lectured on medical jurisprudence at the Middlesex Hospital Medical School; and he served as professor of chemistry at the Imperial College of Engineering in Japan from 1873 to 1882, when he was chosen principal of that institution. He was vice president of the Chemical Society (1902) and president of the chemical section of the British Association and of the Society of Chemical Industry (1905). He is author of several chemical researches.

DIVER'S PALSY. See CAISSON DISEASE.

DIVERTIMENTO, It. pron. dē-vār'tē-mān'tō (It., diversion). 1. A term originally applied to the dances interpolated between the scenes

of the older French opera (*Divertissement*). 2. A composition somewhat like the modern suite (q.v.). It consists generally of five or six movements in free style, but the music is always of a simple character. 3. An entr'acte in an opera. 4. An episode in a fugue.

DIVES, *dī'vêz* (Lat., rich). The word used in the Vulgate version for the rich man, in the story of Lazarus in Luke xvi, and thence often taken as a proper name, although it is in reality only a descriptive term.

DIVICIACUS. See **DIVITIACUS**.

DIVIDE (Lat. *dividere*, to divide). In physical geography, the crest line between the slopes of two . . . systems. The term is used, mostly in . . . States, synonymously with watershed.

DIVIDEND (Lat. *dividendus*, to be divided, from *dividere*, to divide). A fund, made up of principal or profits, set apart for distribution among a number of persons ratably entitled thereto; also the portion or share of each person so entitled. In practice the term is not in common use to describe a complete fund distributed once and for all to the claimants or owners, as in the division of partnership assets or the distribution, upon an accounting, of the assets in the hands of an executor or administrator; but it is rather employed to denote the sum available for partial or periodical payments out of such assets or out of current earnings. In this restricted sense it is entirely appropriate to the portion of the assets of an insolvent, or of a company in process of winding up, which is realized from time to time by the trustee or receiver and distributed among the creditors or shareholders. The most common use of the term, however, is to describe those profits or earnings of a corporation or joint-stock company which are set apart for distribution among the members and stockholders.

It will be noticed that such assets and earnings while yet unappropriated are not dividends, and that it is their formal appropriation to the purpose of distribution which gives them that character. As soon as this has been done, and not before, they are treated by the law as the property of the persons entitled thereto under the terms of the appropriation, and such persons may accordingly demand and recover them as "money had and received to their use."

As applied to corporations, the term "dividend" has been defined to be "that portion of the profits and surplus funds of the corporation which has been actually set apart by a valid resolution of the board of directors, or by the shareholders at a corporate meeting, for distribution among the shareholders according to their respective interests, in such a sense as to become segregated from the property of the corporation and to become the property of the shareholders distributively."

The declaration of dividends is one of the usual powers of directors, and, unless controlled by the charter or by-laws of the corporation, they may usually fix the amount of the dividend, and the time and place of payment, at their sole discretion, subject only to the obligation of good faith with the stockholders. Dividends cannot usually be declared out of the capital, but only from the profits; but there is no obligation on the directors to appropriate all or any particular portion of the profits to this purpose, though the contrary has been held in England. It has also been held in England

that dividends must be payable in money; but in the United States dividends are often paid in the stock, bonds, or scrip of the corporation. When dividends declared from time to time do not exhaust the profits, the surplus thus accumulated may be appropriated in whole or part as an "extra dividend" or bonus.

As between a person having a limited interest in corporate shares, as a life tenant, and the person entitled thereto in the future, the question may arise as to whether dividends earned but not declared during the ownership of the shares by the former, or dividends declared out of accumulated earnings, belong to the former as profits or to the latter as capital. Commonly this is solved by applying the rule, previously laid down, that no one becomes entitled to earnings until they have been appropriated in the form of a dividend. It is usually held also that extra dividends declared out of surplus earnings shall always be regarded as profits in the same way as those declared out of current earnings. See **CORPORATION**; **DIRECTOR**; **STOCKHOLDER**; **STOCK**; **DEBENTURE**; and the authorities referred to under those titles.

DIVIDERS. See **COMPASSES**.

DIVIDING ENGINE, or **RULING ENGINE**. A machine devised to rule fine lines at regular intervals by means of a diamond point or other sharp edge. The most common use of such machines is for the purpose of dividing the circumference of a circle into degrees and minutes or other divisions as is necessary in the construction of surveying and astronomical instruments, micrometer screws, spectrometers, and other physical instruments, as well as in many commercial machines; and also for the purpose of dividing a length into aliquot parts as in the making of meter rods and similar instruments. Another use to which they are put is that of the preparation of diffraction gratings (q.v.), in which it is necessary to have the means of ruling a great number of lines, exactly parallel and at exactly equal small intervals apart. Gratings are made with as many as 100,000 lines in a distance of five or six inches.

The first instrument for the ruling of gratings was made by Joseph von Fraunhofer (q.v.); others have been made by Rutherfurd, Rowland, and Michelson; but all are based on the same general principle. The machine consists of a cylinder on which a screw thread is cut and which carries a large nut, the two together being like an ordinary bolt and nut. The ends of the screw are held in yokes, so that it can turn on its axis, and the nut is held on "ways" parallel to the screw. Thus, as the screw is turned by a crank or otherwise, the nut advances or recedes. A cutting edge is set at some point above the screw, in such a manner that it can be made to make a line at right angles to the axis of the screw. The piece of glass or metal on whose surface the rulings are to be made is attached to the nut, and the operation is as follows: A line is made by the cutting edge; the screw is turned through a certain fraction of a complete revolution, e.g., one-thousandth, thus carrying the nut and the surface forward a small distance; a second line is ruled; the screw is again turned through the same angle as before; a third line is ruled, etc. Thus, if the pitch of the screw is 20—i.e., if there are 20 threads or spirals on the screw in each inch along its length—there will be 20,000 lines per inch ruled on the grating surface. The nut is split in two,

the halves being hinged at the top and having below two projections, or "wings." When the machine is to be used, these are clamped together. At the end of the ruling the wings are opened, and the nut, being thus released from the screw, can be pushed back to the starting point.

It is evident that the machine must be rigid, the "ways" exact, the screw of perfectly uniform pitch, the turning of the screw regular, the cutting of the line exactly straight. All modern machines are automatic; a large toothed wheel is attached to the screw at one end, and this turned by levers, one tooth at a time; the cutting edge is a diamond point which is allowed to drop on the ruled surface, is drawn across, then lifted, pushed back to the original position, etc. There are always periodic errors in the use of any dividing engine, occasioned by irregularities in the toothed wheel, the end of the screw which butts against some fixed support, and elsewhere. These may be counteracted by a device due to Rowland which depends upon the action of a lever resting on a cam attached to the axis of the screw. The end of the lever is rigidly fastened to a rod which is parallel to the screw, and to which is attached, by means of a short crank, a framework supported under the screw and free to move horizontally. Part of this framework consists of two steel rods parallel to the screw, between which the two "wings" of the nut can just move freely, as the nut is carried forward by the screw. Thus, if the cam raises its lever, the rod will turn, moving the framework holding the wings of the nut, and thus giving the nut a slight turn independent of the action of the screw. It is a matter, therefore, of trial to find a cam of such a shape, and to place it on the axis of the screw in such a position, that by its motion the irregular motion of the nut due to the irregularities of the machine may be made perfectly regular. The circular dividing engine used in making the scales of various instruments of precision likewise depends upon an accurate screw, and gear wheels and various refinements have been introduced in the design and construction of such instruments whose calibration curves are studied with great care. For a description of the construction of a "perfect" screw, reference should be made to the article "Screw," by Rowland, prepared for the ninth edition of vol. xxi of the *Encyclopædia Britannica*. A full description, with plates, of Rowland's dividing engine is given in *The Collected Papers of Henry A. Rowland* (Baltimore, 1902), in which the article on "Screw" is also reprinted. An interesting description of a novel type of circular dividing engine and its calibration by Stamper and Hall will be found in *Physical Review*, vol. xxx, No. 4.

DIVI-DIVI, dē-vē-dē-vē (Galibi or Carib word), or **LIBIDIBI**. The cured pods of *Cæsalpinia coriaria*, a tree which grows on the coasts of (1) (2) (3) (4) (5) and other parts of tropical America. They have been long used there for tanning, and have recently acquired importance as an article of commerce. Divi-divi is one of the most astringent substances known. The tree reaches a height of 20 to 30 feet, and produces about 100 pounds of pods annually. The pods contain tannin and gallic acid. It is said to tan leather with great rapidity. The United States imports annually about 300,000 pounds. See *CÆSALPINIA*.

DIVINA COMMEDIA, dē-vē'nā kōm-mā'-dē-ā. See DANTE.

DIVINATION (Lat. *divinatio*, from *divinare*, to divine, from *divinus*, divine, from *divus*, deity). A term employed to describe the quest of a knowledge of secret things, past, present, or future, by various supernatural methods, principally oracular responses and omens. As the origin of the word indicates, the idea is based on the assumption that human intelligence may obtain knowledge from the divine mind through media affected by divine influence. The Greek term *μαντική* (*τεχνή*) suggests the inspired intermediary *μάντις* ('seer'), a word which Plato and the Greeks associated with *μανία* ('inspired frenzy'). The contact of the divine mind with human intelligence was believed to be accomplished either through a medium directly, or by signs and omens which were interpreted by the medium. The Stoic philosophers recognized this difference in method (Cicero, *De Divinatione*, i, 6, 33, and ii, 11), and designated the first *ἀρεῖος*, *naturalis* ('artless'), i.e., the direct or natural method; and the second *ἑνρεῖος*, *artificiosa*, i.e., the artificial method. Bouché-Leclercq terms the first the intuitive and the second the inductive method, because the artificial class admits of some spontaneity and the natural something artificial.

The natural, the intuitive, method is very familiar as represented by oracles, a term used to denote both the seat of divination and the responses themselves. For these responses the seats of worship of divinities were regarded as favorite localities and were generally marked by some peculiar physical characteristic, as a cleft in the ground whence an exhalation arose by which the medium was made to pass into a trance. There were several methods in which information from the divinity was communicated by the oracles. *Divination by dreams* (oneiro-mancy) required experience in dreams and the interpretation thereof. Persons desiring revelation by this means would go to sleep in places thought to be haunted by dreams, such as tombs of heroes and temples of divinities. As the body must be inert and the mind passive, various means were employed to accomplish this, as refraining from wine and food for a certain period. Means were also taken to summon the dreams by incantations and by unusual conditions of sleeping, as when one lay on the skin of a ram slain by him. This method was known as incubation (*ἐγκομιση*). Such was the oracle of Amphiaraus at Oropus, near the spot where the hero became a god. Of this kind the most familiar oracles were healing shrines connected with the temples of Æsculapius. *Necromancy* was the method whereby revelation was conveyed by the shades of the dead who were summoned for the purpose. In Homer, Odysseus goes to the entrance of the lower world to consult the shade of Tiresias. These oracles were given at places recognized as approaches to the lower world, as Lake Aornos in Thesprotia, and Lake Avernus near Cumæ in Italy. *Chresmology*, or divination by frenzy (*vaticinatio* or *divinatio per furorem*), was the revealing of the will of the divinity by seers. Being in a state of frenzy, superinduced by exhalations or drafts of water from certain streams, or of blood, as of a lamb, they spoke forth the prophetic words either from a presentiment or an inspiration by the divinity, or from becoming, as was fancied, the incarnation of the divinity

for the time being. The most famous oracle of this class was at Delphi, situated on the side of Mount Parnassus in Phocis, which, originally belonging to Gæa, then to Themis, the representative of law and order, finally came into the possession of Apollo, whose priestess, Pythia, gave his answers by means of her cries.

The artificial or inductive methods of divination admit of the following classification: *Divination by instinctive acts of animals*. Under this heading is therefore placed ornithomancy, ichthyomancy, etc. This refers to revelations obtained from the behavior of birds and fishes, particularly of the former, who, being in the heavens, come close to the divinities and can act as messengers. With these should also be classed the instinctive or unconscious acts of man. Such was the divination by omens, so familiar to the Romans. The well-known story of Crassus is an illustration. Starting on his ill-fated expedition against the Parthians, he heard a man selling figs from Caunus, and crying "Cauneas," which sounded like *Cave ne eas* ('Beware of going'). Here we may also place the modern divining rod (q.v.) which is said to bend when held over concealed springs of water or mineral deposits. This custom is known in England as "dowsing." (Consult Murray, *New English Dictionary*.) *Divination by haruspication*. This method was the interpretation of the divine will by studying the entrails of victims. Practiced in very remote antiquity in the East, in Egypt, Cyprus, and Etruria, it was familiar to the Greeks of the fifth century B.C., but not in Homeric days. It passed from Etruria to Rome, where it served the purposes of statesmen (Cicero, *De Divinatione*, ii, 12). The nearest approach to this in recent days is palmistry, or reading the lines of the hands, and the old "reading of the speal bone," called omoplatoscopy or scapulimancy, which is the inspection of the lines in the shoulder blade. *Divination by fire* (empyromancy). This consists in observing the effect of fire from the altar on wood, or on the offering, or again in watching the movements of the smoke and the wine of a libation. *Divination by water* (hydromancy) consisted in the observation of objects cast into water. *Divination by lots* (cleromancy) was a method which required a movement consciously begun and directed by chance. Here may be placed *avinomancy*, which is the consideration of the movements of an axe placed on a post; *coscinomancy*, or the observing of the results of the turning of a sieve hung on a thread; or, again, *dactylomancy*, or the interpretations of the oscillations of a ring hung over a circular vase against which it strikes. This is a method of great antiquity and is found in Homeric days. Among the Romans *sortilegium*, or casting of lot, belonged to this experimental form of divination. Small tablets of wood, bone, or bronze were inscribed with various sayings and when shuffled and drawn gave the prophecy. A number of them have come down to our own times and are described in *Corpus Inscriptionum Latinarum*, vol. i, pp. 268-270. The term *sortes* was also given to selections from books used for a similar purpose. Compare with this the chance reading of the Scriptures. Lines from the great poets, particularly Vergil, were also employed as *sortes Vergilianæ*, as mentioned by Spartianus in his *Hadrian II*. In England Charles I is said to have opened to *Aeneid*, iv, 615, when consulting Vergil in the Bodleian Library at Oxford. Dice

were also used by the Romans in this way. *Divination by meteorology* is represented by the study of lightning flashes and interpretation of them. Such were the *signa ex cælo* interpreted by the augurs and haruspices. *Divination by astrology* was the most important in antiquity and consisted of predictions made after observing the heavenly bodies. It arose among the Chaldeans, then passed to the Greeks, and finally to the Romans, among whom the term for astrologers was *Chaldæi* or *mathematici*. See AUGURIES.

DIVINATION BY CUP. See CUP, DIVINATION BY.

DIVINE RIGHT. A term of ancient origin, which came into general use in the seventeenth century during the factious contentions of English Royalists and Parliamentarians. The Royalists maintained that, as "the Lord's anointed" and the immediate representative of the Deity, all power and government were vested in the king, who "could do no wrong"; a doctrine which relieved him from human responsibility. The Parliamentarians contended that the exercise of political power sprang from the will of the people, by what was termed "the social contract." The opponents of divine right included Milton, Algernon Sidney, and Harrington, and its chief supporters were Hobbes, Salmasius, and Sir Robert Filmer, whose *Patriarcha* contains a complete exposition of the theory. The idea can be traced through the Middle Ages and beyond, in the assumed "divine authority" of the magistracy; in the history of the Roman Catholic church it is found in the doctrine of the Pope's infallibility. The settlement of the crown on William and Mary ended the British controversy, but a similar controversy was revived in the discussions which caused the French Revolution.

DIVINE SONG. See BHAGAVAD-GITA.

DIVINE TRAGEDY, THE. A dramatic poem by Longfellow (1871), forming the first part of his trilogy *Christus*.

DIVING (from *dive*, AS. *dyfan*, causative of *dyfan*, to plunge). The act of working under water—either with or without mechanical aids to enable respiration—as in pearl and sponge fishing, the raising of sunken vessels, the laying of subaqueous foundations, or other operations under water. Formerly diving operations were confined mostly to pearl and sponge fisheries and were performed by divers who plunged beneath

the water, remained as long as they were able to do without respiration, and then returned to the surface with their load. It has been asserted that the pearl divers of the East acquired by practice the power to remain under water for 15 or 20 minutes. There is absolutely no truth in such assertions, as no such endurance is possible; two, and sometimes three, minutes under water is the limit of endurance of the most skillful divers unaided by mechanical means to support respiration. Most divers suffer severely from the continual efforts, in holding the breath; bloodshot eyes and the spitting of blood are common among them. This rude method of diving is but little used now, even in the pearl and sponge fisheries, where it is particularly applicable. Diving operations are now performed by means of diving bells or special diving dress.

Diving Bell. The *cacabus aquaticus*, or aquatic kettle, described by Taisnier as having been used by two Greeks in Spain, at Toledo, in 1538, in the presence of the Emperor Charles V and a multitude of spectators, is one of the earliest reliable accounts of a diving bell. From his description this must have been similar in principle and construction to the modern diving bell, but of clumsy dimensions, and wanting in efficient means of renewing the supply of air. Dr. Halley's diving bell, devised about 1714, was a wooden chamber, open at the bottom, where it was loaded with lead to keep it perpendicular in its descent. Strong pieces of glass were set in the upper part to admit light. Casks filled with air and loaded with lead were let down with the bung-hole downward; and from these a supply of air was drawn by means of a hose. Halley on one occasion with four companions descended to a depth of 54 feet and remained one and a half hours. The form of diving bell now in use was first constructed by Smeaton for underpinning the foundations of a bridge over the Lyne at Hexham in 1778 and then for the works at Ramsgate Harbor, England. The bell was of cast iron and weighed 50 hundredweight; its height, $4\frac{1}{2}$ feet; length, the same; and width, 3 feet. It sank by its own weight and was lighted by stout pieces of bull's-eye glass firmly cemented by brass rings near the top.

The principle of the diving bell will be easily understood by floating a piece of lighted candle or a wax match on a cork and then covering it with an inverted tumbler and pressing downward; the candle will descend below the level of the surrounding water and continue burning for a short time, although the tumbler be entirely immersed. The reason is obvious enough; the air in the tumbler, having no vent, remains in it and prevents the water from occupying its place, so that the cork and candle, though apparently under water, are still floating and surrounded by the air in the tumbler; the candle continues burning until the oxygen of the air is exhausted, and then it goes out, as would the life of a man under similar circumstances. If vessels full of air, like the barrels of Dr. Halley, were submerged, and their contents poured into the tumbler, the light might be maintained; but this could better be done if a tube passed through the tumbler, and air were pumped from above through the tube into the tumbler.

The modern diving bell, which is made of steel plates and is used chiefly for preparing the ground to receive massive concrete blocks used

in harbor construction, is supplied with air in this manner. It must be remembered that air is compressible and diminishes in bulk in proportion to the pressure, so that at a depth of about 33 feet in water it would occupy half the space it filled at the surface; if the inverted tumbler were carried to this depth, it would be half filled with water. A considerable quantity of air has, therefore, to be pumped into the diving bell merely to keep it full as it descends; the air thus compressed exerts a corresponding pressure and would rush up with great force if the tube were open and free. This is prevented by a valve opening downward only. When the diving bell has reached its full depth, the pumping is continued to supply air for respiration; and the redundant air overflows, or rather underflows, by the open mouth and ascends to the surface in bubbles. The diving bell is provided with a platform or seat for the workmen and suspended from a suitable crane or beams projecting from a barge or pier; men above are stationed to work the pumps and attend to the signals of the bellman. These signals are simply made by striking the sides of the iron diving bell with a hammer, and as sound is so freely communicated through water, they are easily heard above, or telephone communication may be established. Owing to their great weight and clumsy operation, diving bells are now seldom used in subaqueous operations, the modern appliance being the diving dress or diving armor. A recent application was in connection with the construction of the naval harbor works at Dover, England.

An account of early diving bells and apparatus will be found in Gerland and Trautmüller's *Geschichte der physikalischen Experimentierkunst* (Leipzig, 1893).

Diving Dress. In Schott's *Technica Curiosa*, published in 1664, is described a *lorica aquatica*, or aquatic armor, which consisted of a leathern dress, to protect the diver from the water, and a helmet. In 1721 Halley describes a contrivance of his own of nearly the same kind; its object was to enable the diver to go out from the bell and walk about; he was to be provided with a waterproof dress and a small diving bell, with glass front, as a helmet over his head, which was to be supplied with air by means of a tube from the diving bell. In 1798 Kleingert of Breslau invented a diving dress available for depths up to 20 feet. The head and body of the diver were encased in cylindrical tin-plate armor and his legs in leather breeches. Fresh air was conveyed to him and the vitiated air was removed by means of pipes.

In 1828 August Siebe in England devised an open-helmet diving dress, having a copper helmet and breastplate, with attached canvas jacket below which the air was allowed to escape, but to avoid the admission of water the diver was forced to keep a vertical position. In 1839, while working on the wreck of the *Royal George*, Siebe improved his dress, which straightway became standard practice and has since remained in use in Great Britain with few modifications and is essentially the type used in the United States. This form, a closed type of dress, is a waterproof costume with helmet of tinned copper, having circular glasses in front, valves to admit and discharge air, and a signal line to allow communication with those above water. The weight of the dress is about 275 pounds.

On the continent of Europe apparatus known

as the Rouquayol-Denayrouze apparatus from its inventors was first used in 1864. It is a steel air reservoir carried on the diver's back and supplied from a pump. It is more complicated than the usual form, but obviates the risk of the diver being blown to the surface under certain conditions.

In 1880 Fleuss invented a dress weighing only 20 pounds, which since it originally appeared has been much improved. This has no life line or air pipe, but a copper cylinder fastened to the back, carrying a supply of compressed oxygen with a suitable reducing valve and, under certain circumstances, apparatus for mixing air.

Other modifications and improvements of this idea have been made, and while it is not yet available at extreme depths the diver has great freedom of movement, being independent of hose and pump. The carbonic acid exhaled by the diver is absorbed by caustic soda in a receptacle fixed above the copper cylinder, while the air purified is breathed over and over again. In this dress the diver may remain several hours below the surface.

For lighting the diver's surroundings are and incandescent electric lights are used, as well as improved oil lamps supplied with air by force pumps. Slaters and signal lines and latterly telephones, a most important and desirable modern innovation, are used for purposes of communication. The greatest depth to which a man may descend with safety is 204 feet, equivalent to a pressure of 91½ pounds per square inch. This distance, actually accomplished by James Hooper at the wreck of the *Cape Horn* off Pichidanque, South America, is usually considered the record depth.

On all ships of the United States navy, except very small ones, there is a complete diver's outfit. Nearly all gunners' mates are now instructed in diving, and all recently appointed gunners and boatswains are conversant with the work, as are also the carpenters. Divers are used for examining the bottom or cleaning it, overhauling the strainers of submerged pipes, scraping the propellers, examining chains, looking for articles lost overboard, etc. Men who are qualified divers are given \$1.20 for each hour actually spent in diving in addition to the ordinary pay of their rating.

Bibliography. For a popular description consult Dunville-Fife, *Submarine Engineering of Today* (London and Philadelphia, 1914); also Boycott, *Compressed Air Work and Diving* (London, 1909); British Admiralty, *Report of the Committee on Deep-Water Diving* (ib., 1907).

DIVING BEETLE. An aquatic predaceous beetle of the family Dytiscidæ. These beetles are flat, oval, and, when not disturbed, hang head downward in the water with only the tip of the abdomen touching the surface. They may be distinguished by the threadlike antennæ. They are brownish black in color, sometimes with indistinct yellow markings. These beetles are very voracious and feed on other insects, worms, and even small fish, fly at night with ease, and frequently congregate about electric lights, and some forms make a sound both in and out of water. Their eggs are laid in the water and the larvæ are known as water tigers. The transformation of the larvæ is undergone in a cell in the earth. Nearly 300 species of this family are known. The two genera to which

the largest American diving beetles belong are *Cybister* and *Dytiscus*, distinguished by the disks on the tarsus, which are in four rows and similar in *Cybister*, while they are variable in *Dytiscus*. The medium-sized forms belong to the genera *Acilius* and *Colymbetes*, the former having the wings finely punctured, and the latter striated. The larvæ of all forms can easily be kept in confinement if fed on bits of cooked or raw meat. Consult Miall, *Natural History of Aquatic Insects* (London, 1903).

DIVINING ROD (often called *virgula divina*, *baculus divinatorius*, *caduceus* or *wand of Mercury*, rod of Aaron, etc.). A forked branch, usually of hazel, sometimes of iron or even of brass and copper, by which minerals and water are alleged to have been discovered beneath the surface of the earth. The rod, when suspended by the two prongs, sometimes between the balls of the thumbs, is supposed to show by a decided inclination the spot under which the concealed mine or spring is situated. The divining rod seems to have been known in all times, ancient and modern. It is clearly described by both Cicero and Tacitus, and an unbroken line of references to it can be traced from their days to this. Other powers are ascribed to the divining rod, but this is the chief. Many persons, even of some pretensions to scientific knowledge, have been believers in the occult power ascribed to this magic wand. Agricola, Sperlingius, and Kirchmayer all believed in its supernatural influence. Bayle, in his dictionary, under the word "abaris," gives some ingenious arguments both for and against the divining rod. In a work published in 1847 and 1851, entitled *On the Truth Contained in Popular Superstitions*, Dr. Herbert Mayo gives a curious collection of alleged discoveries made by this divining rod. Many are the possible explanations for this strange phenomenon, the facts of which cannot, seemingly, be disputed; even to-day some reputable scientists, Professors Barrett and Janet among them, accept these facts. Undoubtedly some natural cause or causes will in time be discovered that will throw light on this obscure phenomenon. For a full and interesting discussion of the subject, the reader must be referred to Professor Barrett's papers in parts xxxii and xxxviii (for 1897 and 1900) of the *Proceedings of the Society for Psychical Research*. Consult Pierre Le Brun, *Histoire critique des pratiques superstitieuses* (Paris, 1702), and P. L. L. de Vallemont, *La physique occulte; ou, Traité de la baguette divinatoire* (ib., 1752).

DIVISCH, dē'vish, PROCOPRUS (1696-1765). An Austrian scientist, born in Senftenberg. He entered the Præmonstrant Order and became pastor at Brendiz. In 1754—and thus two years after Franklin's kite experiment—he erected in an open field the first lightning conductor on the Continent. The apparatus was destroyed by the peasants, who attributed to it the drought of the succeeding summer. Consult Friesz, *Prokop Duisch* (Olmütz, 1884).

DIVISIBILITY (from Lat. *divisibilis*, divisible; from *dividere*, to divide). That property of quantity, matter, or extension, through which it is either actually or potentially separable into parts. Whether matter is or is not indefinitely divisible is a question which has occupied the minds of philosophers since very early times. The diffusion of odors through the air for long periods from odoriferous bodies

without their suffering any sensible change of weight, and the tingeing of great quantities of fluid by very minute portions of coloring matter, are cases commonly appealed to in proof of the great divisibility of substances. Abstractly speaking, matter must certainly be conceived as divisible without limit; for the progressive subdivision of matter is nothing but division of the space occupied by it, and the infinite divisibility of space has been demonstrated geometrically by Descartes. However, this abstract Cartesian demonstration does not prove that there is no limit to the subdivision of matter by processes actually taking place in nature. The atomic hypothesis, disregarding the philosophical question as to whether atoms *could not possibly* be broken into fractions, assumes that they *are not* broken up in any physical or chemical process whatever. The phenomena of radioactivity have shown that larger atoms (such as that of radium) may be broken up into smaller ones (like that of helium), so that the original assumption of the atomic theory requires modification. If it is true, as J. J. Thomson has suggested, that the atoms of matter are really complex systems made up of the atoms of electricity, then the last products of the division of matter ought to be atoms of electricity. And if these may still be regarded as material particles, then the further question might be asked: Are electric atoms divisible? But—at least in the present state of human knowledge—such questions are really nothing but idle speculation, devoid of genuine scientific interest. See GASES, GENERAL PROPERTIES OF; MATTER; MOLECULES—MOLECULAR WEIGHTS.

DIVISIBILITY (IN MATHEMATICS). See DIVISION.

DIVISION (OF. *division*, *division*, Fr. *division*, from Lat. *divisio*, from *dividere*, to divide). In logic, the process of distributing all the objects included in the denotation (q.v.) of a concept (q.v.) into mutually exclusive classes, each of which is marked off from the others by the possession of some distinctive attribute. Logical division must not be confounded with physical division. In the former the term denoting the whole (called genus) can be predicated of the resultant parts (called species, see PREDICABLES); in the latter such predication is not possible. Thus, when Cuvier divided his order of primates (q.v.) into *homo*, *simia*, *lemur*, and *vespertilio*, he performed a logical division because the term "primate" is predicable of every one of the parts obtained; e.g., it can be said that *man is a primate*. But when a man is dissected into head, trunk, feet, etc., the division is not logical, but physical, because the term denoting the whole cannot be predicated of the parts; we cannot say that *the head is a man*. Traditional logic generally gives the following rules for correct division: First, the division must be exhaustive; i.e., the sum of the denotations of the species must be exactly equal to the denotation of the genus. Second, the division must be exclusive; i.e., no object found in the denotation of any species must be found in the denotation of any other species. Third, in order to secure conformity to the above rules, the division should be based on some one characteristic in regard to which the various objects in the denotation of the concept to be divided differ from each other. This characteristic used as the basis of division is

called the *fundamentum divisionis*. Thus, when plane triangles are divided into scalene, isosceles, and equilateral triangles, the *fundamentum divisionis* is the relative length of the sides of triangles.

DIVISION. In mathematics, one of the four fundamental processes of arithmetic, the one by which we find one of two factors when the product and the other factor are given. The given factor is called the *divisor*, the given product is called the *dividend*, and the result (i.e., the required factor) is called the *quotient*. The definition of division leads to the following identity: $\text{dividend} = \text{divisor} \times \text{quotient} + \text{remainder}$. If the remainder is zero, the division is said to be exact. The common symbols for division are: $\frac{a}{b}$, $a \div b$; $a : b$, a/b , ab^{-1} , in which

a is the dividend and b the divisor. Two forms of division are recognized in elementary arithmetic, the one based on the idea of measurement and the other on the idea of partition. The former is the case of dividing one number by another of the same kind, and the latter that of dividing a concrete by an abstract number. Strictly speaking, however, all number is essentially abstract, so that the mathematical process is the same in any case. That is, the numerical work involved in $\$8 \div 2$ is the same as that involved in $\$8 \div \2 , viz., that involved in $8 \div 2$.

The usual tests of the correctness of division are: (a) multiply the quotient by the divisor and add the remainder, the result equaling the dividend; (b) compare the excesses of nines in the identity of division. See CHECKING.

Simple tests of the divisibility of numbers by 2, 4, 5, 6, 8, 9, 10, 11, are: (a) a number is divisible by 2, 4, or 8, if the number represented by the last digit, the last two digits, or the last three digits is divisible by 2, 4, or 8, respectively; (b) a number is divisible by 5 if it ends in 0 or 5, by 10 if it ends in 0; (c) a number is divisible by 9 or by 3 if the sum of its digits is divisible by 9 or 3 respectively, and it is divisible by 6 if it is even and the sum of its digits is divisible by 3; (d) a number is divisible by 11 if the difference between the sum of the digits in the odd and in the even places is divisible by 11. The simplest test of the divisibility by algebraic binomials is that of the remainder theorem (q.v.). The division of large numbers is generally facilitated by the use of logarithms (q.v.). For the origin of the present method of division and for improved forms, see ARITHMETIC.

DIVISION. In military organization, a body of troops, consisting usually of two or more infantry or cavalry brigades, to which are attached a proportion of auxiliary and special troops of the other arms. The term is sometimes used as a classifying title, as "the cavalry division," "infantry division," etc. The strength and composition of a division vary in times of peace according as alterations are made in tactical or organization dispositions and in time of war according to the needs of the work for which the division is formed. In the United States army a division in time of war consists normally of three brigades of infantry, one brigade of artillery, a regiment of cavalry, and the necessary engineer, signal, sanitary troops, and transportation. The *division* is the great administrative and tactical unit and forms the basis of army organization. In round numbers a division has about 20,000 men, 8000 animals, and 700 wagons.

When two or more divisions are combined to form a *field army*, an *auxiliary division*, made up of all arms, . . . heavy guns, may be attached to the . . . A division is the appropriate command of a major general. In Germany an infantry division consists of two brigades, to which, under the command of the general commanding, are attached four squadrons of cavalry, four batteries of artillery, each of six guns, and a battalion of riflemen, or, in some instances, pioneers. In some of the continental armies the *corps d'armée* corresponds in completeness to the United States field army, composed of two or more divisions. See ARMY ORGANIZATION.

In naval usage a division is a group of ships constituting a part of a fleet, or one of the parts into which the crew of a man-of-war is divided. See SHIP'S COMPANY.

DIVISION OF LABOR. In political economy, an expression designating, somewhat awkwardly, the fact that in modern production each workman performs a part only of the process of manufacture. His work is coördinated with that of others to complete the whole. The fact of division is dependent on the fact of coöperation, which is the essential feature. Foreign economists have deemed it wise to use the more general term "coöperation," but in English economics the term "division of labor" has become consecrated through the labors of Adam Smith, and it would be idle at this late day to substitute the more exact formulation. Adam Smith drew attention to the increased productiveness which results when, in the process of manufacture, the several operations are apportioned to different workmen, so that each workman shall perform continually one operation instead of performing several in succession. This is the narrowest view of the division of labor, and subsequent writers have extended the term so that it includes not only the separation of processes in one employment, but also the separation of employments. The fact that one man is exclusively a carpenter and another exclusively a smith enhances their combined production over what it would be if each were a jack-of-all-trades. Other writers have still further extended the notion and speak of a national division of labor, by which they would designate the peculiar aptitudes of certain nations for certain branches of production, and which under a system of unrestricted commerce would probably promote a contrast between the economic activities of the several parts of the world. The division of labor has become one of the commonplaces of modern industry, and we do not perhaps sufficiently realize how entirely the effectiveness of modern production rests upon it. It may be well to review briefly the advantages of the division of labor set forth with so much skill by Adam Smith, which subsequent experience has so amply verified. In the first place, it promotes in a high degree the skill of the laborer. By devoting his energies solely to one operation, he acquires in it a dexterity which could not have been obtained if his attention had been given to many things. The hand that daily performs the same task comes to do it almost automatically. With the better separation of labor it is possible to employ persons according to their capacities. While some operations require great strength, others demand nicety of touch and extreme delicacy of handling. The weak, who find no place in the

runder labors of agriculture or mining, find in manufacturing a place for their labor. Without discussing at this point whether the increase of the labor of women and of young persons has been a social benefit, we can readily see that the division of labor which has made it possible has increased the national production by practically increasing the number of laborers and diminishing the relative number of dependent persons. Another advantage of division of labor lies in the saving of labor and of time. The skilled workmen make better use of the materials intrusted to them than do those who are not trained, and thus prevent waste; while the continuity of employment practically increases working hours by saving the time which would otherwise be spent in passing from one employment to another. To realize what this means, one has only to compare the labors of the agricultural population, where division of labor is not practicable to the same extent as in other forms of production, with those of the artisan classes. Not the least advantage resulting from the division of labor is the stimulus which is given to invention by the concentration of energies upon distinct and definite processes. While it may be true that learned men have made some of the most noted inventions of our time, it is equally true that the many thousands of modifications of tools and machines which have made them feasible and workable have come largely from those who have been in daily contact with their operation.

The discussion which has been given here has been in view of the separation of employment in the operations of a workshop or a factory, but it must be equally obvious that like gains result from the differentiation of functions among the people generally from the increase of specialism, not only in trade and commerce, but also in professional and scientific activities. Nor need space be given to the demonstration of the fact that the division of labor between localities and between nations creates in each special aptitudes which might not otherwise be awakened, and thus increases the sum of gratifications which are in the reach of mankind at large. To offset these advantages, which are almost self-evident, there have been urged against the division of labor disadvantages of considerable weight. It has been contended that the production of a workman whose only knowledge was how to polish the point of a pin was a pitiable spectacle for which modern industry was responsible. Not only is it urged that such extreme specialization is deleterious to the intelligence and that it saps the vitality, but it has been pertinently pointed out that in the revolutions to which industry is subject such a man might find himself without a place and without a living. When the facts are as stated, there can be no question of the hardship caused the individual. But the case is probably extreme. While it is true that well-rounded workmen are less frequent to-day than formerly, it is also true that the mechanical operations of factories are not so widely dissimilar that one who is displaced from one type of factory might not find suitable employment in another, with somewhat similar operations, but with somewhat different materials. Nor should it be forgotten that in comparisons between the workman of to-day and the man of yesterday it is not infrequent that the average man of to-day is compared with the skilled man of yesterday, and that

while years ago there were many skilled carpenters, there were also many who were quite unskilled, and the man who at the present time performs a single operation in a planing mill has perhaps deteriorated from the skilled and efficient craftsman who was his predecessor, but has risen, on the other hand, from one who bungled at the trade because he had not the aptitude to acquire skillfully all of its processes, and was not permitted under the older organization to devote himself to that one in which he would have been most efficient. It is further pointed out that with the subdivision of industry and the increasing use of machines there is opportunity through the reduction of working hours for mental development outside, even if the mental stimulus which comes from the work itself is not so great as formerly. In short, the disadvantages of the division of labor which were set forth with so much apprehension by writers of 50 years ago have not in the development of things proved so serious in their effects upon the working classes as they appeared. There can be little doubt that during the century just ended the progress of the working classes, not only in their material welfare, but in their intellectual development, has been greater than in any preceding period of the world's history. See **POLITICAL ECONOMY; PRODUCTION.**

DIVITIACUS, or **DIVITIACUS**. A Druid and chieftain of the *Ædui* (q.v.). His tribe enjoyed a friendly alliance with the Roman government, and Divitiacus himself visited Rome, where Cicero conversed with him on the subject of Druidism (*De Divinatione*, i, 90). When Cæsar, in 58 B.C., refused to allow the *Helvetii* (q.v.) to migrate from their lands in Switzerland and settle in Gaul, he relied on the *Æduans* and Divitiacus to furnish supplies for his army; but Dumnorix, a brother of Divitiacus and a bitter enemy of Cæsar, had, according to Cæsar, by bribery and intimidation secured the chief power among his people, and the supplies were withheld. Cæsar learned the facts, suppressed Dumnorix, restored Divitiacus to power, and, with supplies thus assured, crushed the horde of *Helvetii* near the town of Bibracte (Cæsar, *B. G.*, i, 16 et seq.). Divitiacus remained a faithful ally of Cæsar during his further campaigns.

DIVONA. See **CAHORS**.

DIVORCE (Lat. *divortium*, from *divertere*, to go apart). Divorce, in modern law, is a dissolution of marriage, by public authority, at the instance of one of the parties, for a cause that has arisen since the establishment of the connubial relation. Divorces are sometimes granted by the legislature, but usually by the courts under general laws. A judicial declaration that two persons who have gone through the form of contracting marriage are not husband and wife (as in the case where one of the parties was already married) is not a divorce; nor is the term "divorce" properly applied to an annulment of marriage for a cause that antedates the marriage (e.g., impotence or fraud). Again, a judicial separation which merely relieves the parties of some of the duties and suspends some of the rights connected with the connubial relation is not a divorce, for divorce dissolves the connubial bond itself.

History of Divorce. In early society the husband usually had the right of repudiating his wife, originally, perhaps, at pleasure, among some races only for cause. Primitive causes

were witchcraft, drunkenness, barrenness, adultery. In those communities in which the man became a member of his wife's family, power to repudiate him was usually accorded to her or to her kinsfolk, as was the case among some tribes of North American Indians. Among the Athenians the husband could dismiss his wife at pleasure, and the wife could leave the husband with the consent of the magistrate (*archon*). In ancient Rome the rules governing divorce depended upon the form of marriage. If the parties had entered into a religious marriage (*confarreatio*), divorce was possible only by another religious ceremony (*diffarreatio*), which, like the marriage, required the coöperation of the priests. If the marriage was in form a purchase (*coemptio*), the wife could be reconveyed into her original family only for grave misconduct. If, however, the marriage was "consensual"—and this type of marriage became general in the later Republic—it was dissoluble by dissent; i.e., either party could repudiate the other. To the Romans of the early Empire this freedom of divorce seemed morally right; and as late as the third century of our era the Roman jurists held that a promise not to exercise the right of divorce under any circumstances was an immoral promise. Even when the Empire became Christian, the right of divorce at will was not abolished; all that was done was to impose pecuniary disadvantages upon the party who exercised the right of divorce without good cause, or upon the party whose misconduct gave good cause for divorce. In the view of the Christian Church, however, marriage was a sacrament, and the matrimonial relation indissoluble; and in the Middle Ages, when the Church courts obtained jurisdiction over marriage, this view determined the law of Europe. Marriages might be declared null because of impediments which existed at the time of marriage, but marriages could not be dissolved because of any subsequent misfortune or misconduct. This is still the law in some of the European states, e.g., in Italy, Spain, and Portugal, and in Austria so far as members of the Roman Catholic church are concerned. Divorce reappeared with the Reformation and was part of the programme of the French Revolution; and in the great majority of the European states (and in Austria, as regards non-Catholics) divorces can be obtained at the present time on various grounds—always for adultery and for extreme cruelty, usually for desertion, and in some states on the ground of conviction of an infamous crime and of incurable insanity. Incompatibility, strained relations, unconquerable aversion, etc., are grounds usually for separation only; but in some states a separation obtained on such grounds may, after a term of years, be converted into an absolute divorce. Divorce by mutual consent was permitted by the Code Napoléon, and also, when the marriage was childless, by the Prussian Code of 1794; but divorce on this ground is not permitted by the existing legislation of France nor by the German Imperial Code. In the former country the subject is now regulated by legislative act of 1883. The idea that marriage is something more than a private relation, that it is the basis of the existing social order, and that society is interested in its maintenance, finds expression in it, not only in the rule that divorce is to be granted only for cause, but in the practice of making the official who corresponds to the American district at-

torney a party to every proceeding for divorce or annulment of marriage.

In England there was no common-law jurisdiction in matrimonial causes prior to the creation of a divorce and matrimonial court by Act of Parliament in 1857, and the ecclesiastical courts, to which that jurisdiction had been confided, consistently held the marriage tie to be indissoluble. Accordingly, before Jan. 1, 1858, when the Matrimonial Causes Act (20 and 21 Vict., c. 85) went into operation, divorces could be obtained in England (as is still the case in Ireland) only by act of Parliament. It was, indeed, possible to obtain a declaration of nullity of marriage on the ground of consanguinity, previous marriage of one of the parties, mental or physical incapacity, coercion, or fraudulent representations as to the essentials of the relation, as, e.g., false personation. But the judgment so obtained was not a decree of divorce, but a declaration that the marriage tie between the parties had never really been contracted. A wife may now obtain a divorce on the ground of the husband's incestuous adultery, or of his bigamy with adultery, or of rape, or of sodomy, or of adultery coupled with gross cruelty, or of adultery coupled with desertion without reasonable excuse for two years. The husband may obtain a divorce on the ground of the wife's adultery without other cause. But neither party can obtain a divorce on the ground of desertion alone, however long continued. Nor will a divorce be granted should it appear that husband or wife has been guilty of recrimination by committing the same offense, or that there is collusion between them in order to procure the divorce. Parties also who have condoned the offense—i.e., who after it has been discovered have consented again to live together as husband and wife—will not be allowed to obtain a divorce. In order to guard against fraud by parties contriving to procure a divorce, power is given to the Queen's proctor, by 23 and 24 Vict., c. 144, to interpose, in case he have reasonable ground to suspect collusion or recrimination, in order to oppose a petition for divorce. The court may order the husband to pay a divorced wife a certain sum for her maintenance during their joint lives. After decree of divorce the offending party may marry again, even with the paramour. But it is enacted, 20 and 21 Vict., c. 85, that no clergyman shall be compelled to solemnize the marriage of any person who has been divorced. By the acts of 1857 and succeeding years parties are also entitled to obtain a judicial separation on the ground of adultery, cruelty, or desertion. Judicial separation is declared to be in place of a separation *a mensa et thoro*. A married woman, having obtained a decree of judicial separation, is declared to be in all respects as a *feme sole* in regard to any property that she has or may acquire. Even before obtaining a separation a woman deserted by her husband may obtain from the court a protection for any property she may acquire by her own industry.

In the United States, during the Colonial period, the legislative bodies in the several provinces gradually assumed the power of granting divorce, and after the Revolution the system of divorce by legislative enactment became uniformly established. Experience of this system proving its defective character, the jurisdiction over divorce cases was generally transferred to the courts of equity, and in many of the State

constitutions it was expressly provided that divorce by legislative act should not be permitted. There is no national control over divorce in this country, and, as the States make their own laws regulating the dissolution of marriage, the greatest diversity in their treatment of the subject has arisen, some of them refusing divorce altogether, or granting it only for a single cause, and others going to the extreme of freedom in permitting the dissolution of the marriage bond.

This want of uniformity makes it impossible to lay down general principles as to the grounds on which divorce is granted in the United States as a whole, and a brief outline of the laws relating to the subject in the different States is all that can here be attempted. There are laws granting divorce on certain specified grounds in all the Commonwealths and Territories except South Carolina. In the latter State divorce is not granted on any grounds whatever, either by the courts or by legislative act, and the results of this state of things offer an interesting subject for investigation to those who maintain the strict canonical view with regard to the indissoluble nature of marriage. It has been remarked that the prevalence and partial legal recognition of concubinage are the effects of this attitude towards the divorce question in South Carolina. (Bishop's *Marriage and Divorce*.) In all the other States infidelity and violation of the marriage vow are recognized as valid grounds for divorce. In New York adultery alone warrants absolute divorce in the eye of the law. Willful desertion is generally considered a sufficient cause, but the period of absence necessary to substantiate the complaint varies in the different States from one to five years. Other grounds generally recognized are habitual drunkenness; conviction of felony; intolerable, extreme, or repeated cruelty; and continuous desertion. Among the various grounds less generally admitted are insanity, failure of the husband to provide for the wife; willful neglect for three years; absence without being heard from for three to seven years; separation for five years; ungovernable temper; cruel treatment, outrages, or excesses, such as render living together intolerable; notorious immorality of the husband before marriage, unknown to the wife; gross misbehavior or wickedness; gross neglect of duty; attempt on life; refusal of the wife to move into the State; three years with any religious sect that believes the marriage relation unlawful; joining such a sect and refusing to cohabit for six months.

Such are the various grounds on which the marriage tie may be dissolved in the United States; but condonation, or collusion, or connivance, with the purpose of procuring a divorce, is in all States regarded as a bar to the dissolution of marriage. In Georgia divorce is granted only after the same verdict has been reached by two juries at different terms of the court. In Connecticut, Illinois, Kentucky, and Missouri, the divorced parties may remarry without restriction. In Massachusetts either party may remarry, but the defendant must wait two years and get the permission of the court. In Virginia a decree of the court may restrain the guilty party from marrying again; and in Maine the parties cannot marry till after two years without the court's permission. In New York the plaintiff may remarry, but the defendant is not permitted to do so in the former's lifetime.

except by the express permission of the court, or if, after five years have passed, the plaintiff has remarried, and the defendant's conduct has been uniformly good during the interval. Violation of this rule is punished as bigamy, even when the other party has remarried. In Delaware, Pennsylvania, and Tennessee, the party divorced for infidelity to the marriage vow cannot marry the partner in guilt during the lifetime of the former spouse; nor in Louisiana at any time, such marriage in the latter State being considered bigamy.

From the conflict of laws in various countries on the subject of divorce, questions have frequently arisen as to the competency of a tribunal having power to annul a marriage contracted elsewhere. In the absence of personal service upon the defendant many States refuse to recognize such divorces, and much confusion results as to questions of bigamy, dower, children. In the case of *Estes v. The State*, 201 United States Reports, 562, it was decided by the Supreme Court in 1906, four justices dissenting, that a divorce granted in a State where the defendant is not domiciled, without personal service of process or a voluntary appearance by the defendant, though valid in the State where decreed, need not be recognized by any other State. The courts will not recognize a transient visit to a foreign country as sufficient ground to sustain a divorce there granted. See CONFLICT OF LAWS; DOMICILE.

Statistics. Divorce, in its broader social aspects, can best be introduced by a summary of statistics drawn from various official sources. The best authorities are the report on *Marriage and Divorce* prepared by Carroll D. Wright, United States Commissioner of Labor, in 1889, and covers the period 1867-86, and the Report of

1071 in 1867, 2606 in 1886, and 5943 in 1906. Michigan divorces increased from 449 in 1867 to 1339 in 1886 and 3259 in 1906. Vermont had 157 in 1867, and, with a slight increase of population, had 301 in 1906. All these States have several statutory grounds of divorce. Changes in the statutes and in the administration of the various county courts in part account for conditions in Vermont and Connecticut and perhaps one or two other of these States.

New York, which grants divorce for adultery only, and New Jersey, which adds desertion (the most easily abused of all causes, unless it be the former "omnibus clause" of Connecticut and a few other States), are instructive examples of another kind. New York granted 771 in 1867 and 1006 in 1886, an increase of less than half the increase of population. In 1906 New York granted 2069 divorces, an increase of 100 per cent in divorces in a period in which population increased 50 per cent. New Jersey, with its additional and easily misused cause of desertion, granted 60 in 1867, 286 in 1886, 292 in 1893, and 530 in 1906. New York, with one cause, and that one difficult of proof, grants more divorces in proportion to population or to marriages than New Jersey, though the latter adds desertion. The explanation is chiefly in the difference of administration. In New York divorces are granted in each county and city, while in New Jersey divorce cases go to one court—the highest in the State—whose chancellors require written testimony and sift it with great care.

In the West high divorce rates prevail, but no higher than some already given. The increase of population there is so great that figures are misleading, unless compared with population. The growth of divorce in the South is indicated by the following table:

STATE	Divorces 1867	Population 1867 U. S. est.	Divorces per M. pop.	Divorces 1886	Population 1886 U. S. est.	Divorces per M. pop.	Divorces 1906	Population 1906 U. S. est.	Divorces per M. pop.
Alabama. . . .	78	987,154	0.08	662	1,413,045	.47	2,162	2,014,337	1.07
Arkansas . . .	121	469,764	0.26	646	997,939	.65	2,428	1,469,298	1.66
Kentucky. . .	292	1,271,415	0.23	757	1,774,660	.43	2,050	2,232,812	0.92
Mississippi. .	49	816,939	0.06	504	1,226,397	.41	1,930	1,698,774	1.14
N. Carolina. .	21	1,047,740	0.02	163	1,530,670	.11	380	2,081,298	0.18
Tennessee. . .	287	1,213,905	0.24	801	1,677,455	.48	2,172	2,119,118	1.03

the United States Census Bureau on Marriage and Divorce, published in 1908, which covers the period 1887-1906. The annual reports of eight or nine States only, and of various European countries, give figures for later years.

In the 20 years 1867-86 there were found to have been 328,716 divorces in the United States whose libels or records were discovered. The number of divorces in the period 1887-1906 was 945,625. The figures of a few typical States may be cited: Connecticut granted 500 in 1867 and 557 in 1906, being one of the two or three States where divorces increase more slowly than the population. New Hampshire granted 136 in 1867 and 473 in 1906. Ohio granted 901 in 1867 and 4781 in 1906. Indiana had 1096 in 1867, the largest number for that year in any State, and 1655 in 1886. But in 1900 there were 4699, and, in 1906, 4048. Pennsylvania granted 575 in 1867, 1889 in 1886, and 3027 in 1906. Illinois granted

In the South as a whole the movement was slow in the first part of the period, but was greatly accelerated later. Technically 16.3 per cent of all the divorces in the United States in the period 1887-1906 were granted for adultery, 38.9 per cent for desertion, 21.8 per cent for cruelty, 3.9 per cent for drunkenness, and so on. But these figures are of little value as indications of the real causes. The wife is the applicant in about two-thirds of the cases—often, it should be noted, as a personal convenience to the parties. In the period 1887-1906 approximately three-fourths of the applications for divorce were granted. In a little over two-thirds of the cases the libelee was a resident of the State in which the divorce was granted; in 12.6 per cent of the cases the residence of the libelee was unknown. This shows that migratory divorces, though many in number, are only a small part of the entire number granted in the country. The abuse of

our conflicting laws and the uncertainty to which they expose our people are very serious. But the real gravity of the situation is in the almost universal prevalence of divorce in all parts of the country, both in city and rural communities, though generally somewhat less in the latter than in the former.

Apparently more divorces in this country occur in families where there are very few or no children and at the other extreme, where children are very numerous. The latter fact is due probably to the desertion by fathers of large families among the lower classes. One or two States have attempted to check this by statutes making culpable neglect to support one's family a misdemeanor.

European figures are also instructive. Divorces or separations—the latter chiefly in Catholic countries—are as follows: Austria granted 883 in 1891 and 2309 in 1906; Belgium 130 in 1867 and 618 in 1906; France, 2181 in 1867 and 2806 in 1882. In 1885, the first full year under the Law of 1884, there were 6245, 7460 in 1897, 8431 in 1902, and 7019 in 1906. England and Wales granted 130 in 1867 and 670 in 1906; Scotland, 32 in 1867 and 169 in 1906. The German Empire granted 3942 in 1881, 12,180 in 1906; Prussia granted 2329 in 1881, 5699 annually during the period 1895–99, and 7539 in 1906; Bavaria granted 270 in 1867 and 746 in 1906; Saxony, 396 in 1867, 935 in 1893, and 1470 in 1906. In Italy the movement fluctuated a good deal from year to year. In 1891 there were 591 legal separations, in 1904, 859. In the Netherlands there were 133 divorces in 1867 and 995 in 1906. Norway granted 33 in 1870 and 366 in 1906. Sweden granted 128 in 1867 and 448 in 1905. Rumania granted 276 in 1871 and 1800 in 1904. Switzerland, in six cantons, granted 190 in 1867 and 287 in 1875. The next year, under the uniform federal law, the same cantons granted 444, and 396 in 1886. In the entire country, under a uniform law, there were 1102 in 1876; 1036 for each of the two following years; there were less than 900 on the average until 1896, when they rose to 1058, being 1053 in 1900. The ratio to marriage is generally about 1 to 22, being the highest of any country in Europe and about the same as in Massachusetts.

Divorces in Canada are very few, there being only 19 in 1904. Of these, 8 were granted in Nova Scotia and New Brunswick, where the courts and not the legislative bodies have jurisdiction of the subject. In Australia there were 140 divorces in 1890, 340 in 1896, and 339 in 1905. New Zealand granted 16 in 1884, 25 in 1893, and 152 in 1906. In Japan the divorces for several years are about one-third the marriages. Until recently public law there exercised no control over marriage and divorce, these being left to the families immediately concerned. As a rule, the divorce rate in the United States is several times greater than in Europe. There are courts of divorce in all of the nearly 3000 counties in the United States, except in South Carolina and New Jersey. A single divorce court exists in England; one in each of the 28 judicial districts of Germany, while there is one in each of the 79 départements of France. The presence of several statutory grounds for divorce and their phraseology, rather than the technical number of causes, and the practice of the courts in regard to their interpretation, affect the number

granted. The prevailing local sentiment may perhaps be considered a still more influential factor in determining the number.

The strong legislative movement for greater freedom of divorce of the past century has been succeeded in many jurisdictions by a somewhat reactionary tendency. This appears in the removal of the "omnibus clause"—that giving general discretion to the courts to act beyond the definitive statutes—from the statutes of Connecticut and other States; in the raising of the period of residence from three to six months to one or more years in several States and all the Territories; in requiring a period of six months or more to intervene between the granting of the decree and its final issue to the parties; and in striking out all grounds for divorce in the District of Columbia except one. The Imperial law of 1900 in Germany reduces the causes to about four. It prevents the abuse of the plea of desertion by requiring, before a decree is granted, a preliminary suit for the restitution of conjugal rights and allows a year for the accomplishment of this object. Improved marriage laws have also helped in the matter of divorce.

Uniform Laws. The problem of uniformity took on a new aspect on the appearance of the government report of 1889 and the discussion that preceded and followed. The value of national legislation, under constitutional amendment, in restricting the number of divorces, it was then seen, might be very small. The obstacles in the way of getting three-fourths of the States to consent to it, and of enforcing it in localities where public sentiment would be hostile, appeared very great. Then the transfer of the care of marriage and divorce to the Federal authorities or to State regulation under Federal provision, with its effect on laws of inheritance and the like, and upon our present system of division of powers between the Federal and State . . . opens many serious and difficult Consequently most thoughtful students of the problem have felt that the present experiment, in which thirty-four States and Territories are already represented, of trying to secure uniformity by enacting the bills their commissioners on uniformity prepare and recommend, should have fair trial as the better way at present of either gaining all that can be accomplished or of preparing for the constitutional amendment itself, should that be found necessary.

The Social Movement. It is evident that there is a profound and widespread social movement going on beneath the great variety of law, religion, and other conditions through which this movement finds expression, and which is most marked in the United States. Until recent years, and even now, divorce is treated chiefly in its legal or ecclesiastical phases. This treatment has also been individualistic to a degree. That is, both church and state have regarded chiefly the two individuals directly concerned, with some consideration of the interests of the church or state. But the family has been almost entirely overlooked. The canon law, the writings of the early fathers, and, in fact, the great body of literature on the subject, are singularly lacking in direct attention to the family as the real subject in the discussion of divorce. The term "marriage" has been used to cover both the formation of the marriage and the subsequent relation. Two

views of the relation and its dissolution grow out of this. One tends to make the relation a mere contract from beginning to end and therefore subject to be dissolved, like any other contract, at the will of the parties. The other insists that a *status* is created by the original contract, and that it is this *status* or relation with which divorce deals. This is indeed the legal view of the relation. But rarely is attention called to the fact that the *status* arising from the contract of marriage is not merely a relation of the two contracting parties, as in a partnership, e.g., but a family relation, thus in reality making divorce the legal dissolution of a family instead of individual relief from a contract or a personal status.

The Roman Catholic church has held to a consistent course in its ecclesiastical discipline, but has generally been compelled to share its control of divorce in recent times, in the more progressive countries with the state. In Russia the Orthodox Greek church and other confessions are allowed to administer, in all affairs of marriage and divorce, according to their own rules. Austrian law also adjusts itself to the different faiths of its subjects. And divorce laws, in their grounds for divorce, usually follow the religious opinions of the people.

The condition of what may be called the social strata of a period or country helps to shape the customs or laws of marriage and divorce. Among the early peoples of the Mediterranean these subjects were entirely within the control of the families immediately concerned, as in Japan until recently. The three kinds of Roman marriage were the expression of as many types in Roman society. As the early family yields more and more of social function to the state, the individual and relations of contract gradually supplant the family and those of *status*. All intermediary social forms, especially those of the domestic and communal type, tend to shrivel and lose their functions. Historically the increase and prominence of divorce have marked decaying civilizations. Whether the increase of the last 30 years will continue in the United States remains to be seen. There is an element of truth in the claim that the increase of divorce is in one sense the incident of social health. This rests, however, on certain assumptions concerning those who seek divorce which are of limited application.

Christianity came when the Roman world was far along in social disintegration. Early Christianity necessarily sought men as individuals and dealt with them as such. Marriage, divorce, celibacy, chastity, were all considered chiefly with regard to their effect on individual well-being. Their social, institutional bearings were ignored, unless it was in respect to the Church. The family is hardly named in the canon law, which was cast in the matrix of Roman law when in its later stages of individualism, in the regulations of Protestant churches. The emphasis of the Reformation on the individual, the art of printing, the use of gunpowder, the beginnings of modern science, and the discovery of America, all increased the power of the individual. Later, the ethical and political theories of Grotius, Hobbes, Locke, Rousseau, Blackstone, and Jefferson, the earlier schools of political economy, the American and French revolutions, the rise of the modern industrial system, and still later the use of steam and electricity, have all done much to accelerate

those changes by which the individual and the largest social combinations have absorbed the attention of society at the expense of all domestic and commercial groups. The evangelistic work of the last century, the temperance and the anti-slavery reforms, and the advancement of woman through assertion of her rights, should also, for similar reasons, be named as directly or indirectly contributory to the increase of divorce. That the general result is good as a whole may be fully conceded without denying the incidental evils. The increase of divorce and changing opinions and practice regarding marriage and other incidents of the family in this light seem to be the result of changes in the constitution of Western civilization. How far the disintegration and reconstruction of families is consistent with the health and growth of the social body has become a question of first importance in social science.

Change of Treatment. The growth of social science, especially in the form of sociology taken in relation to the social sciences, much as biology is related to its kindred sciences, is gradually but surely changing the discussion of divorce. For from this point of approach it is soon perceived that the family is the real object of study, and that marriage and divorce, as well as other of its incidents, are acts formative or destructive of the family. This puts the subject on a new ground. Historical sociology reveals the place of the family, and with it that of property, a subject always wrapped up with that of the family in early society, and in the development of civilization in all its more important phases. The scientific analysis of the present social order shows how the monogamous family embodied in the home has become to the social structure what the cell is to the human body. For the question of divorce compels us to ask: "What is marriage? What is the family? How far does the family, in its structure and principles, enter into the national constitution of a people? Can we hold to theories of the family which we have repudiated in our treatment of the state? Are the family and church and state of the same nature? Can democracy be allowed to go to the extreme of individualism, and end in the dissolution of the state and the family by mutual consent?" Most of the discussions of former years in religious circles in this country, and even now, have not got much beyond the old method of the treatment of divorce as the chief concern of two individuals, through the application of the precepts of individual morality. The different religious bodies have busied themselves with their respective tenets, increasing the number of justifiable grounds for divorce and the practice allowable under them, many assuming that the Founder of Christianity legislated on the subject for His Church, or perhaps, for both church and state. These things are being reiterated with much vehemence in many quarters. They strengthen many in the old faith and probably convert some others to it.

But the scientific study of society which has come about and rapidly spread in our higher educational institutions within the last 25 years, and the modern methods of biblical interpretation, have combined to force considerable change already. In some quarters at least the method of threshing over the old ground with grammar and lexicon, with the addition of mere archaeological information, is giving way, and attention

is turning to the underlying social factors in the problem. The chapters on "The Family," in Prof. Shailer Matthews's *Social Teaching of Jesus*, and in Prof. Francis G. Peabody's *Jesus Christ and the Social Question*, with some recent books on social ethics, may be cited in evidence of a change that is going on in the method of treatment by which the family has come to the front, both in scientific and religious circles, and marriage and divorce made its incidents rather than treated as separate subjects. It is too early to predict definite results, though the movement is one of much promise.

The chief recent periods of discussion are as follows: In England, over the Divorce Law, by Mr. Gladstone and others in 1857; in Connecticut, in 1866-69, when President Woolsey, of Yale, and Professor Hovey, of Newton Theological Seminary, published small volumes on the subject; in Switzerland, in 1875, when a federal law was enacted; in France, over the Law of 1884, by M. Bertillon, M. Naquet, and others; in New South Wales, over the Law of 1892, by Sir Alfred Stephen; in Japan, about the same time, when divorce first came under the control of the state; and in Germany, when an Imperial law went into effect, Jan. 1, 1900. The discussion in the United States was renewed in 1878. The society now known as the National League for the Protection of the Family has had an important part in the discussion of this period.

DIVOT. See FEAL.

DIX, DOROTHEA LYNDE (1802-87). An American philanthropist and writer of juvenile books, born at Worcester, Mass. She was noted for her interest in the unfortunate and criminal classes. During the Civil War she was superintendent of hospital-nurses. In the course of labors to improve the condition of paupers, lunatics, and prisoners she visited every State east of the

Rocky Mountains and procured ameliorative legislation in many of them. She published: *The Garland of Flora* (1829); *Prisons and Prison Discipline* (1845); and a great number of memorials on philanthropic subjects. Of many books for children, *Conversations about Common Things* and *Alice and Ruth* are typical. Consult F. Tiffany, *Life of Dorothea Lynde Dix* (Boston, 1890).

DIX, JOHN ADAMS (1798-1879). An American statesman and soldier, born at Boscawen, N. H. He entered the army as a cadet in 1812, served on the Canada frontier throughout the War of 1812, and in 1819 became the aid of General Brown, then commanding the Northern Department. In 1826 he was sent on a special mission to Denmark and in 1828 resigned his commission (of captain) to study and practice law in Cooperstown, N. Y. He soon became prominent in politics and was adjutant general of New York from 1830 to 1833 and Secretary of State and Superintendent of Common Schools from 1833 to 1840, besides being a prominent member of the "Albany Regency" (q.v.). He was chosen a member of the Assembly in 1842 and from 1845 to 1849 was a member of the United States Senate. In 1848, when the Democratic party divided on the question of the extension of slavery, he went with the Free-Soil wing, and was their candidate for governor, but was not elected. From January to March, 1861, he was Secretary of the Treasury under President Buchanan and as such endeavored to have all the revenue cutters in Southern harbors sent north before the beginning of hostilities. Among these two cutters from New Orleans were ordered to New York. The captain of one of them refused to obey the order, and Dix immediately telegraphed to have him arrested and treated as a mutineer if he offered any resistance, closing the dispatch with the words: "If any man attempts to haul down the American flag, shoot him on the spot." In 1861 Dix was appointed major general of United States volunteers and was placed in command of the Department of Maryland. In May, 1862, he was sent to Fortress Monroe and immediately after the New York draft riots (q.v.), in July, 1863, was sent to New York to command the Department of the East, which position he retained until July, 1865, when he returned to civil life. Subsequently he was Minister to France from 1866 to 1869 and from 1873 to 1875 was Governor of New York. Besides miscellaneous papers, he was the author of: *Resources of the City of New York* (1827); *Decisions of the Superintendents of Common Schools of New York, and Laws Relating to Common Schools* (1837); *A Winter in Madeira and a Summer in Spain and Florence* (1850); *Speeches and Occasional Addresses*, 2 vols. (1864). Consult Morgan Dix, *Memoirs of John A. Dix* (New York, 1883).

DIX, JOHN ALDEN (1860-). An American Democratic politician, born at Glens Falls, N. Y. He graduated from Cornell University in 1883, and entering business became president of the Iroquois Paper Company, treasurer of the American Wood Board Company, vice president of the Blandy Paper Company, and manager of the Moose River Lumber Company; also vice president of the First National Bank of Albany. In 1904 he was a delegate to the Democratic National Convention, in 1908 Democratic nominee for lieutenant governor and chairman of the Washington County Democratic Committee, and

in 1910 chairman of the Democratic State (New York) Committee. From 1910 to 1912 he was Governor of New York.

DIX, MORGAN (1827-1908). An American Episcopalian clergyman, the son of Gen. John A. Dix. He was born in New York City and graduated at Columbia in 1848 and at the General Theological Seminary in 1852. Three years later he became assistant minister, and in 1862 rector, of Trinity Church, New York. He was, in a number of successive general conventions of the Episcopal church, elected without opposition as president of the House of Clerical and Lay Deputies, an honor which advancing age compelled him to decline in 1901. He published commentaries on Romans (1864) and Galatians and Colossians (1865); *Lectures on the Pantheistic Idea of an Impersonal Substance Deity* (1865); *Lectures on the Two Estates* (1872); *Memoirs of John A. Dix* (1883); *The Gospel and Philosophy* (1886); *The Sacramental System* (1893); *A History of the Parish of Trinity Church* (4 vols., 1898-1906).

DIXEY, HENRY E. (1859-). An American comedian. He was born in Boston and at the age of nine years became a member there of the Howard Athenaeum Company, taking the part of Peanuts in *Under the Gaslight*. His subsequent experience included rôles in *Cinderella at School*, *The Mascot*, *Pinafore*, and a great variety of other plays. In 1883 he was engaged at the Bijou Theatre, New York, in *Adonis*, the character in which he made his greatest reputation. In 1894 he became a member of Daly's company for a season. Of his later performances, the most noteworthy is his creation of David Garrick in Stuart Robson's production of *Oliver Goldsmith* (1900). In 1911 he appeared with Mrs. Fiske as the Marquis of Steyne in *Becky Sharp* and as Peter Swallow in *Mrs. Bumpstead-Leigh*, and in 1914 played in Mackaye's *A Thousand Years Ago*.

DIXIE. 1. A Northern ballad of the Civil War, by T. M. Cooley. 2. A very popular ballad, by D. D. Emmett (1859), originating with Bryant's minstrels in New York and first performed at Mechanics' Hall. It was appropriated by the South and became one of the great Confederate battle songs of the Civil War. 3. A Confederate war ballad of the Civil War, by Albert Pike (1861), which first appeared in the *Natchez Courier*. See **DIXIE'S LAND**.

DIXIE, LADY FLORENCE CAROLINE DOUGLAS (1857-1905). An English explorer, writer, and champion of woman's rights. She was born in London, the daughter of the seventh Marquis of Queensberry, and married Sir Alexander Beaumont Churchill Dixie, Bart., in 1875. She spent some time in Patagonia in 1878-79 and described her travels in a volume entitled *Across Patagonia* (1880). She was a correspondent of the *Morning Post* of London during the Boer War of 1880-81 and was instrumental in the release of Cetewayo and his return to Africa. In her later life she became greatly interested in woman's rights. Among her writings are: *Defense of Zululand* (1882); *In the Land of Misfortune* (1882); *Gloriana* (1893); *Redeemed in Blood* (1890); *Eilabelle, or the Redeemed* (1904).

DIXIE'S LAND, or DIXIE. A term applied to the Southern States. Its derivation is obscure. It is said to have originated in New York, where a certain Dixie owned a large number of slaves. The latter, when obliged to mi-

grate to the South, grew to look upon their old home as a sort of paradise, which they celebrated in their songs. In time the term "Dixie's Land" was transferred to their new homes, and so became a name for the South among the whites as well as the negroes. The term is also popularly connected with Mason and Dixon's Line—the line of division between the free and the slave States—and is said to have been first used of Texas when that State joined the Union.

DIX'ON. A city and the county seat of Lee Co., Ill., 98 miles west of Chicago, on Rock River, and on the Chicago and Northwestern and the Illinois Central railroads (Map: Illinois, C 2). It is the seat of the Northern Illinois Normal School (private), the Rock River Military Academy, and the Rock River Chautauqua, and contains a fine courthouse and public library. It manufactures condensed milk, shoes, plows, wagons, wire cloth, furniture, Portland cement, etc. Dixon, settled in 1836, adopted the commission form of government in 1911. Pop., 1900, 7917; 1910, 7216.

DIXON, AMZI CLARENCE (1854-). An American clergyman, born at Shelby, N. C. He graduated from Wake Forest College (N. C.) in 1875, studied at the Southern Baptist Theological Seminary, and, being ordained to the Baptist ministry in 1876, held until 1883 pastorates at Chapel Hill and Asheville, N. C. Thereafter he filled the pulpits of Immanuel Church, Baltimore (1883-90), the Hanson Place Church, Brooklyn (1890-96), the Ruggles Street Church, Boston (1896-1901), the Moody Church, Chicago (1906-11), and the Metropolitan Tabernacle, London (1911-). His writings include: *Milk and Meat* (1893; new ed., 1913); *Heaven on Earth* (1896); *The Lights and Shadows of American Life* (1903); *The Christian Science Delusion* (1903); *Present-Day Life and Religion* (1905); *Evangelism, Old and New* (1905); *The Young Convert's Problems* (1906); *The Bright Side of Life and Other Sermons* (1914); *The Glories of the Cross and Other Addresses* (1914).

DIXON, CHARLES (1858-). An English ornithologist, born in London. He discovered the St. Kilda wren and a new species in North Africa. He collaborated with Henry Seebohm on his great work on *British Birds*, in the second volume of which he summarized and modified A. R. Wallace's theory of the relation between nests and coloration of birds. Dixon made a special study of bird migration—especially in his book *The Migration of Birds* (new ed., 1897), an ingenious but overtheoretical work—and of geographical distribution of birds. Of his many books the following may be mentioned: *Rural Bird Life* (1880); *Evolution without Natural Selection* (1885); *Our Rarer Birds* (1888); *The Nests and Eggs of British Birds* (1893; illustrated, 1894); *British Sea Birds* (1896); *Lost and Vanishing Birds* (1898); *Game Birds and Wild Fowl of the British Islands* (1899); *Birds' Nests* (1902); *The Bird Life of London* (1909).

DIXON, FRANK HAIGH (1869-). An American economist, born at Winona, Minn. He graduated in 1892 at the University of Michigan, where he remained until 1898, gaining his Ph.D. in 1895 and then teaching history and political economy. In 1898 he was appointed assistant professor, and in 1903 professor, of economics at Dartmouth College; and from 1900 to 1904 he served also as secretary of the Amos

Tuck School of Administration and Finance (Dartmouth). He was expert adviser to the Interstate Commerce Commission (1907-08) and to the National Waterways Commission (1909), and in 1910 became chief statistician to the Bureau of American Railway Economics. Besides contributing to magazines, he published: *State Railroad Control* (1896); *Recent Railroad Commission Legislation* (1905); *A Traffic History of the Mississippi River System* (1909).

DIXON, JAMES MAIN (1856-). An American teacher and author, born at Paisley, Scotland. He graduated at St. Andrews University in 1879 and was appointed scholar and tutor of philosophy there in the same year. He was professor of English and secretary of the Imperial College of Engineering, Tokio, Japan, from 1879 to 1886, when he was called to the Imperial University of Japan in the same capacity. From 1892 to 1901 he was professor of English literature at Washington University, St. Louis, Mo. In 1903-04 he was president of Columbia College, Milton, Oregon. He was professor of English literature at the University of Southern California from 1905 to 1911, when he was transferred to the chair of Oriental studies and comparative literature. In 1906 he became literary editor of the *West Coast Magazine*. He compiled a *Dictionary of Idiomatic English Phrases* (1891) and wrote: *Twentieth Century Life of John Wesley* (1902); "Matthew Arnold," in *Modern Poets and Christian Teaching* (1906); *A Survey of Scottish Literature in the Nineteenth Century* (1907).

DIXON, JOSEPH (1799-1869). An American inventor. He made important improvements in photography, bank-note printing, steel smelting, and lens grinding. He was by turns a shoemaker, printer, lithographer, wood engraver, and physician, and gained wealth from his crucible works, established at Salem, Mass., in 1827 and removed to Jersey City in 1847.

DIXON, JOSEPH MOORE (1867-). An American lawyer and public official, born at Snow Camp, N. C. He was educated at Earlham College (Ind.) and at Guilford College (N. C.). Admitted to the bar in 1892, he took up law practice at Missoula, Mont. He was assistant prosecuting attorney (1893-95), and prosecuting attorney (1895-97), of Missoula County, and a member of the Montana House of Representatives (1900). In 1903-07 he was a member of the United States House of Representatives, serving in 1904 as delegate to the Republican National Convention. From 1907 to 1913 he was United States Senator from Montana.

DIXON, RICHARD WATSON (1833-1900). An English poet, churchman, and historian, born in London, educated at Oxford, and ordained in 1858. He became honorary canon of Carlisle in 1874, vicar of Hayton, in Cumberland, in 1875, and vicar of Warkworth, in Northumberland, in 1883. His poetical works include: *Mano: A Poetical History in Four Books* (1883); *Odes and Eclogues* (1884); *Lyrical Poems* (1886); *The Story of Eudocia and her Brothers* (1888); *Songs and Odes* (1896); *Last Poems* (1905). His best title to fame, however, rests upon the *History of the Church of England from the Abolition of the Roman Jurisdiction* (6 vols., 1877-1900).

DIXON, ROLAND BURRAGE (1875-). An American anthropologist, born at Worcester, Mass. In 1897 he graduated from Harvard University, where he remained as an assistant in

anthropology, taking the degree of Ph.D. in 1900, and then serving as instructor and after 1906 as assistant professor. He was vice president of the American Academy of Arts and Sciences in 1910-11 and president of the American Folk-Lore Society from 1907 to 1909. He is author of *Maidu Myths* (1902); *The Chimariko Indians and Language* (1910); *Maidu Texts* (1912).

DIXON, THOMAS (1864-). An American novelist and playwright. He was born at Shelby, N. C., and graduated from Wake Forest College (North Carolina) in 1883. He served in the North Carolina militia during 1885-86, resigning to enter the Baptist ministry, but soon leaving the pulpit for the lecture platform and for the work of a novelist and dramatist. He wrote: *The Leopard's Spots* (1902); *The One Woman* (1903); *The Clansman* (1905); *The Life Worth Living* (1905); *The Traitor* (1907); *Comrades* (1909); *The Root of Evil* (1911); *The Sins of the Father* (1912); *The Southerner* (1913); *The Victim: A Romance of the Real Jefferson Davis* (1914). In the play, *The Sins of the Father*, which was produced in 1910-11, Dixon himself played the leading role.

DIXON, WILLIAM HEPWORTH (1821-79). An English writer and traveler. He was born in Manchester. Beginning life as a clerk, he decided in 1846 to take up literature as a profession, and, after gaining some journalistic experience at Cheltenham, settled in London. He became a contributor to the *Athenaeum* and the *Daily News*. In 1851 appeared his *Life of William Penn*. Two years later appeared his anonymous pamphlet, *The French in England*. From 1853 to 1869 he was editor of the *Athenaeum*. Among his other writings are: *The Personal History of Lord Bacon, from Unpublished Papers* (1861); *The Holy Lady* (1863); *New America* (1867); *Spiritual Wives* (1868); *Free Russia* (1870); *The Switzers* (1872); *History of Two Queens* (1873-74); *White Conquest* (1875); *British Cyprus* (1879).

DIXON ENTRANCE. A strait on the west coast of North America, separating Prince of Wales Island and others of the archipelago off the south arm of Alaska from Queen Charlotte Island on the south (Map: British Columbia, C 4). It is about 100 miles long, from east to west, and 70 miles wide, and connects the Pacific with Hecate Strait on the east. The line dividing the British possessions in this region from those of the United States passes through this strait near the southern end of Prince of Wales Island. See ALASKA.

DIXWELL, JOHN (1608-89). One of the three judges who condemned Charles I to death. He took an active part in the English Revolution as a colonel in the Parliamentary army and was a member of Parliament for several years. After the accession of Charles II he fled from England to save his life and, under the name of John Davids, lived, married, and died undiscovered in America, for the most part at New Haven, Conn. Consult Stiles, *History of Three of the Judges of Charles I: Whalley, Goffe, and Dixwell* (Hartford, 1794).

DIYALA, dē-yā'la. The most important affluent of the lower Tigris. The point of confluence of the two rivers lies between Bagdad and Ctesiphon. The Diyala takes its source within Persian territory in the Zagros Mountains, where it is known as the Gabe-Rud. South of parallel 35° N. it follows the Turco-

Persian boundary and is called the Shirwan. Once in Turkish territory the name of Diyala is given to it. Its waters have been diverted for irrigation since early historical times.

DIZFUL, dēz-fool' (Pers., Dis Bridge). A town of Persia, the capital and principal mart of the province of Arabistan, situated on the river Dis, about 200 miles west of Ispahan (Map: Persia, C 6). The river is crossed by a handsome bridge of 22 arches, and the town contains 34 mosques, a number of schools, and baths. The chief article of commerce is indigo. Its pens, made of oak, are famous throughout the Orient. The population is estimated at 25,000.

DJAKOVA, jā-kō'vā. See ДЯКОВА.

DJAMILLEH, jā-mē-lā'. An opera by Bizet (q.v.), first produced at Paris, May 22, 1872; in the United States, Feb. 24, 1913 (Boston).

DJEZZAR, jēz'zār (Ar. *jazzār*, butcher, tyrant, from *jazara*, to slaughter) (c.1735-1804). A nickname denoting "butcher," given to Achmet Pasha, who was celebrated for his obstinate defense of Acre against Napoleon. He was born in Bosnia, of Christian parents, but turned Mussulman, entered the service of Ali Bey, with whom he occupied the position of chief assassin, and rose, through murder and treason, from the condition of a slave to the Pashalic of Acre. In 1799 he held Acre against Napoleon for two months and forced him to abandon the siege. Stories are extant of his fiendish cruelty, but they are probably exaggerations. As a ruler and man of affairs, he was exceedingly capable.

DJINN. See JINN.

DJINNESTAN, jin'nē-stān', or JINNESTAN. The mythical land of the Djinn or Jinns (q.v.), the Oriental genii or fairies.

DJOWE, jowf. See JOWE.

DLUGOSZ, dlōō'gōsh, JAN (Lat. LONGINUS) (1415-80). A Polish historian, born at Brzez-nica and educated at the University of Cracow. As the protégé of Bishop Fbygnew of Cracow and of King Casimir of Poland, he was sent on important diplomatic missions to the Pope and also to Hungary, Bohemia, and several other countries. He conducted the education of the King's sons and instituted many pious and charitable endowments for university students. The publication that made him famous is the *Historia Polonica* (12 vols., 1455-80), which comprises a complete history of Poland to the date of publication and is characterized by a spirit of noble patriotism and by indefatigable research. His other works include a pretentious documentary history in 12 vols., written in the style of Livy, and considerable writing on ecclesiastical subjects.

DNIEPER, nē'pēr, Russ. pron. dnyēp'ēr. A river of Russia, the largest in Europe with the exception of the Volga and the Danube (Map: Russia, D 5). It takes its rise in the swamps of the Government of Smolensk, and after leaving that government flows in a southerly direction as far as Kiev. At that city it turns southeast and maintains that direction down to Ekaterinoslav, where it again turns to the south. In this part of the river the banks are rocky and elevated, and the river forms its famous rapids, which can be passed only at full tide and with the assistance of experienced pilots. Below Alexandrovsk the Dnieper assumes a southwesterly course, emptying into the Black Sea below Kherson, where it forms a wide estuary, known as the Dnieper Liman. The total length of the river is over 1400 miles.

It is navigable for nearly its entire length and is of great commercial importance. Its course affords the main artery of commerce for the 14,000,000 inhabitants of its basin. Its chief western tributaries are the Beresina, Pripet, and Ingulets. On the east its waters are swelled by the Soj, Desna, and Psiol. The basin of the river is estimated at 202,000 square miles, almost entirely within the boundaries of Russia. The lowland watered by the river in its lower course is a region of great fertility. It is here that the famous "black soil" of southern Russia is found. This very fertile loam consists of wash transferred from the Dnieper's upper basin. The waters of the Dnieper abound in fish. There is steam navigation from Orsha, in the northern part of the Government of Mohilev, to Ekaterinoslav, and from Alexandrovsk, below the rapids, to Kherson. The freight carried on the Dnieper consists principally of grain and lumber and has an annual value of about \$60,000,000. The Dnieper communicates with the Baltic Sea through the Beresina Canal, which connects the Beresina with the Dvina, the Oginski Canal connecting indirectly the Pripet, a tributary of the Dnieper, with the Niemen, and the Dnieper-Bug Canal, connecting the Pripet with a tributary of the Vistula. In its upper course the Dnieper is usually frozen over from December to April, while at Kherson, near the mouth, it is ice-bound for only two months, from January to March. In ancient times the Dnieper was known as the Boristhenes, or Danapris.

DNIESTER, nē'stēr, Russ. pron. dnyēs'tēr. A river of south Europe, rising in the Carpathian Mountains, near Sambor, in the Austrian Crownland of Galicia (Map: Russia, C 5). It flows in a southeasterly direction through Galicia and enters Russian territory near Khotin, Bessarabia. Its course through Russia, where it separates Bessarabia from Podolia and Kherson, is very tortuous, but has a general southeasterly direction. It empties into the Black Sea between Ovidiopol and Akkerman, forming the Dniester Liman, a shallow sheet of water about 20 miles long and 5 miles wide. The total length of the river exceeds 850 miles, of which over 500 is in Russia. It drains an area of about 30,000 square miles. The Dniester runs mostly through an elevated country. At Yampol rapids formerly interfered with navigation, but they have been partly overcome, and steam navigation begins at Khotin. The chief tributaries of the Dniester are the Stry from the right and the Sereth from the left. The Dniester is rich in fish. Its commercial importance has been much increased owing to improvements introduced by the Russian government. The chief articles of traffic are grain and lumber from Galicia, Podolia, and Bessarabia. In ancient times the Dniester was known as the Tyras, or Danaster.

DOAB, dō-āb' or dōō-āb' (from Pers. *dū*, two + *āb*, water). A word applied, in Hindu countries, like the Greek *mesopotamia* to any region between two rivers. When introduced, however, without local reference of any kind, the Doab means the land inclosed by the Jumna on the southwest and the Ganges on the northeast—a district extending from Allahabad to the base of the Himalayas, a distance of upward of 500, with an average breadth of 55 miles. The fertility of this region has been much increased by the Ganges Canal (q.v.).

DOAK, dōk, SAMUEL (1749-1830). An American Presbyterian clergyman and educator, a

pioneer in the movement for the abolition of slavery. He was born in Augusta Co., Va., graduated at Princeton in 1775, studied theology, and was licensed to preach in 1777. He then ministered to the Holston valley, and later to S. C., Tenn., where he established an academy which grew into Washington College, of which he was president from 1795 to 1818. In 1818 he removed to Bethel, Tenn., where he helped to establish and conduct Tusculum Academy, which in 1844 became Tusculum College. He was generally known as "the Presbyterian Bishop." He early became convinced of the iniquity of slavery, freed his own slaves in 1818, and during the rest of his life, both as a preacher and as a teacher, used the whole of his powerful influence to further the cause of immediate abolition. He is frequently referred to as "the apostle of learning and religion in the West." A sketch of his life is given in vol. iii of Sprague's *Annals of the American Pulpit* (New York, 1857).

DOANE, dōn, GEORGE WASHINGTON (1799-1859). An American bishop of the Protestant Episcopal church. He was born in Trenton, N. J.; graduated at Union College in 1818; studied in the General Theological Seminary, and was ordained a deacon in 1821 and a priest in 1823. He was the assistant of Bishop Hobart in Trinity Church, New York. In 1824-28 he was professor of belles-lettres in Washington (now Trinity) College, Hartford, Conn. He was then successively assistant minister and rector of Trinity Church, Boston, until 1832, when he was elected Bishop of New Jersey. His interest in Christian education soon led him to establish St. Mary's Hall for Girls (1837) and Burlington College (1846), both at Burlington, N. J. He published a volume of poems entitled *Songs by the Way* (1824), besides many familiar hymns, among them "Softly Now the Light of Day." Consult *The Life and Writings of George W. Doane* (4 vols., New York, 1860-61), ed. by his son, Bishop W. C. Doane.

DOANE, WILLIAM CROSBY (1800-1880). An American bishop of the Protestant Episcopal church. He was born in Boston and graduated from Burlington College (N. J.) in 1850. Six years later he was ordained priest by his father, Bishop G. W. Doane, whom he assisted in St. Mary's Church, Burlington. He was rector of St. John's, Hartford, Conn., in 1863-67, and of St. Peter's, Albany, N. Y. In 1869 he was consecrated Bishop of the new diocese of Albany. He organized the cathedral of All Saints in Albany and founded St. Agnes's School for Girls. In 1902 he was chosen chancellor of the regents of the University of the State of New York. He published: a biography of his father (1860-61); *Mosaics, or The Harmony of the Collects; Epistles and Gospels for the Sundays of the Year* (1881); *Rhymes from Time to Time* (1901).

DÖBBELIN, dēb'be-lēn. See **DÖBELIN**, KARL T.

DOB'BIN, MAJOR WILLIAM. An estimable but awkward young officer in Thackeray's *Vanity Fair*.

DOBBS FERRY. A village in Westchester Co., N. Y., 21 miles north of the Grand Central Depot, New York City, on the Hudson River, and on the New York Central and Hudson River Railroad. It is purely a residential suburb of New York and is picturesquely situated at the south end of the broad expansion of the Hudson known as Tappan Bay. The village

has exceptional educational facilities, the Misses Masters School for Girls, the Tupper's Home for Boys and Girls, the New York Juvenile Farm, and a public library; it has also a hospital and playground. Dobbs Ferry's history in connection with the Revolution is interesting. Here, in the old Livingston manor house, Washington and Rochambeau planned the Yorktown campaign; the same mansion is famous for the conference of Washington, Clinton, and Carleton in 1783; and opposite this point was fired the first salute to the American flag by a British sloop of war. Pop., 1900, 2888; 1910, 3455.

DÖBELIN, dē'be-lēn, KARL THEOPHILUS (1727-93). A German actor, born at Königsberg (East Prussia). He studied at Halle and Leipzig and in 1756 established at Erfurt his own dramatic company. From 1758 to 1789 he was a member of several companies and subsequently laid the foundations of the court theatre in Berlin. He did much to promote the presentation of the dramas of Lessing.

DOBELL, SYDNEY THOMPSON (1824-74). An English poet, born at Cranbrook, Kent. His father, who was a wine merchant, removed to Cheltenham in 1836, and Dobell was educated there by private tutors and by himself. In 1844 he married and, owing to his own ill health or his wife's, made many tours abroad, living for three years in Edinburgh and the Highlands, and finally making his home among the Cotswold Hills, where he died. He was a friend of Tennyson, Browning, and Carlyle, of Ruskin and Holman Hunt, and of others of the men best worth knowing of his day. His poems comprise: *The Roman* (1850); *Balder* (1854); *Sonnets on the War*, written in conjunction with Alexander Smith (1855); *England in Time of War* (1856). Dobell belongs to the so-called "spasmodic" school of poets, of whom the extreme type was P. J. Bailey (q.v.). He possessed the true poet's spirit, but was weak in execution. He was a reputable critic and a man of lofty character. Consult: his *Poetical Works*, with a memoir by J. Nichol, published in 2 vols. (London, 1875), the standard edition; *Thoughts on Art, Philosophy, and Religion*, ed. by Nichol (London, 1878); *Life and Letters*, ed. by Jolly (London, 1878). See POETRY, SPASMODIC SCHOOL OF.

DÖBELN, dē'bēln. A town in the Kingdom of Saxony, situated on an island in the river Mulde, 42 miles southeast of Leipzig (Map: Germany, E 3). Among other institutions are a form of pottery, a brewery and an agricultural and manufacturing school. Döbeln is a pretty and thriving place, and has manufactures of woollen yarns, iron, wagons, pianos, cigars, cooperage, sugar, dyes, cloth, leather, and agricultural implements. It has an active trade in cereals. Pop., 1900, 17,745; 1905, 18,900; 1910, 19,627. Consult Markel, *Döbeln und Umgeben* (Döbeln, 1893).

DÖBEREINER, dē'bēr-ī'nēr, JOHANN WOLFGANG (1780-1849). A German chemist, born near Floß (Bavaria). He studied pharmacy at Münchenberg and in 1810 was appointed professor of chemistry and pharmacy at Jena. Goethe and the Grand Duke Karl August of Saxe-Weimar were his friends, and the *Briefe des Grossherzogs Karl August und Goethes an Döbereiner* were published at Weimar in 1856 (ed. by O. Schade). He is best known as the inventor of "Döbereiner's lamp," considerably used previous to the intro-

duction of sulphur matches. In this apparatus a platinum sponge upon which a jet of hydrogen is directed becomes red-hot and ignites the gas. His publications include: *Zur pneumatischen Chemie* (1821-25); *Zur Chemie des Platins* (1836); and other works. Consult Kragenberg, *Die Bedeutung Döbereiners* (Jena, 1862).

DOBLHOFF-DIER, dō'b'l'-hōff-dēr, ANTON, BARON (1800-72). An Austrian statesman. He was a member of the Assembly of Lower Austria and in this capacity revealed himself as a man of decidedly liberal and progressive views. In May, 1848, he was appointed Minister of Commerce and two months later accepted the portfolios of the Interior and of Education. In 1849-58 he was Minister to The Hague. In 1867 he became a life member of the House of Lords.

DOBNER, JOB FELIX (1719-90). A Bohemian historian. At an early age he joined a monastery, his cloister name being GELASIUS A SANTA CATHARINA. He was born at Prague, where he was appointed royal historiographer because of his original researches into the domain of Bohemian history. The Bohemian Society of Sciences erected a monument to his memory. His own works, as well as the numerous treatises published by the society mentioned, still have considerable scientific value. His principal publications are: *Wenceslai Hagek a Liboczan Annales Bohemorum e Bohemica Editione Latine Redditi et Notis Illustrati* (6 vols., 1761-83) and *Monumenta Historica Bohemice nusquam ante hac Edita* (6 vols., 1764-86). For his rare critical acumen and his publication of monumental historical works in his native tongue, Dobner has been called the founder of Bohemian historiography.

DOBREE, PETER PAUL (1782-1825). An English classical scholar, born in the island of Guernsey. He graduated at Trinity College, Cambridge, in 1804, was appointed fellow of Trinity in 1806, and regius professor of Greek in 1823. He devoted himself to the classics and enjoyed the intimate friendship of Porson, whose notes on *Aristophanes* he published in 1820, 12 years after Porson's death, with an edition of the *Plutus*; in 1822 he edited Photius' *Lexicon* after Porson's notes. His own notes on various Greek and Latin authors were published in 1831-33, in 4 vols., under the title *Adversaria*. A small volume containing *Miscellaneous Notes on Inscriptions* was added in 1835. Consult Luard, in *Dictionary of National Biography*, vol. xv (London, 1888), and Sandys, *A History of Classical Scholarship*, vol. iii (Cambridge, 1908).

DOBRICTH, a town of Bulgaria. See BAZARJIK.

DOBROLUBOV, dō-brō-lōō'bōv, NICKOLAI ALEXANDROVITCH (1836-61). A Russian critic of the same school as Belinsky and Chernyshevsky (qq.v.). Born at Nizhni Novgorod, of cultured parents, he learned Krylov's fables when only three years old. At 10 he entered a clerical school, where his brilliant abilities excited the envy of his older classmates. At 17, forbidden by his father (a parish priest) to attend the University, he entered the St. Petersburg Pedagogical Institute. There he continued his remarkable development, failing of a gold medal owing to his participation in certain student activities. At 18, losing both his parents, he had to support not only himself, but all his brothers and sisters. Hard work so

undermined his health that he died of tuberculosis at 25, only four years after his literary career began. His best work, consisting of literary criticism, appeared in the *Contemporary*, a famous Russian periodical. These critical essays fill four large volumes. Dobrolubov was one of the greatest Russian critics. His influence upon Russian thought in the sixties—when Anglo-French utilitarianism was supplanting Hegelian metaphysics—cannot be overestimated.

DOBROVSKÝ, dō-brōv'skē, JOSEF (1753-1829). A Bohemian writer, the "patriarch of Slavonic philology." He was born in Hungary, where his father was stationed in garrison. His education was carried on in German, and he learned his native tongue from his schoolmates when a boy of 10. He studied in Deutschbrod, Klattau, and Prague, and entered the Order of Jesuits, but 10 months later, on its dissolution in 1773, returned to Prague and acquired a solid reputation through his knowledge of Hebrew and his theological scholarship. While tutor in the family of Count Nostitz (1776-87), he had the necessary leisure to devote himself to scientific pursuits and gradually developed into an ardent student of everything connected with the Bohemian nationality, antiquities, language, and literature. In 1780-87 issued several periodicals; dealing with those questions. Appointed subdirector (1787) and then rector (1789) of the General Seminary at Hradisch, near Olmütz, he made many enemies by his outspokenness and fearless criticisms of men prominent in the political and social life of the country. In 1790 the seminary was closed, and Dobrovský retired into private life. Two years later the Royal Bohemian Scientific Society, then recently founded, sent him on a scientific mission. At the society's expense, Dobrovský visited Denmark, Sweden, Finland, and Russia in 1792, and Germany, Switzerland, and Italy in 1794, in search of ancient Bohemian manuscripts and books plundered during the Thirty Years' War. In 1801 he manifested symptoms of insanity. Though he soon recovered from the first attack, the fits of mental aberration kept recurring until his death. When out of his mind, Dobrovský was eager to destroy his works, and it was during one of these fits that he burned the manuscript of the Lusatian Dictionary, which was ready for the press.

Although one of the most brilliant scholars in the period of the revival of Slavonic studies (q.v.), Dobrovský did not believe in the possibility or even desirability of a Bohemian renaissance, his favorite advice to the enthusiasts being, "Leave the dead alone." His interest in the literary remains of the nation did not go beyond scientific investigation. This difference from the point of view of the younger enthusiastic scholars turned into a serious breach when Dobrovský attacked the authenticity of the famous *Judgment of Libusha*, discovered by Hanka in 1817. Jungmann, Hanka, Celakovský, Palacký, and even Safarik bitterly denounced him as a "Slavonizing German," but Dobrovský, though keenly grieved at the animosity of his erstwhile friends, never changed his views. His principal works are: *Scriptores Rerum Bohemicarum* (1783-84); *Geschichte der böhmischen Sprache und ältern Litteratur* (1792; 2d ed., 1818); *Die Bildsamkeit der slavischen Sprache* (1799); *Deutsch-bohmisches Wörterbuch* (1802-21); *Lehrgebaude der böhmischen Sprache*

(1809; 2d ed., 1819), the first scientific exposition of the structure of the Czech language, remarkable for its analysis of the formation of words from roots and for the simplified theory of inflections and consonants and consonants; and *Institutum Linguae Slavicae Dialecti Veteris* (1822), an epoch-making work in its field.

DOBRUDJA, dô-brûd'já, or **DOBROGSA** (anciently *Scythia Minor*). A name applied to the southeastern portion of Rumania (q.v.), bounded by the Danube on the north and west, Bulgaria on the south, and the Black Sea on the east. Its area was formerly about 6000 square miles, but, including the territory added to it by the Treaty of Bucharest of Aug. 10, 1913, is about 9500 square miles (Map: Balkan Peninsula, G 2). Pop., 1880, 147,246; 1899, 267,808; 1905, 297,800, consisting of Rumanians, Tatars, Circassians, Turks, Greeks, Armenians, and Jews. After the Balkan War of 1912-13 its population increased to about 500,000 inhabitants. Before 1878 it belonged to Bulgaria. The Dobrudja is an exceptionally fertile district. Agriculture is the principal occupation of its inhabitants. Cereals, tobacco, beet, vines, and mulberry are the chief agricultural plants raised. For further details, see **RUMANIA**.

DOBSCHÜTZ, dôp'shûts, **ERNST VON** (1870-). A German biblical critic. He was born in Halle; was educated at the universities of Leipzig, Halle, Berlin, and Jena, where he was professor extraordinary in 1899-1904; and then in succession was professor at Bonn (1904-1910), and Halle (1913; exegesis). His most important published works treat the history of the apostolic age; they include: *Kerygma Petri* (1893); *Studien zur Textkritik der Vulgata* (1894); *Die urchristliche Gemeinde* (1902, probably his greatest work; in English, *Christian Life in the Primitive Church*, 1904); *Problème des apostolischen Zeitalters* (1904); *Das apostolische Zeitalter* (1905; in Swedish, French, and English versions), "Thesalonians," in *Meyers Kommentar* (7th ed., 1909); *The Eschatology of the Gospels* (1910); *Das Decretum Gelasianum* (1912); *The Influence of the Bible on Civilization* (1914).

DOBSON. See **CORYDALIS**.

DOBSON, (HENRY) **AUSTIN** (1840-). An English poet and critic. He was born at Plymouth and was educated at Beaumaris, Cornwall, and Strassburg. He intended to adopt the profession of his father, civil engineering, but in 1856 entered the Board of Trade as a clerk, from which he did not retire until 1901. In 1868 he published some poems in Trollope's *St. Paul's Magazine* and soon attracted attention by his skillful and graceful handling of French artificial forms of verse—the rondeau, ballade, and others—and by his delicate satire. George Eliot was among those who early recognized the fine quality of his literary and poetical gifts. In 1902 he received the degree of LL.D. from the University of Edinburgh. Among his volumes of poetry are: *Vignettes in Rhyme* (1873); *Proverbs in Porcelain* (1877); *Old World Idylls* (1883); *At the Sign of the Lyre* (1885). His collected poems first appeared in 1897 (9th ed., 1913). His prose includes: lives of Hogarth (1879; enlarged, 1900), Fielding (1883), Steele (1886), Goldsmith (1888), Richardson (1902), and Fanny

Burney (1903); *Thomas Bewick and his Pupils* (1884); *Memoir of Horace Walpole* (1890); *The Paladin of Philanthropy* (1899); *Eighteenth-Century Vignettes* (3d series, 1892, 1894, 1896); *Sidewalk Studies* (1902); *Old Kensington Palace* (1910); *At Prior Park* (1912). He was also active as an editor, especially of eighteenth-century authors, and notably of Gay, Goldsmith, Steele, Richardson, and Madame D'Arblay—the *Diary*. All his work, including a large number of contributions to the more important magazines and reviews, to encyclopedias, and to the *Dictionary of National Biography*, is marked by scholarship, an exacting taste, and literary finish, grace, and charm.

DOBSON, **WILLIAM** (1610-46). An English portrait painter. He was born in London and studied under the engraver Robert Peake and the German painter Franz Cleyn; but his principal artistic training was gained as assistant to Van Dyke, who strongly influenced his art. He was presented to Charles I by Van Dyke, and after the latter's death was appointed court painter. Dobson painted portraits of the King, the Prince of Wales (Windsor Castle), and members of the royal family and the court, including the Earl of Essex (Knole Park), Lord and Lady Fairfax (National Portrait Gallery, London), and Endymion Porter (National Gallery), one of his finest achievements. The color and brushwork of his last period, which began after 1640, show also the influence of Tintoretto, for which reason he was called the "English Tintoretto" by Charles I. Dobson's extravagance resulted in his imprisonment for debt under the *Proclamation*, shortly before his death. Many of his portraits are in English private collections; others are at Windsor Castle, Hampton Court, and in the National Portrait Gallery. His few historical and religious pictures are of less importance.

DOCEN, dô'tsen, **BERNHARD JOSEPH** (1782-1828). A German philologist, born at Osnabrück. He studied at Göttingen, where he was a pupil of Heyne, and at Jena, and from 1804 was connected with the State library at Munich, of which he was, in 1811, appointed custodian. His reputation is based largely on the critical examination of the Old and Middle High German manuscripts, which were deposited at Munich in consequence of the secularization of the cloisters in Bavaria. He was the first to call attention to the importance, in the study of the history of the German language, of the short fragments of early prose, the first Latin-German dictionaries, and the German glosses to Latin manuscripts of the period from the eighth to the twelfth century. He was one of the editors of the *Museum für altdutsche Literatur und Kunst* (2 vols., Berlin, 1809-11). Among his publications may be cited the *Ussellaneen zur Geschichte der deutschen Literatur und Kunst* (2 vols., Munich, 1807-09).

DOCENT, dô-tsént' (Lat. *docere*, 'to teach'). A teacher in German universities, with full official relations. In its more general sense the term includes professors of all grades and the privatdocent (q.v.). In American universities it indicates a member of the teaching staff of the lowest grade. In Clark University (q.v.) it is a distinction bestowed annually upon those "whose work has already marked a distinct advance beyond the doctorate and who wish to engage in research." The appointee is expected to deliver some lectures, may receive a salary,

and may be "formally invested with the *licentia docendi* . . . the highest formal academic honor." in the University of Chicago (see CHICAGO, UNIVERSITY OF), *docent* is a rank just above that of fellow. See UNIVERSITY.

DOCE'TÆ (Lat., from Gk. *δοκῆται*, *Dokētai*, from *δοkein*, *dokein*, to seem). The name given in the early Church to those who held that the material body and human nature of Jesus Christ were a semblance and not a reality. Gnosticism could not conceive the real union of the divine nature with a body composed of matter, which they held to be the seat of all evil. When some Gnostics became Christian, they met the difficulty in one of three ways: the body of Christ was either considered a real earthly body, but not belonging essentially to His nature and only assumed for a time; or it was declared to be a mere appearance or illusion; or, finally, it was believed to be a heavenly body, composed of ethereal substance, though having the appearance of being material. Most Gnostic Christians held Docetism in one or other of these three forms, though some denied the divine nature of Jesus Christ and reduced him to a mere human sage. Later, Docetism appeared in other sects, as the Manichæans (q.v.), and even Clement of Alexandria and other Church fathers have been charged with this tendency. Consult the *Histories of Doctrine*, by Fisher (New York, 1896), and Harnack (trans. by Buchanan, Boston, 1894-1900). See GNOSTICISM.

only in the water in which the ship floats, but that body of water becomes a dock only by virtue of the walls which more or less completely surround it, the gates (in the case of the wet dock) which maintain it on even level, and the warehouses, service railways, and freight-handling machinery which line its sides.

Wet docks are common to the ports of England, France, South America, and the Orient at places where the tide ranges are higher than 10 feet. A few of the large ports so equipped are London, Liverpool, Cardiff, Aberdeen, Dublin, Swansea, and Dunkirk, in Great Britain; Havre, Marseilles, Rouen, and St. Nazaire, in France; Hamburg and Kiel, in Germany; Calcutta, in India; Cape Town, in South Africa; Antwerp, in Belgium; Buenos Aires, in Argentina, and Hongkong, in China.

The wet dock is normally an extensive basin walled off from the tidal sea by a lock chamber and a swinging gate similar to those used in canal locks (see CANAL), or more rarely by a specially shaped caisson gate which is floated into place. It is provided with a number of piers, quays, or wharfs at which vessels may be moored. On account of variation in design, due primarily to geographic and topographic conditions, the different docks of the world cannot be classified into types and described as such; so a description is given below of one London wet dock, which will exemplify the general principles of their design.

ROYAL ALBERT AND VICTORIA DOCKS, LONDON, ENGLAND.

DOCK (Ger. *Dock*, of uncertain origin). Any space or structure in or upon which a ship may be berthed or held for loading, unloading, repairing, or safe-keeping. Docks are of two kinds—wet docks, with the subclass of tidal locks; and dry docks, with the subclass of floating docks. A wet dock is a basin surrounded by quays, the entrance to which is closed by a gate and in which the water level is constantly at the same height; they are employed where the range of tide is considerable, such as at Liverpool with 30-foot difference in tide level. A tidal dock is a similar basin open to the harbor waters, in which the water level fluctuates with the rise and fall of the tides; they are employed where the tide variation is so low as not to cause serious inconvenience to vessels moored in the dock.

Wet Docks. The wet dock and the tidal dock, more commonly known by the general term "dock," are primarily for the purpose of berthing vessels for loading and unloading and are a part of the great port systems in the service of commerce. Fundamentally the dock consists

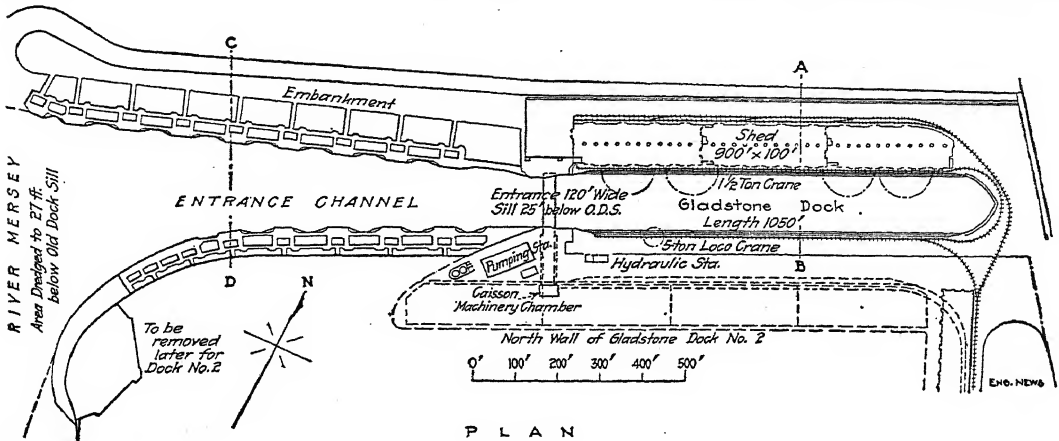

The Royal Albert and Victoria docks at London (see figure) are excavated across a neck of land formed by a bend in the river Thames and thus have two entrances, one at each end. Beginning at one end, there is a dock 350 feet long and 80 feet wide, which opens into a basin that is separated by a gate from the Royal Albert Dock. This dock is 6500 feet long and 490 feet wide and has an area of 84 acres. A channel 80 feet wide connects the Royal Albert Dock with the Royal Victoria Dock. This dock is 1050 feet wide and has a series of jetties or piers on one side to increase the amount of quay space; the total area is 74 acres. The Royal Victoria Dock opens into a tidal basin 16 acres in area, which in turn opens into the Thames by means of a canal and lock. The depth of water in the Albert Dock is 30 feet and in the Victoria Dock 28 feet.

Only one wet dock with gates exists in the United States; that is at the port of Seattle, Washington, and is now in course of construction. The lock is a double structure, comprising a large chamber for heavy shipping, log

rafts, etc., and a small chamber for the use of small boats. The larger lock will be 825 feet long and 80 feet wide and will have a maximum

sound and are located at the outlet of Salmon Bay, 1 mile inland from deep water.

Tidal Docks are adapted to locations where

England coast to about 2 feet at Galveston, Tex., at the Mediterranean ports, at Glasgow, Scotland, and Hamburg, Germany. The almost universal form of dock in America is a series

of rectangular water spaces between piers which project out from the bulkhead line, although tidal-basin docks are found in a few places. The Atlantic Docks and the Erie Basin in Brooklyn are examples. The Atlantic Docks were commenced in 1841 and were several years in construction. More than 200 acres of land were secured by the Atlantic Dock Company, and 40 acres of low marshland were converted into a basin. Excavation over the whole 40 acres was done mainly with dredges and was carried to a depth of 20 feet below low-water mark. The outer inclosure was made with piers of cribwork, consisting of timber filled with stone, which were sunk into trenches 30 feet below high-water mark. The cribs were 25 feet thick at the base and were placed 150 feet apart, that being the width of the pier. In the basin are a number of wooden piers where vessels are loaded. Upon the cribwork piers large stone warehouses are built. On the inland side is the commercial wharf, 2000 feet in length. The

CROSS SECTION OF LEVIS DRY DOCK, CANADA.

Erie Basin, near the Atlantic Dock, contains two graving docks.

A **Dry Dock** is a masonry or timber-lined basin connecting with the harbor waters and having approximately the shape of a ship's hull, into which a vessel can be floated and which can then be closed and emptied so as to leave the vessel propped up on struts and blocks with the bottom dry and available for cleaning and repairs. When the vessel is floated into the dock and the water removed, either by natural or artificial means, it is called a graving dock, while, when the vessel is partially removed from the water by means of ways, and the rest of

Material. Before the advent of Portland cement concrete most docks were built of rough stone faced with cut granite. In France and England particularly the old docks are very excellent examples of masonry and show well coursed and bonded faces. Some of the earlier docks were built with rough stone with granite quoins and copings only. With the introduction of Portland cement concrete took the place of the rough stone backing in England, while in France the cheapness of labor, together probably with adherence to precedent, has caused the retention to this day of hand-laid rubble mass work. In Germany concrete was adopted for the mass work of docks built towards the end of the last century. It is only in the latest and largest works in Europe that concrete surfaces appear. In the United States the original material used in dock construction

was timber, except in the case of some of the earlier dry docks of granite in the United States navy yards, but with the advent of concrete it has been largely applied to dry-dock construction. As noted above, there are practically no wet docks in the United States.

of five pontoons or water-tight boxes. Three of these compose the bottom of the dock, while two form the side walls. These pontoons are divided by means of partitions into 40 water-tight compartments, and each has an inlet for the admission of sea water and an outlet connected

THE DRY DOCK AT LEVIS ON THE ST. LAWRENCE RIVER OPPOSITE QUEBEC. UNDER CONSTRUCTION, 1914.

Floating Dry Docks have been built in considerable numbers in both Europe and America, the majority of them being for vessels of from 2000 to 4000 tons. They are of steel or iron frame and plate construction, in design similar

by piping with steam pumps for expelling the water. The vessel is floated in and carefully centred over the keel blocks, and the pumps are then set to work to remove the water from the compartments. As the dock raises the vessel

to ships. The latest and largest floating docks are given in the accompanying table.

SECTION OF THE ALGIERS FLOATING DRY DOCK.

The New Orleans (Algiers) Dock, shown here with holding a 15,000-ton battleship, consists

out of the water, shores are inserted between the vessel's hull and the side walls, and the pumping is continued until the floor of the dock

is raised above the water level. The Philippine Island dry dock, *Dewey*, was constructed at Sparrows Point, Md., in 1905 and towed to the Philippines. It is in three sections, so as to be self-docking. If the central section, which is 316 feet long, is to be docked, the two end sections are detached, placed beneath it and exhausted of water, while if the end sections are to be docked they are placed in the mid-section as a vessel would be, and it is pumped free of water. The dock is operated by steam.

Consult: Colson, *Notes on Dock Construction* (London, 1894); Stevenson, *Design and Construction of Harbors* (ib., 1886); Cunningham, *Principles and Practice of Dock Engineering* (2d ed., ib., 1910); Cardemoy, *Les ports modernes* (Paris, 1900); Staniford, *Report on the Physical Characteristics of European Seaports* (New York, 1911). Consult also the proceedings of the various engineering societies and the engineering journals.

DOCK (AS. *docce*, probably connected with Gael. *dogha*, burdock). A name applied to those species of the section *Lapathum*, of the genus *Rumex*, which are not acid or only slightly so, and of which the flowers are perfect or polygamous. The other species are generally called sorrel (q.v.). The docks are mostly large, perennial, herbaceous plants, natives chiefly of temperate climates, with large, generally lanceolate or ovate leaves, and panicles of small greenish flowers. They multiply rapidly by seed, have great taproots, and are with difficulty eradicated from pastures. The best mode of dealing with them is generally found to be repeated cutting away of the leaves and shoots, by which the plants are killed. Many of the species prefer watery places. A number are natives of the British Isles, and several of the European species have been introduced into North America, where also a number of indigenous species are found and have been troublesome weeds. Useless and even troublesome as the docks are generally esteemed, the large, astringent roots are yet capable of being beneficially employed in medicine; and those of the greater water dock (*Rumex britannica*), in particular, for which the Druids entertained a superstitious veneration, are administered as an antiscorbutic, astringent, and tonic. Those of *Rumex crispus*, the yellow dock, are used in the same manner. The roots contain variable quantities of tannin, and the occurrence of this in large quantities in canaigre (*Rumex hymenosepalus*) (q.v.) has been made use of in tanning fine grades of leather. The young leaves of a number of species are often used as potherbs.

A large variety of this plant previously unknown to the Indians was introduced by the white settlers and followed their westward advance so persistently that it was named by the Indians of the west "the white-man's foot."

DOCK, LAVINIA L. (1858-). An American writer on nursing, born in Harrisburg, Pa. She graduated from the Bellevue Hospital Training School in 1886. She served in the Johns Hopkins Hospital, Baltimore (1890-93), Cook County Hospital, Chicago (1893-96), and also in a yellow-fever epidemic at Jacksonville, Fla., and at the Johnstown (Pa.) Flood. In 1898 she became a resident member of the Nurses' Henry Street Settlement in New York City. She was elected secretary of the American Federation of Nurses and of the International Council of Nurses. Her writings include: *Text-*

Book of Materia Medica for Nurses (1889; 4th ed., 1905); *History of Nursing* (1907; vols. iii, iv, 1912), with M. Adelaide Nutting; *Hygiene and Morality* (1910).

DOCKET (also, obsolete or rare forms, *doquet*, *doquet*, *dogget*; probably a diminutive noun from *dock*, to shorten, from *dock*, Icel. *dokr*, stumpy tail). In law, an official record of judicial proceedings. Originally the term was used to denote a brief summary of the contents of a document upon which it was indorsed. It is probable that these memoranda in time came to be transcribed in a book to which the name of docket was then applied. This was particularly the case with records of judgments, and in the United States a register of money judgments is called a docket. Under statutes giving judgments the force of liens on the real estate of the judgment debtor, it is not the rendering or the "entry" of the judgment, but its docketing, which gives it that effect.

But the principal use of the word "docket" in the United States is as the name of a list of causes before the court for trial, entered in the order in which the case is to be called, in a book kept by the clerk of the court. Such a docket is called by the practice of some courts the calendar. The docket, or calendar, is usually called over at the opening of the court each day in order to ascertain what cases are ready for trial and to determine the order in which they shall be heard. The term "docket" is also employed in England to designate a copy of a chancery decree left with the proper clerk of the court for enrollment.

DOCK WARRANT. A written instrument, in the nature of a warehouse receipt, given by a dock owner to the consignor of goods therein described, acknowledging their receipt and engaging to deliver them to the owner or to his assignee. It differs from a bill of lading at common law in that it is not, like the latter, a symbol of the goods for which it is given, and its assignment and delivery, even to a purchaser of the goods for value, does not have the legal effect of a delivery of the goods themselves. The reasons assigned for this difference are two: 1. A bill of lading is an ancient mercantile document governed by the rules of the law merchant, while a dock warrant is modern and controlled by common-law principles. 2. A bill of lading is the representative of goods which are at sea or in the possession of a common carrier on land. One who transfers this document does all that is possible for him to give possession of the goods to the purchaser. On the other hand, it is always possible for parties to a sale and purchase of goods in a dock owner's possession to make an actual transfer of that possession.

The foregoing doctrine of the common law has been changed by the Factors Act in England, which puts dock warrants on the same footing with bills of lading. As a species of warehouse receipts, they are declared by statute to be negotiable in many of our States.

DOCTOR (Lat., from *docere*, to teach). A title formerly used, in accordance with its deri-

vation, to signify a teacher in general; in more recent times it is a title of honor conferred by universities. The word had long been used as a general term for teacher, before it came to designate degree or rank in the learned hierarchy, to which only the united body could advance the candidate. In this sense it seems to have been first used at Bologna about the middle of the twelfth century—not earlier, as it is never found applied to the learned Irnerius, the regenerator of the Roman law at that period, who called himself *judex*, and was called by others *magister*, *dominus*, or *causidicus*. The first to bear it were the so-called “four doctors”—Bulgarus, Martinus, Jacobus, and Hugo. When it began to be formally bestowed, it conferred the unrestricted right to teach, and a voice in the granting of degrees to others. Originally confined to teachers of civil law, by the end of the century it was also applied to canonists; a decretal of Innocent III proves the existence of *doctores decretorum* as well as of *doctores legum*. This distinction between the two branches of the law has left a trace even to the present day in the degree granted by some universities in Germany and America of J.U.D., *juris utriusque doctor*, ‘doctor of both laws,’ and in the more familiar LL.D., where the double L stands for the plural *legum*. In the thirteenth century doctors of medicine, grammar, logic, and philosophy are found; the jurists, however, seem to have attempted to limit the use of the title to themselves, leaving that of *magister* to the theologians and others. The University of Paris almost immediately followed in the footsteps of Bologna, the first bestowment of doctors having taken place in the year 1145, in favor of Peter Lombard and Gilbert de la Porée, the greatest theologians of the day. The emperors were accustomed to grant the universities the right of appointing doctors of law by their authority and in their name; in the same way the popes conferred the right in regard to canon law. Throughout the Middle Ages, however, there was a tendency to use indiscriminately the titles of master, doctor, and professor. In the University of Paris, and others which closely imitated it, the term “master” was commonly used in the faculties of medicine, theology, and arts; but the title of professor is frequently, and that of doctor occasionally, employed. At first the same confusion existed at Oxford, but during the fifteenth century the custom gradually prevailed in the English universities of limiting the use of the title “doctor” to the faculties of law, theology, and medicine. In Germany the title was known as early as the thirteenth century and for a long time very highly regarded; doctors were recognized, even by the Imperial law, as entitled to the privileges of nobility. But when the degree began to be carelessly conferred, they sank in the public estimation, until it was possible for a proclamation in Hesse-Cassel, 1762, to put them in the tenth class, with valets and the like. In France, also, while up to the Revolution the highest consideration attached to the title of Doctor of the Sorbonne (q.v.), that famous theological faculty which was called “the perpetual council of the Gallican church,” such was by no means the case with the degrees of the other schools of learning. Furetière, in his dictionary, defines a scholar as a man who learns, and a doctor as a man who forgets. In England the doctor’s degree was not introduced

into the universities till the reign of John or Henry III. For a time it was a very rare and highly prized honor, and the ceremony of conferring it was attended with scenes of feasting and revelry, of which curious accounts will be found in Anthony a Wood, *History and Antiquities of the University of Oxford* (London, 1792–96). In modern times the title of doctor has been applied almost everywhere to the three faculties of theology, law, and medicine. In America and Germany it extends to that of philosophy, and in the latter country the degree of “doctor of philosophy and master of arts” is conferred, as if the two were equivalent. Oxford and Cambridge, and in modern times some of the German and American universities, also create doctors of music. The doctor’s degree is, in general, conferred at the instance of the dean of the faculty to which it appertains. It is granted on examination, or after at least the ancient form of publicly defending a learned thesis in Latin has been observed; or else it is an honorary degree, conferred in consideration of the general reputation of the recipient for eminence in some particular branch of learning, or occasionally on account of some other distinction. The musical degree in the English universities, which is equivalent to the master’s degree in other faculties, there being no degree of master of music, is given only after approval of a cantata composed by the candidate and performed at his expense. Consult: Rashdall, *Universities of Europe in the Middle Ages* (Oxford, 1895); Denifle, *Die Universitäten des Mittelalters bis 1400* (Berlin, 1885); and the authorities referred to under UNIVERSITY and DEGREE. For professional uses of the degree of D.C.L., see DOCTORS’ COMMONS.

DOCTOR, THE. A romance by Robert Southey, first issued anonymously (1834).

DOCTOR AND STUDENT. The title of a celebrated little book on the common law, which made its appearance in the reign of Henry VIII, probably about 1530. It is attributed to one Christopher Saint-Germain, a barrister of the Inner Temple, about whom nothing definite is known. The work was originally composed in Latin and is cast in the form of a dialogue between a doctor of divinity and a very learned “student” of the common law, the latter instructing the former in a somewhat didactic manner in the mysteries of his system. It contains some suggestive discussion of legal principles, common-law doctrine being sometimes effectively contrasted with the doctrine of the civil law, usually to the advantage of the latter. The book contrasts the doctrine of consideration in contracts, which was then beginning to take form in the English legal system, with the Roman law doctrine of *causa* and throws a good deal of light upon the former. The work is a mere fragment, however, and though it has enjoyed a considerable reputation it never rose to the rank of a legal authority. It appears to have taken on its present English form in the lifetime of the author, being, perhaps, translated by his own hand. It has passed through many editions, the best being the eighteenth, by Muchall, published in Dublin in 1792, and republished in Cincinnati in 1874.

DOCTOR FISH. See SURGEON FISH.

DOCTOR JEKYLL. See STRANGE CASE OF DR. JEKYLL AND MR. HYDE.

DOCTORS’ COMMONS. A name applied both to the association of doctors of the civil

and canon law in London, practicing by exclusive privilege in the ecclesiastical courts, and to a building erected by them about 1567 near St. Paul's for the accommodation of those courts and the Court of Admiralty. The doctors were divided into two classes—advocates and proctors—corresponding to attorneys and solicitors, and were headed by a president, the dean of arches for the time being. Admission to practice was granted to a D.C.L. of Cambridge or of Oxford by the decree of the archbishop, after an elaborate ceremony. The college was dissolved in 1857 and the property sold, the proctors being given privileges of solicitors and receiving compensation, and solicitors being allowed to act as proctors. The principal ecclesiastical court comprised in the Doctors' Commons was the Court of Arches, the appellate court of the Archbishop of Canterbury, presided over by the dean of arches, with original jurisdiction in all ecclesiastical cases in the Province of Canterbury, and also in cases raised by letters of request. (See LETTER.) Divorces were formerly tried here, but are now tried by the Divorce Court. The other courts have in the main suffered the same fate. They comprised the Archdeacon's Court, for ecclesiastical cases in the archdeaconry; the Prerogative Court, with certain probate jurisdiction (now transferred to the Probate Court); the Faculty Court, for the granting of dispensations; and the Court of Delegates, in cases of ecclesiastical appeals (now transferred to the judicial committee of the Privy Council). The buildings as well as the organization of the Doctors' Commons have disappeared, the courts have been amalgamated with others, the officials have lost their special privilege, but the old names remain, and will probably die out but slowly. For the statutes of the changes in the old arrangement, see 21 Vict., c. 77; 21 and 22 Vict., cc. 95, 108; 23 and 24 Vict., c. 27; 33 and 34 Vict., c. 28, s. 30; 40 and 41 Vict., c. 25, s. 17. Consult also Stow, *Survey of London* (London, 1598). See ARCHES, COURT OF; ATTORNEY; BARRISTER; SOLICITOR.

DOCTORS OF THE CHURCH. A title long current for the most eminent of the early Christian teachers, and applied especially to the four Greek fathers—Athanasius, Basil, Gregory Nazianzen, and Chrysostom—and the four Latin fathers—Ambrose, and Gregory. In recent times the title has been formally conferred by the Pope on saints eminent for theological learning, some as modern as St. Alphonsus Liguori (died 1787). In the Middle Ages the name of doctor was freely applied to the leading theologians, with some additional expression characterizing the peculiar gift of the writer designated.

The following alphabetical list of such affixes is taken from Wetzer and Welte, *Kirchenlexikon*, 2d ed. by Kaulen (Freiburg, 1882-1900). The date is that of death, and the contractions are as follows:

O.Carm.	= Carmelite	O. Præm.	= Præmonstratensian.
O.Carth.	= Carthusian.	O.S.A.	= Augustinian.
O.Cist.	= Cistercian.	O.S.E.	= Benedictine.
O.M.	= Minorite or Franciscan.	O.Trin.	= Trinitarian.
O.P.	= Dominican.	S.J.	= Jesuit.

Doctor abstractionum, acutus et illuminatissimus—Francis of Mayroni, 1325 or 1327.
—acutissimus—Francis della Rovere (Pope Sixtus IV), 1484.

Doctor abstractionum, acutus—Gabriel Vasquez, S.J., 1604.
—admirabilis (mirabilis)—Roger Bacon, O.M., 1294.
—amēnus—Robert of Cownton, O.M., about 1340.
—angelicus, communis, or cherubicus—St. Thomas Aquinas, O.P., 1274.
—authenticus—Gregory of Rimini, O.S.A., 1358.
—authoratus, copiosus, fundatissimus et solidus—Richard of Middleton, O.M., about 1300.
—beatus et fundatissimus—Giles Colonna, O.S.A., 1316.
—bonus—Walter Brinkelius, O.M., about 1310.
—Christianissimus—John Charlier of Gerson, 1429.
—Christianus—Nicholas of Cusa, 1464.
—clarus—Louis de Montesinos, 1621.
—clarus et subtilis—Dionysius junior, O.Cist., fifteenth century.
—collectivus—Landolfo Caracciolo, O.M., 1351.
—columna doctorum—William of Champeaux, O.S.B., 1121.
—communis—St. Thomas Aquinas, O.P., 1274.
—conspicuus et planus—Walter Burley, after 1337.
—contradictionum—John Wessel, 1489.
—divinus, ecstasticus—John of Ruysbroeck, 1381.
—doctorum—Anselm of Laon, 1117.
—dulcifluus—Antony Andrea, O.M., about 1320.
—ecclesiæ—St. Thomas Aquinas, O.P., 1274.
—ecstasticus—Dionysius of Rickel, O.Carth., 1471.
—elegans et facundus—Peter Aureoli, O.M., 1322.
—eminens—St. John of Matha, O.Trin., 1213.
—excellentissimus—Antony Corsetti, 1503.
—eximius—John Tisserius, O.M., about 1564, and Francis Suarez, S.J., 1617.
—famosissimus—Peter Alberti, O.S.B., about 1426.
—famosus—Bertrand de la Tour, O.M., 1334.
—fundamentalis, subtilis et perspicacissimus—John Faber of Bordeaux, about 1350.
—fundatus—William Verus (de Waria), O.M., about 1270.
—illibatus—Alexander Alamannicus, O.M., fifteenth century.
—illuminatus—Raymund Lulli, O.M., 1315.
—illuminatus et sublimis—John Tauler, O.P., 1361.
—illustratus—Francis Picenus, O.M., fourteenth century.
—illustris or illustratus—Adam of Marisco, O.M., about 1380.
—inclytus—William Mackelfield, O.P., about 1300.
—ingeniosissimus—Andrew of Neufchâteau, O.M., about 1300.
—invincibilis—Peter Thomas, O.M., fourteenth century (?).
—invincibilis et singularis—William of Occam, O.M., 1349.
—irrefragabilis, fons vitæ, monarcha theologorum—Alexander of Hales, O.M., 1245.
—magnus—Albertus—O.P., 1280.
—magnus, universalis—Alan of Ryssel, O.Cist., 1202.
—marianus—St. Anselm of Canterbury, 1109, and John Duns Scotus, O.M., 1308.
—mellifluus—St. Bernard, O.Cist., 1153.
—mellifluus alter—Ælred, O.Cist., 1166.
—mirabilis—Antony Perez, S.J., 1649, and Roger Bacon, O.M.
—moralis—Gerhard Eudo, O.M., 1349.
—notabilis—Peter of Ryssel, O.M.

- Doctor abstractionum, ordinatissimus or ornatissimus—John of Bassoli, O.M., about 1347.
 —ornatissimus et sufficiens—Peter of Aquila, O.M., about 1344.
 —pacificus et proficius (profitabilis)—Nicholas Bonet, O.M., 1360.
 —planus et utilis—Nicholas of Lyra, O.M., 1341.
 —præclarus—Peter of Kaiserslautern, O.Prem., about 1330.
 —præstantissimus—Thomas Netter of Walden, O.Carm., 1431.
 —profundissimus—Paul of Venice, O.S.A., 1428; Gabriel Biel, 1495; John Alphonsus Curiel, O.S.B., 1609.
 —profundus—Thomas of Bradwardine, 1349.
 —refulgidus—Peter Philargi (Pope Alexander V), 1410.
 —resolutissimus—William Durand of Saint-Pourçain, O.P., 1332.
 —resolutus, princeps Averroistarum—John Bacon, O.Carm., 1346.
 —scholasticus—Peter Abélard, 1142; Gilbert de la Porrée, 1154; Peter Lombard, 1164; Peter of Poitiers, 1205; and Hugh of Castro Novo, O.M., after 1322.
 —seraphicus—St. Bonaventura, O.M., 1274; sometimes also St. Francis of Assisi, O.M., 1226.
 —solemnis—Henry Goethals of Ghent, 1293.
 —speculativus—James of Viterbo, O.S.A., 1308.
 —sublimis—Francis of Bachepe, O.Carm., 1372, and John Courtecuisse, about 1425.
 —subtilis—John Duns Scotus, O.M., 1308.
 —subtilissimus—Peter of Mantua, fourteenth century (?).
 —succinctus—Francis of Ascoli, O.M., about 1340.
 —summus doctorum—Peter of Belle-Perche, 1308.
 —universalis—Albert the Great, O.M., 1280.
 —venerandus—Walfried de Fontibus, O.M., after 1240.

DOCTOR'S TALE, THE. A story contained in Chaucer's *Canterbury Tales*, supposed to be narrated by a doctor of physic, and consisting of an English version of the Roman legend concerning Appius and Virginia, as recounted in the *Roman de la Rose*.

DOCTOR SYNTAX: See COMBE, WILLIAM.

DOCTRINAIRE, dôk'trè'nâr' (Fr., theorist, from Lat. *doctrina*, doctrine). A term used to designate one who is an advocate of principles and of practical schemes in government and politics. After the first restoration of the Bourbons, in 1815, the term came to be applied in France to a portion of the parliamentary opposition which urged the adoption of a plan of government somewhat similar to the English system of a limited monarchy with parliamentary control. For these views they were ridiculed by Republicans and Monarchists and called *doctrinaires*. Mounier, Lally-Tollendal, Clermont-Tonnerre, Talleyrand, and the Abbé Montesquieu were the true fathers of the party. They had their rallying point in the salons of the Duc de Broglie, and were led in the Chamber by Royer-Collard and supported in the press by Guizot, Villemain, Barante, and the younger members of what afterward became the Orleans party. The development of the constitution on the basis of the *charte* of Louis XVIII was their watchword, but their real inspiration was derived from England. When the revolution of 1830 occurred, they became the advisers and ministers of Louis-Philippe, and were more deeply

imbued with the principles of constitutional monarchy than any other political party that has ever existed in France. The revolution of 1848 did away with the doctrinaires as a political party exerting an influence on the government, and the term ceased to be used save historically or in an abstract sense. Consult: Thureau-Dangin, *Le parti libéral sous la Restauration* (Paris, 1876), and the memoirs of Guizot (2 vols., ib., 1858-68), Barante (ib., 1890), and Duc de Broglie (ib., 1886). There is an English translation of Guizot's *Mémoires*, under the title of *Memoirs to Illustrate the History of my Own Time* (4 vols., London, 1858).

DOCTRINE. See DOGMA.

DOCTRINE, FATHERS OF CHRISTIAN, or DOCTRINARIANS. A clerical brotherhood in the Roman Catholic church. It was founded by César de Bus (1544-1607), who after a military career, turning to piety, was ordained in 1582 and became zealous in all good works. Devoting himself especially to opposing the progress of the Huguenots in France in 1592, he joined with Romillon, a canon of Isle, who was a convert from Calvinism, Pinelli, a canon of Vigevano, and two others to form a congregation of secular priests for the purpose of teaching Christian doctrine to the ignorant. It was confirmed by Clement VIII in 1597, and the founder, resigning his canonry, became its first superior. He left a reputation for great sanctity and was declared venerable by Pius VII in 1821. His successor, Father Vignier, after founding several daughter houses, sought to make the brotherhood a regular congregation with solemn vows. Pope Paul V gave his approval on condition that they should unite with some existing congregation. In 1616, accordingly, the congregation joined with the Italian congregation of Somasco, founded by St. Jerome Emiliani; but a few members, not feeling bound to make the solemn vows, joined the French Oratorians. The connection was dissolved by Innocent X in 1647, and Alexander VII allowed the *Doctrinaires* (as they are called in France) to make the simple vows, with the addition of that of perseverance. Under the new system they spread into Italy. After great difficulties from the French Revolution, and internal dissensions which ended in Pius VII's suppression in 1805 against any vows for the future, they have since then proved themselves useful in the nineteenth century, especially in schools and diocesan seminaries, and at the present time have about 600 members. De Bus also founded an order for women, called Daughters of Christian Doctrine, which later became the French Ursulines.

DÓCZI, dô'tsé, LUDWIG VON (1845-). An Hungarian publicist and author, born at Odenburg. He was educated in Vienna and Budapest, was for a time a journalist, in 1867 became an official in the Austro-Hungarian Ministry of the Interior, and later a counselor in that of Foreign Affairs. His publications include the dramas *Utolsó próféta* (1868) and *A Csók*, 'The Kiss' (1871), several works in pro-c. fiction, and poems. He also made some translations into Hungarian, in particular of the first part of Goethe's *Faust* (new ed., 1878) and of Schiller's poems (1903-05).

DOD, DANIEL (1788-1823). An American mechanic, born in Virginia. He was educated at Rutgers College and became one of the most successful engine-builders in the United States.

He constructed the engine for the *Savannah*, the first steamer that ever crossed the Atlantic. He was killed by a boiler explosion at New York City.

DODD, FRANK HOWARD (1844-). An American publisher, son of Moses Woodruff Dodd. He was born at Bloomfield, N. J. In 1870, with Edward S. Mead, he succeeded to the business of his father, under the firm name of Dodd and Mead, the establishment becoming, with the admission of Bleecker Van Wagenen in 1876, Dodd, Mead and Company. Afterward he became the active head of the firm and was instrumental in establishing the *Bookman* in 1895, the *NEW INTERNATIONAL ENCYCLOPÆDIA* (1902; 2d ed., 1914-15), and other important enterprises. He was elected a vice president of the American Publishers' Association. As book-sellers, the firm became one of the leading authorities upon and dealers in rare books. It has published the works of many distinguished writers in all branches of literature.

DODD, MOSES WOODRUFF (1813-99). An American publisher, born at Bloomfield, N. J. After graduation at Princeton in 1837, he entered the Princeton Theological Seminary, but was soon obliged by ill health to relinquish his studies for the ministry and in 1839 formed a partnership with John S. Taylor, then a leading publisher of New York. Mr. Taylor having withdrawn in 1840, he continued the business—subsequently to be known as Dodd, Mead and Company—under the style of M. W. Dodd until his retirement in 1870. The publications of the house during this period were chiefly theological and classical.

DODD, WALTER FAIRLEIGH (1880-). An American university professor and writer on political science, born in Hopkinsville, Ky. He graduated from Florida State College in 1898 and gained his Ph.D. at the University of Chicago; had charge of the section of foreign law in the library of Congress (1904-07); held a research appointment at Johns Hopkins University (1908-10); and was first an associate in political science (1910-11), and then assistant professor at the University of Illinois. He became one of the editors of the *American Political Science Review*. Besides contributions to legal and technical journals he is author of *Modern Constitutions* (2 vols., 1909); *Government of the District of Columbia* (1909); *Revision and Amendment of State Constitutions* (1910).

DODD, WILLIAM (1729-77). An English clergyman and man of letters. He was born at Bourne, in Lincolnshire, graduated at Clare Hall, Cambridge, in 1750, and was ordained in London, where he became a popular preacher. In 1763 he was appointed King's chaplain and tutor to Philip Stanhope, the fifth Earl of Chesterfield. For attempting to gain preferment by bribery in 1774 he was removed from the list of king's chaplains, and he lived abroad for two years. His extravagances led him in after life to forge the signature of his former pupil, the Earl of Chesterfield, for £4200; he was tried, convicted, and executed, in spite of the efforts of his friend, Dr. Johnson. Among his numerous writings are: *Beauties of Shakespeare* (1752), which supplied Goethe with his first knowledge of the poet; *Reflections on Death* (1763); a *Commentary on the Bible* (1765-70); and a *Discourse on Thoughts in Prison* (1777). Consult Fitzgerald, *A Famous Forgery* (London, 1865).

DODDER (*AS. dodder*, probably connected,

as being a yellow plant, with *AS. dydrin*, OSax. *dodro*, OHG. *totoro*, yolk of an egg), *Cuscuta*. A genus of plants referred by some botanists to the family Convolvulaceæ, and regarded by others as the type of a small distinct family, Cuscutaceæ. The plants are leafless, climbing parasites, with flowers in dense clusters; have scales on the tube of the corolla alternate with its segments, and a spiral threadlike embryo, lying in a mass of fleshy albumen. There are about 100 known species of *Cuscuta*, chiefly found in the warmer temperate parts of the globe, about 20 occurring in the United States. The name "dodder" is often extended to all of them. One or two species of *Cuscuta* are natives of Great Britain, parasitic on leguminous plants, heath, thyme, hops, nettles, etc. A species of dodder, *Cuscuta epilinum*, is very injurious to crops of flax in Germany, and leguminous crops often suffer from *Cuscuta epithymum* in the south of Europe and elsewhere. Some of these species have been introduced in clover and alfalfa seed from Europe and are fast becoming serious pests of clover and alfalfa fields. Only clean seed should be sown, and where dodder has become established the crop should be cut and burned before the dodder seeds mature. It usually appears first in isolated patches, the spreading of which may be prevented by careful attention. The seeds are slightly smaller than clover seed and may be screened out if care be given the operation. The seed of dodder germinates in the ground, but the stem soon seeks to attach itself to plants by little rootlets (haustoria) which it sends out, and the original root dies. The appearance of dodder has been described as resembling "fine, closely tangled, wet catgut." For illustration, see Plate of PARASITIC PLANTS.

DODD'RIDGE, PHILIP (1702-51). An English Nonconformist clergyman and writer. He was born in London and was educated for the ministry at Kibworth, in Leicestershire, where he became pastor of a Baptist congregation. In 1729 he received a call to the ministry and became president of the theological academy there (now New College, Hampstead). He formed a society for the distribution of Bibles among the poor and submitted to his denomination what was probably the first project for foreign missions among the Nonconformists. His principal works are: *The Rise and Progress of Religion in the World* (1745), which has been translated into many languages; *The Family Expositor* (1730-56); and his *Course of Lectures*, delivered to the students under his charge and published by the Rev. Samuel Clarke (1763). Many of his hymns are still sung, including "O God of Bethel, by whose hand," "Awake, my soul, stretch every nerve," "O happy day, that fixed my choice," "Hark, the glad sound, the Saviour comes," and "How gentle God's commands." He improved Jeremiah Rich's system of shorthand. Consult *The Correspondence and Diary of Philip Doddridge*, ed. by his great-grandson, John Doddridge Humphreys (London, 1820-31), and the biography (1880) by Stanford.

DODDS, ALEXANDER (1874-). An American editor, born in Allegheny, Pa. After graduating from Duffs College (Pittsburgh, Pa.) in 1890, he engaged in news writing and editorial work. He was associate publisher of *The Builder*, Pittsburgh (1894-96), night editor of the *Pittsburgh Dispatch* (1902), associate publisher of the *Telegraph*, Sharon, Pa. (1902-04), and night editor of the *Gazette Times*, Pitts-

burgh (1905-08). In 1908 he became managing editor of the *Christian Science Monitor*, Boston, and in 1909 vice president of the United Press Associations.

DODECANESIA (Greek for twelve islands). The name applied since the Turkish wars of 1912-13 to the group of islands occupied by Italian forces off the southwest coast of Asia Minor. The group constitutes the southern Sporades and consists, from north to south, of the islands (q.v.) of Patmos, Lipsos, Leros, Calymnos, Cos, Nisyros, Astropalia, Tilos, Symi, Rhodes, Carpathos, and Casos, besides a number of minor uninhabited islets. Sponge fishing is the principal occupation of the islanders, who are known as expert divers. Fruits and vegetables are also raised for export mainly to Egypt, but a certain quantity finds its way to the Anatolian coast. By far the large majority of the islanders are Greeks.

The islands are claimed by Greece. By the terms of the Treaty of Lausanne, which terminated the Turco-Italian war, Italy agreed to restore the islands to Turkey. The breaking out of the Balkan War, however, prevented this stipulation from being carried out. At the time of writing (April, 1914) all interested parties have agreed to let the European Powers decide jointly the fate of the islands.

DODECASTYLE (Gk. δώδεκα, *twelve* + στύλος, column). In classic architecture a term denoting a composition showing 12 columns in front or end elevation, as in the portico of the Chambre des Députés at Paris.

DODECATHEON. See COWSLIP.

DODE DE LA BRUNERIE, dōd de là brun'èr, GUILLAUME, VICOMTE (1775-1851). A French soldier, born at Saint-Geoire (Isère). He served in the engineer corps in the Rhenish, Egyptian, and Italian campaigns, distinguished himself at Rastadt, and in 1805 he became a colonel. He directed the siege operations at Saragossa in 1809, was promoted to be general of division in 1812, and maintained a magnificent defense of the fortress at Glogau in 1813. In 1823 he was commander of engineers in the Spanish campaign. In 1840 was appointed president of the commission on fortifications, and in 1840-45 completed the defenses of Paris. He received the marshal's baton in 1847—the first engineer since Vauban, it is said, to be thus honored.

DÖDERLEIN, dē'dēr-lin, LUDWIG (1791-1863). An eminent German classical scholar, born at Jena. He studied under Tiersch in Munich (1810-11), then two years in Heidelberg, and later in Erlangen and Berlin. In 1815 he became professor of classical philology in Bern, and in 1819 was called to Erlangen as rector of the gymnasium and professor of classical philology in the university. Here he remained until his death. Döderlein combined with accurate scholarship a rare enthusiasm and skill in teaching which had a most important influence on the schools and the teachers of Bavaria. His most important published works are: editions of Sophocles' *Edipus Coloneus* (1825); *Tacitus* (1841-47); *Horace's Epistles* (1856-58); *Horace's Satires* (1860); *Iliad* (1863-64). He also wrote the following treatises: *Lateinische Synonymen und Etymologien* (6 vols., 1826-38); *Lateinische Wortbildung* (1838); *Handbuch der lateinischen Synonymik* (1839; 2d ed., 1849); *Handbuch der lateinischen Etymologie* (1841); *Homerisches Glossarium* (1850-58); *Reden und Aufsätze* (1860). Consult Bursian,

Geschichte der klassischen Philologie in Deutschland, vol. ii (Munich, 1883), and *Allgemeine deutsche Biographie*, vol. v (Leipzig, 1877).

DODGE, CHARLES RICHARDS (1847-). An American expert on fibres and fibre industries. He was born in Mississippi and was educated at Sheffield Scientific School, Yale. He became associated with the United States Department of Agriculture in 1867, was for 10 years director of the Agricultural Museum, and in 1890 was appointed special agent in charge of fibre investigations for the Department of Agriculture. His *Dictionary of the Fibres and Fibre Plants of the World* (1897) is a work of considerable value, and he is also author of a number of pamphlets on fibres. He was a member of the jury of awards at a number of expositions.

DODGE, CLEVELAND HOADLEY (1860-). An American merchant, son of William E. Dodge and brother of Grace H. Dodge, born in New York City. He graduated from Princeton University in 1879. He was chosen a director of a number of banks, insurance companies, and other corporations, became treasurer of the El Paso and Southwestern Railroad and vice president of Phelps, Dodge & Co., and served as vice president of the New York Chamber of Commerce. With Y. M. C. A. interests he actively identified himself, as president of the board of trustees of the New York association and as a member of the international committee; and he was elected president of the board of trustees of Robert College, Constantinople.

DODGE, FRANCIS SAFFORD (1842-1908). An American soldier, born in Danvers, Mass. He fought in the Civil War, reentered service as first lieutenant in the Ninth Cavalry (colored) in 1866, and in 1880 was transferred to the paymaster's department with the rank of major. Thereafter he was advanced through the grades to be paymaster general with the rank of brigadier general in 1904; he was retired in 1906. In 1870, with four troops of the Ninth Cavalry, he destroyed a large Indian camp in the Guadalupe Mountains; but his most famous exploit, of 1879, consisted of a voluntary 100-mile forced march with troop D of his regiment to the relief of Major Thomas T. Thornburg, whose small force near Mill Creek, western Colorado, the Indians threatened to annihilate. Fighting their way through the Indians, Dodge and his men joined Thornburg in his rifle pits and helped to hold the enemy at bay until reinforcements arrived. For this feat, one of the most brilliant in Indian warfare, Dodge was awarded the congressional medal of honor and brevetted major in 1880.

DODGE, GRACE HOADLEY. An American leader in Y. W. C. A. and other religious, social, and educational work. She was born in New York City, a daughter of William E. Dodge and sister of Cleveland H. Dodge. Actively interested during more than 30 years in plans for social betterment (especially in increasing opportunities for self-supporting girls and young women), and having at her command part of her father's large fortune, she was called to many positions of service. At various times she was a member of the New York City school board, treasurer of Teachers College (Columbia University), and president of the Working Girls' Society. She built a chain of hotels for working girls and through personal influence and quiet but notable generosity accomplished the unification and

assured success of the Young Women's Christian Associations of the United States—this was her great work. She was elected president of the national board of the Y. W. C. A. and became a member of the world's committee. In 1912-13 she gave \$350,000 for the national board and metropolitan association buildings in New York City. Miss Dodge edited *Thoughts of Busy Girls* (1892), wrote *A Bundle of Letters to Busy Girls on Practical Matters* (1897; trans. into several foreign languages), and is co-author of *What Women Can Earn* (1899).

DODGE, GREENVILLE MELLE (1831-). An American soldier and civil engineer. He was born at Danvers, Mass., and was educated at Norwich University, Vt. He was a member of the government survey along the Platte, one of the first surveys for a railway to the Pacific. He fought throughout the Civil War and rose to the rank of major general of United States volunteers. In 1864 he commanded the Sixteenth Corps of General Sherman's army in the campaign before Atlanta (May to September) and subsequently succeeded Rosecrans as commander of the Department of Missouri. In 1866-70 he was chief engineer of the Union Pacific and in 1871-81 of the Texas and Pacific Railway. From 1867 to 1869 he served as a member of Congress (Republican) from Iowa, and in 1898 was made president of the commission appointed to investigate the charges of mismanagement relative to the Spanish-American War.

DODGE, JACOB RICHARDS (1823-1902). An American agricultural statistician, born at New Boston, N. H. He received an academic and technical education. After teaching in Mississippi (1845-49) and editing a paper at Nashua, N. H. (1850-54), he was editor of the *American Ruralist* at Cincinnati, Ohio, in 1857-61. For 24 years he was chief of the reports of the United States Department of Agriculture, and he also contributed to the agricultural press and to the tenth census and wrote pamphlets on rural economics. He had charge of foreign commissions for the Department of Agriculture in 1873 and in 1887, and in 1893 joined the editorial staff of the *Country Gentleman*. His publications include: *Red Men of the Ohio Valley* (1860); *West Virginia: Its Farms and Forests, Mines and Oil-Wells* (1865); *Farm and Factory* (1884).

DODGE, JAMES MAPES (1852-). An American mechanical engineer, born at Waverly, N. J. He was educated at Cornell University and at Rutgers College. His important work was in connection with the improvement of conveying machinery and appliances. Settling in Philadelphia, he became chairman of the Link Belt Company and president of the Dodge Coal Storage Company and of the J. M. Dodge Company. He was at one time vice president of Franklin Institute, and in 1903 he was president of the American Society of Mechanical Engineers. His address on *The Money Value of Technical Education Training* was published in 1903.

DODGE, MARY ABIGAIL (c.1830-96). An American writer, known as "Gail Hamilton," born at Hamilton, Mass. She was an editor of *Our Young Folks*, Boston (1865-67). Her writings were aggressive, brilliant, and popular, though in the main ephemeral. She wrote: *Gala Days* (1863); *Red Letter Days in Applethorpe* (1866); *Woman's Wrongs* (1868); *The*

Battle of the Books (1870); *Woman's Worth and Worthlessness* (1872); *Sermons to the Clergy* (1875); *Our Common School System* (1880); *The Irrepressible Book* (1885); *James G. Blaine* (1895); *Chips, Fragments and Vestiges* (1902), Ed. by H. A. Dodge. Her pen name was Gail Hamilton, the former word being the last syllable of Abigail, the latter her birthplace. Consult H. A. Dodge, *Gail Hamilton's Life in Letters* (2 vols., 1901).

DODGE, MARY ELIZABETH MAPES (1838-1905). An American editor, poet, and juvenile writer, a daughter of Prof. James J. Mapes. She was born and educated in New York and became the wife of William Dodge, a lawyer of that city, but was soon left a widow. She began literary work on the staff of *Hearth and Home* and in 1873 became editor of *St. Nicholas*, the juvenile magazine, which under her direction came to occupy a field practically undisputed in the United States. A frequent contributor to other periodicals, she also wrote several volumes of juvenile verse and prose, of which the more noteworthy are *Hans Brinker; or, The Silver Skates* (1865; a new illustrated ed., 1913; translated into five European languages and crowned by the French Academy); *Theophilus and Others* (1876); *Donald and Dorothy* (1883); *The Land of Pluck* (1894); *The Golden Gate* (1903). She also published collections of poems: *Along the Way* (1886); *When Life is Young* (1894); *Poems and Verses* (1904).

DODGE, RICHARD ELWOOD (1868-). An American geologist, born at Wenham, Mass. He was educated at Harvard University in 1890 and taught geology there for four years; taught at Teachers College (Columbia University), where he became professor of geology in 1897; and was also an assistant geologist of the United States Geological Survey (1890-95). In 1899 he became associate editor of the *Bulletin of the American Geographical Society*, and he was editor of the *Journal of School Geography* (1897-1901), the *Journal of Geography* (1902-10), and of the *Annals of the Association of American Geographers*. Besides many articles on the teaching of geography and on the southwestern part of the United States as the home of ancient peoples, he is also author of *Reader in Physical Geography for Beginners* (1900); *Geography in the Horace Mann Schools* (1901); *The Teaching of Geography in Elementary Schools* (1913), with C. A. Kirchwey; and a series of textbooks on geography.

DODGE, THEODORE AYRAULT (1842-1909). An American soldier and military historian. He was born in Pittsfield, Mass., and was educated abroad, studying military science in Berlin under General Von Frohreich of the Prussian army and graduating at the University of London in 1861. He then returned to the United States, enlisted as a private in the Federal army, lost a leg at Gettysburg, and rose to the rank of major in the Veteran Reserve Corps in 1864. He was brevetted colonel of Volunteers in December, 1865, was appointed captain in the regular service in July, 1866, was brevetted lieutenant colonel in the regular army in 1867, and served as chief of the bureau of enrollment in the War Department until 1870, when he was retired. He is best known as a military historian and critic, and his *Bird's Eye View of our Civil War* (1883; later ed., 1897) is perhaps the best brief popular account

of the war . . . of 1861-65. His *Campaign of . . .* (1881) has also been highly commended. Besides many articles for the magazines, he has also published: *Patroclus and Penelope: A Chat in the Saddle* (1883); *Great Captains* (1886); *Riders of Many Lands* (1893); *Alexander* (1890); *Hannibal* (1893); *Cæsar* (1892); *Gustavus Adolphus* (2 vols., 1890-95); *Napoleon* (1904), the last five works forming part of a projected history of the art of war, to be completed in six volumes.

DODGE, WILLIAM EARL (1805-83). An American merchant and philanthropist. He was born in Hartford, Conn., was educated in the public schools, and worked for a short time in his father's cotton mill near Norwich. Removing to New York with his father, he entered a wholesale dry-goods store, and finally, after eight years, went into business by himself. In 1833 he became a member of the firm of Phelps, Dodge & Co. He became interested in railroad and insurance corporations and invested largely in mines and woodlands. He was interested in temperance and religious work and was one of the most generous supporters of the Young Men's Christian Association and the Freedmen's Bureau. He was a member of the Peace Convention of 1861 and was a Republican member of Congress in 1866. President Grant appointed him a member of the Indian Commission. At his death he left bequests to religious and charitable institutions. Consult Martin, *William E. Dodge, the Christian Merchant* (New York, 1890).

DODGE CITY. A city and the county seat of Ford Co., Kans., 126 miles west of Hutchinson, on the Arkansas River, and on the Atchison, Topeka, and Santa Fe and the Chicago, Rock Island, and Pacific railroads (Map: Kansas, C 7). The city contains St. Mary's of the Plains Academy (Roman Catholic), United States Land Office and Weather Bureau buildings, and a Carnegie library. Dodge City has division offices and machine shops of the Santa Fe railroad and is the centre of a stock-raising and wheat-growing district. In the seventies it was famous in the West as a lawless Texas cattle-shipping point. It owns its water works and has adopted the commission form of government. Pop., 1900, 1942; 1910, 3214. Consult R. W. . . . *Dodge City, the Cowboy Capital*.

DODGEVILLE. A city and the county seat of Iowa Co., Wis., 47 miles west by south of Madison, on the Chicago and Northwestern and the Illinois Central railroads (Map: Wisconsin, C 6). Deposits of lead and zinc occur in the vicinity, and the city has considerable trade in live stock and . . . products. The manufacture of . . . is the chief industry. Dodgeville was the early home of Territorial Governor Dodge, for whom it is named. Pop., 1900, 1865; 1910, 1791.

DODGSON, dōj'son, CHARLES LUTWIDGE (1832-98). An English author, best known by his pseudonym, LEWIS CARROLL. He was born in the village of Daresbury, near Warrington (Chester), England. Educated at Oxford, he took deacon's orders in 1861, and from 1855 to 1881 he was mathematical lecturer at Christ Church. He was an acute mathematician, with a penchant for the intricate and ingenious, and made to mathematical literature a contribution of high rank in his *Euclid and his Modern Rivals* (1879), eccentrically cast in dramatic mold and interspersed with jokes. His mathematical pub-

lications include a *Syllabus of Plane Algebraical Geometry* (1860) and *An Elementary Treatise on Determinants* (1867). But he is best known as the originator of an unique literary genre in his *Alice's Adventures in Wonderland* (1865), with its continuation in *Through the Looking-Glass and What Alice Found There* (1871), both admirably illustrated by Sir John Tenniel. These books display a delightful combination of mad absurdity and subtle fancy. Their grotesque situations compose a peculiar literary tradition. *The Hunting of the Snark* (1876), an episode none the less enjoyable because its meaning remains unsolved, was nearly as successful. *Sylvie and Bruno* (1889) and *Sylvie and Bruno Concluded* (1893) were inferior to the previous works. A dramatization of the Alice volumes by Saville Clarke was presented in London in 1886. For a full account of Dodgson's interesting personality, consult the *Life and Letters*, ed. by Collingwood (London, 1898), and for a brief account, B. Moses, *Lewis Carroll* (New York, 1910).

DODDINGTON, GEORGE BUBB, BARON MELCOMBE (1691-1762). An English politician. He was the son of Jeremiah Bubb, but took the name of Doddington in 1720, on inheriting a large estate from an uncle of that name. He studied at Oxford, was elected member of Parliament for Winchelsea in 1715, and from 1715 to 1717 was envoy extraordinary to Spain. He became very wealthy, controlled five or six votes in Parliament, and had an inordinate desire to become a power in politics and to be elevated to the peerage, and bartered away his votes first to one party and then to another. He was first a follower of Walpole, deserted to the Prince of Wales, and was later allied in turn to Argyll, Henry Pelham, Newcastle, and Bute. His variability and the venality of his half-dozen votes made him the frequent butt of political satire and caricature. He was a lord of the treasury from 1724 to 1740, became treasurer of the navy under Henry Pelham in 1744, and in 1755 held the same position under the Newcastle-Fox coalition. For his support of Lord Bute in 1761 he was rewarded by being created Baron Melcombe of Melcombe Regis, Dorsetshire. Doddington was one of the last of the "patrons" and gathered about him some of the best-known literary men of the time, including Young, Thomson, and Fielding. His *Diary*, published in 1784, is an interesting picture of the political and social life of the times.

DODO (Neo-Lat. *didus*, Port. *doudo*, simpleton, possibly connected with Devonshire, Eng. *dold*, *dolt*, lit. dulled, from *dull*), or **DRONTE** (Dutch, of unknown origin, bloated). An extinct specialized pigeon, of which we have knowledge of two species, the Mauritius dodo (*Didus cucullatus*), confined to the island of that name, and the Réunion dodo (*Didus solitarius*) of the island of Bourbon or Réunion. These birds, with the solitaire (*Pezophaps*), represent the family Dididae. They became extinct towards the end of the seventeenth century. It is described by several voyagers of the sixteenth and seventeenth centuries, who also spoke of it as "walghvogel" and "dronte," and seems even to have been brought alive to Europe. The descriptions of those who saw it are confirmed by several more or less rude drawings preserved in various European libraries and museums, especially in Holland. These represent a bird larger than a swan; of a very heavy and clumsy

not written before the beginning of the second century B.C.

DOFFER (from *doff*, ME. *doffe*, from *do* + *off*). That part of a carding machine which takes the sliver wool or cotton from the cylinder when carded. The invention of the doffer was claimed by both Arkwright and Hargreaves. See **CARDING**.

DOG (AS. *doega*). A carnivorous mammal of the family Canidae, especially the genus *Canis*, and more specifically one that is domesticated. The dog, or dogs, considered as a subject for present purposes, requires treatment from several points of view, viz.:

1. As a tribe, in its zoölogical relations.
2. As a more limited group, according to the ordinary acceptation of the term "dog."
3. As to the relation of domestic dogs to mankind.

The dog tribe includes the whole of the carnivorous family Canidae, for the zoölogical history and character of which see **CANIDÆ**. It embraces a variety of forms which are divisible into at least five groups:

- (a) The long-eared fox dog (*Otocyon*) of South Africa, which is the most generalized member of the family. See **FOX DOG**; **OTOCYON**.
- (b) The bush dog (*Icticyon*) of South America, a specialized aberrant form. See **BUSH DOG**.
- (c) The foxes, forming what Huxley called the alopecoid or vulpine series, and embracing the typical foxes, fennecs, corsacs, kit foxes, etc. See **FOX**; **FENNEC**; **ETC.**
- (d) The hunting dog (*Lycaon*) of South Africa. See **HUNTING DOG**.
- (e) The wolves, forming Huxley's thooid or lupine series, in which are found the wolves, jackals, fox dogs, crab-eating dog, and similar wild and domestic dogs of the world.

The first four of these subjects are treated of elsewhere, as indicated by the cross references noted above. In the last group (e), wolves, jackals, fox dogs, etc., many of the individual forms are separately described under their names. There remain then for consideration here: (1) a group which may properly be designated wild dogs, and (2) the domestic dogs.

Wild Dogs. There exist in southeastern Asia and in Australia three or four species of canine animals which are hardly separable from the genus *Canis* by distinct characters of importance, yet which seem to form a natural group that may be consistently separated as a genus or subgenus *Can.* characterized mainly by the lack of the small last tubercular molar tooth on each side of the lower jaw (as was the case with fossil *Cynodictis*), by having a comparatively short muzzle, slightly convex facial outline, rather short legs, with long hair between the footpads, and 12 to 14 mammae instead of the normal 10. The dingo may, for the present, be included in this group. Their resemblance in general is to jackals, of which Huxley considers them a locally modified type, but they have a more "doggy" appearance than either jackals or wolves. It is from this resemblance that the designation "wild dogs" arises, and not from the belief that any of them is a direct progenitor of modern domestic dogs, even though individuals of all of them may occasionally have been tamed and attached to human owners. There is much general resemblance among them. In size they somewhat exceed the jackals, being from 30 to 38 inches long exclusive of the tail, which in all is long (about

two-fifths of the length of the body) and bushy, like that of a jackal or a fox. All have comparatively long and coarse hair, the prevailing color of which is rust red in summer and lighter in winter, and generally decidedly darker on the back and tail than on the chest, belly, and inside of the legs. They go abroad in the daytime rather more than at night, hunt in packs of a dozen or more, led by an old male, and dwell by families, sometimes in crevices of rocks, hollow trees, and similar retreats, but they do not dig burrows.

The best known of these is the Indian wild dog (*Canis*, or *Cyon*, *deccanensis*), which inhabits the forested parts of the whole Himalayan region, the treeless area of eastern Tibet, and southward as far as the great forests of India. The more southerly form, known as the *dhole* in the far south of the peninsula, *sona kuta* (golden dog) in central India, and *kolsun* among the Mahrattas, has been set apart by some students (see *Mivart, Proceedings of the Zoölogical Society of London*, 1890, p. 88) as a separate species (*Canis primævus*), but the distinction is much doubted. The native name of the northern form is "buansu," to which the reader is referred for further particulars.

The Malay wild dog (*Canis rutilans*) is a rather smaller species, which occurs east of Bengal throughout the Malay Peninsula and also in Java, Sumatra, and perhaps Borneo. Whether the wild dog of Upper Burma belongs to this or the preceding species is dubious, and this doubt lends color to the opinion of some naturalists that these Eastern forms are not specifically separate from the Indian one. Blanford regards the Malay dog as distinct and describes it as smaller, more slender in body and limbs, with shorter and harsher hair, a deep ferruginous red. Its habits in general seem to be those of the Indian dog.

The Siberian wild dog (*Canis alpinus*) much resembles the others in features and habits. It inhabits the forested regions of northern Asia as far south as the Altai Mountains and subsists almost entirely on deer, which it hunts in companies, pursuing them so constantly that it is said occasionally to destroy or drive away all the deer in certain districts. It also hunts the ibex in the high mountains. It appears that this semi-Arctic dog changes its summer coat of fox red for a long and woolly winter dress of yellowish white, as do the Arctic foxes.

There remains to be mentioned the dingo (*Canis dingo*), which by some naturalists has been set apart in a genus (*Dingo*) by itself. It inhabits Australia only and bears a considerable resemblance to the Himalayan wild dog. Although numerous in wild packs, it is also kept domesticated by the native Australians, by whose remote ancestors it may have been introduced into that island from the north. See **TINGO**.

Interbreeding, Tamability, and Voice. A few special considerations may well be made at this point, as tending to illuminate the relation which domestic dogs bear to the wild forms. First, it appears certain, although it may almost never occur under natural conditions, where the primal instincts of kinship prevent crossing of "species," that all the various canine animals may interbreed and produce offspring. This has been accomplished in the case of some species in captivity or a state of semidomestication. Whether these hybrid offspring are fertile with each other in every case, or usually, is not

so certain. A few instances are recorded in which they have been found to be so.

In respect to tamability canine animals are much superior as a tribe to feline animals, and perhaps no species intelligently tried has proved intractable. Pet examples of almost every species have been found among the savage or partly civilized peoples of the world, and the owners of menageries find even wolves submitting well to the trainers. There seems to be in the canine nature, disposing them to gather in packs and hunt in concert, and strengthened by these practices, a sympathetic element wanting in most other carnivores, the cultivation of which by man has led to the close affiliation between him and his dog, and to the expansion of the dog nature into the beautiful fidelity, appreciation, and affection it exhibits in its higher examples.

Wild canines may be said to howl, to yelp, to whine, to growl, and even—as some have mentioned—to bay when pursuing quarry; but none truly barks. Much attention was paid to this point by Mr. Bartlett, for many years keeper of the Zoölogical Gardens of London, who concluded from his observation of the captives of many wild species under his care that the barking of domestic dogs is an acquired habit, but one into which wild canines quickly fall by imitation. "A well-known instance of this," Mr. Bartlett wrote (*Proceedings of the Zoölogical Society of London*, 1890), "occurred under my notice. A wild Antarctic wolf, after a few months, hearing the barking of dogs in the immediate neighborhood, began to bark, and succeeded admirably. The same thing has happened to my knowledge in the case of pure-bred Eskimo dogs and dingos." See PLATES OF WOLVES AND WILD DOGS; FOXES AND JACKALS.

Fossil Dogs. The ancestors of the dogs, wolves, foxes, and jackals may be traced back through the Pliocene into the Miocene and Eocene periods, beyond which the ancestral forms become so generalized in type that they can with difficulty be placed in their respective categories, or separated from the ancestors of the civets and bears. Indeed, these families, together with the Canidæ, had a common origin in the Eocene carnivores, such as *Amphicyon*, *Calecyon*, *Cynodictis*, which are synthetic types. The modern family of Canidæ is a diphyletic group; i.e., it has had two sources. One series, terminating in the jackal, is thought to have had a common origin with the Viverridæ in *Cynodictis*. The second series, comprising the true dogs, foxes, and wolves, traces its ancestry from *Daphænus* and the earlier *Amphicyon*, which latter also gave rise to the bears.

Origin of Domestic Dogs. A great amount of discussion has taken place over the question of the origin of domestic dogs—whether they represent a separate species, or are the descendants of some existing canine species, or are of composite stock. The present diversity is so great that some dogs are no larger than the heads of others; that some are almost totally hairless, while others wear coats of hair longer than is elsewhere known among mammals, and some have narrow skulls with prolonged jaws, while in others the width of the skull is greater than its anteroposterior length, and the jaws hardly protrude beyond the forehead. Equally remarkable differences separate them temperamentally. The question then arose: Could all these variations be accounted for as the result of domesti-

cation and selective breeding acting upon a single species; and, if so, what traces remained to indicate what that species is, or was? It would be unprofitable to enter into all the speculations that have been recorded. Some have held that our dogs are only modified descendants of a wolf, the same or essentially similar to the modern common wolf; others, that all dogs are modified jackals. It has been extremely difficult for either school to find characteristics held in common by all varieties of dogs by which to make their comparisons and support their arguments. The upcurling of the tail, the drooping of the ears, the presence of "buttons" of tan over the eyes, and other alleged characteristics are not universal and seem comparatively unimportant. Probably the most singular characteristic possessed by dogs as contrasted with wild canines of every sort is a matter of voice—the bark; but those on the borderland of dogdom, such as the Arctic sledge dogs and the dingo, do not utter this peculiar sound, and, on the other hand, dingos, Eskimo dogs, and even wild canines, quickly acquire the habit when associated with tame dogs, by imitating them more or less completely. See DINGO.

The consensus of modern scientific opinion is that our dogs represent the union of several strains, which during the long ages since this animal began to associate with wandering mankind, have been intermixed until only an indefinite trace of the original wild ancestry can be found; and that this process has continued to the present time. An important element, no doubt, is wolf; an equally important element, jackal. Foxes seem to have had a less part in the mixture, but the former assertion that foxes were unable to crossbreed with dogs is now known to be erroneous; such hybrids are uncommon, but do exist, and are no less fertile than other canine crosses, such, e.g., as those between domestic dogs and wolves or jackals, which constantly happen on the frontier of civilization, both by accident and by intention on the part of the owners. But it must be remembered that wolves and jackals are of various species and exist in many parts of the world, and that there are various other members of the dog family, such as the "wild dogs" of the Orient, described earlier in this article, the foxes, and the fox dogs and wolves of South America. Moreover, sufficient time has elapsed in all probability since the domestic races began for species of a smaller sort to have become extinct, perhaps largely through man's agency, partly by killing them, and partly by absorbing them into his domestic family. The peculiarities of certain races, such as the Japanese pugs and the hairless dogs of tropical America, are so great as to be accounted for with difficulty, except upon the supposition that they are the descendants of extinct species.

All canine animals exhibit, more or less plainly, the qualities which have contributed to make the character and value of the domestic dog what they are. They are courageous, quick-witted, and accustomed to possessing and defending home and property (their captures), and to the exercise of both nose and eyes, whose faculties are highly developed. More important, however, as rendering them susceptible to taming and the offer of human friendship, is their practice of hunting in companies and aiding one another, which has developed in them a social disposition much in excess of that in any other

class of carnivores, and given them a sense of mutual dependence easily transferred to human companions and increased by continual human association. Hence the fact that in every part of the world, and from time immemorial, men have been found to own dogs, and the history of the dispersion of his dogs is bound up with the problem of the dispersion of man himself. The practice appears as far back as humanity can be traced. We may not be sure that Paleolithic man kept dogs as camp mates, but "Neolithic" man, he of the stone village on the hill and of the pile-built dwelling on the lake, certainly possessed and used them as an aid in keeping his flocks and herds. The oldest monumental remains of the valleys of the Indus, the Euphrates, and the Nile, show that dogs were common among these early peoples and in great diversity. Certain types well known to-day may be recognized, and will be referred to more particularly in the special articles on those breeds. Consult Berjeau, *The Varieties of Dogs* (London, 1865), a treatise upon dogs as they are found depicted in old sculptures, pictures, engravings, and books to the end of the seventeenth century.

It is certain that the first ones tamed were of local species, some of which in all probability have since become extinct. As tribes enlarged and spread out, their dogs would go with them. Here and there they would encounter and coalesce with other peoples, and an intermingling of dogs would follow. This, going on indefinitely and complicated by constant intermixture with new blood from the forest—for in no group of animals is interfertility more general—would speedily bring about a great variety of forms. In addition to this, however, there must have gone on from the very first, besides the varying influences of new climate, food, and general environment, a certain amount of selective breeding.

It has been held by Professor Shaler and others that the first motive leading to domestication of the dog was to provide a resource against the recurring famines that afflict aboriginal life, while others suppose the animal's aid in hunting first made it valuable. Undoubtedly, then as now, the dog was eaten on occasion, but it would certainly make itself so useful as a watchdog and a hunter as quickly to win regard; and there is no doubt that the personality of the animal would appeal to the affection of the primeval savages as it does to-day. No other human beings are regarded as so rude and autochthonous as the northern Australians, yet while they eat both the wild and tame dingoes, and use the latter in hunting, they regard many of them as pets, lavish affection upon them, and even nurse the puppies at the women's breasts. In recognition of these qualities, the best or most interesting puppies and older dogs would naturally be saved when any were to be killed for food or other purpose. In such isolated circumstances as those of the Australians, where there is free and constant intercourse between the wild stock and the tame, this would have little effect; but in general, where the mixture of several wild breeds had already produced diverse hybrids, the unconscious selection thus brought about would soon be effective, and would be followed, as civilization began, with a more intelligent and definite kind of choice, which must have originated selective breeding long before any his-

tory of it begins. It must have been intelligently and persistently practiced, in fact, long before the earliest civilized records, for monuments inscribed four or five thousand years ago bear pictures of widely diversified and perfectly bred races of dogs, such as greyhounds. Consult Lydekker, *Mostly Mammals* (London, 1903), and Duerst, *Martin Wilckens Grundzüge der Naturgeschichte der Haustiere* (Leipzig, 1905).

Varieties of Domestic Dogs. No one probably has ever attempted to make a complete

GROWTH OF A DOG'S TEETH.

Development of dentition in the lower jaw at various successive ages: 1, two days; 2, four months; 3, six months; 4, nine months; 5, eleven months; 6, four years.

catalogue of the varieties of domestic dogs known throughout the world, but Fitzinger estimated the number in 1876 at about 185. All these fall into certain groups, or types, as will presently be noted; and the study of their points of likeness and unlikeness has been made by several recent investigators of the law of variation. One of the most recent and successful of these was a comparison by Windle of the skulls of some 60 varieties, representing most of the types, the results of which were extensively tabulated and discussed in the *Proceedings of the Zoological Society of London* for 1890. He says that the most noteworthy fact learned from his comparative measurements of dog crania was that the averages of the different breeds, especially in points relating to some of the teeth, differ very little from one another; in other words, that, speaking generally, the teeth in one dog are relatively to the skull very similar in size to those of any other. It is also to be noticed that the range of variation in any breed is much greater, in almost every case, than that existing between any two breeds. Mr. Windle says:

"The extreme variations in any breed are probably due to the fact that, strictly speaking, so few animals of the same group are really in any sense of the same breed. The various members of a carefully selected strain of terriers, for example, bred by one breeder, might be comparable with one another, and yet quite different in descent from another and perhaps equally good strain belonging to another breeder and to another part of the country. With dogs bred for show purposes, as so many of the pure strains are, and with constantly varying requirements of fashion, all sorts of crosses, as any manual of dog breeding will show, have been tried with a view of attaining the ideal, whether of symmetry, pace, or carriage. That such

 7. GRIFFON, "Blitz von Kaiserlauten."
 8. COLLIE, "Emerald Eclipse."

crosses should, at times at least, leave their marks upon the skulls, and cause differences in breeds which cannot be accounted for, is, of course, to be expected. The presence of the disturbing factor can be appreciated, though its exact nature cannot always or even frequently be ascertained with any correctness. Thus, amongst the 11 bulldogs' skulls which we have examined, there was one which differed in measurements considerably from the rest. It was nearly one centimeter longer than any other, and, what is much more significant, it was seven centimeters longer than it was broad, the average for the others being about three or four centimeters. Moreover, its palate was 1.90 centimeters longer than it was broad, whilst in every other case but one the breadth exceeded the length. In the second case the length was .90 greater than the breadth of the palate, and the length of the skull nearly five centimeters greater than the zygomatic width. We cannot doubt that both of the skulls above mentioned were those of dogs in whom, to a greater or lesser degree, there was an admixture of strain, of what kind it is impossible to say. And what is true of these is doubtless true also in lesser degree of the greater number of specimens coming under examination. It thus becomes apparently a hopeless task to look for evidence as to the proximate or ultimate derivation of the breeds of domestic dogs in their skulls or teeth."

Having arranged his skulls with reference to relative length and breadth, Mr. Windle found that the distinctly broad-headed dogs form a well-marked group by themselves, including the Chinese pug-nosed spaniel, the pug, bulldog, black-and-tan toy terrier, and King Charles spaniel, a considerable interval existing between these and the next. All these are highly artificial breeds, which require great care and attention in order to prevent deterioration, with its consequent elongation of the skull. Next to this group comes one, largely consisting of terriers, with heads inclining to be broad. A miscellaneous group next follows, gradually decreasing to the distinctly narrow-headed dogs, such as the Irish wolf dog and the greyhound.

These investigations demonstrated the fact that in the highly artificial broad-headed dogs elongation of skull and palate is a sign of impure breeding, an evidence of admixture with the broad-headed strain of that of some other and narrower-headed dog. Examples of this may be seen almost any day in the streets in the shape of the half-bred pugs, in which the elongated muzzles present so great a contrast with the short, square faces of their pure-bred cousins. We have no facts before us to prove whether the long-headed dogs, such as greyhounds, tend to become broader when impurely bred, but it is highly probable that they would do so, and consequently that the dogs at both ends of the scale would, under the influence of promiscuous interbreeding, tend to approximate to the average head.

Classification. Breeds of dogs have been variously classified. One Roman grouping mentioned by old writers was into fighters (*pugnaces*); wise dogs (*sagaces*), and swift-footed ones (*celeres*); the *sagaces* were said to have come from Greece, and the *pugnaces* from Asia. Another ancient grouping was into house dogs, sheep dogs, and sporting dogs; the last embracing fighters, hounds hunting by scent and hounds

hunting by sight. Modern naturalists have substantially agreed upon six groups, with considerable differences in composition, however. Thus, Col. Hamilton Smith, about 1830, arranged the list as follows: 1. The wolf dogs, including the Siberian dog, Eskimo dog, Iceland dog, Newfoundland dog, Nootka dog, sheep dog, great wolf dog, great St. Bernard dog, Pomeranian dog, etc. 2. The watch and cattle dogs, including the German boarhound, Danish dog, matin dog of the North American Indians, etc. 3. The greyhounds, including the Brinjaree dog, different kinds of greyhound, Irish hound, lurcher, Egyptian street dog, etc. 4. The hounds, including the bloodhound, old southern hound, staghound, foxhound, harrier, beagle, pointer, setter, spaniel, springer, cocker, Blenheim dog, water dog, or poodle, etc. 5. The cur dogs, including the terrier and its allies. 6. The mastiffs, including different kinds of mastiff, the bulldog, pugdog, etc.

The latest arrangement is that by Windle, based upon the shape of the skull and other features rather than upon form and function, yet not greatly different from its predecessors. It is as follows:

I. *Wolflike Dogs*.—Arctic sledge dogs; shepherd dogs (collies); Newfoundland dog; St. Bernard, rough and smooth, and Pomeranian or Spitz dog.

II. *Greyhounds*.—Old Irish wolf dog; modern Irish wolf dog; greyhound; Italian greyhound; West Indian naked dog ("presumably").

III. *Spaniels*.—All varieties.

IV. *Hounds*.—Bloodhound; foxhound; harrier; otter hound, beagle, pointer, setter, etc. (hunting dogs).

V. *Mastiffs*.—Mastiffs; bulldogs; pugs, etc. (the "watchdogs," notable, as a class, for the extraordinary range of size).

VI. *Terriers*.—English, Scotch, Irish, and Skye terriers; fox terriers (pure), black-and-tan terriers, turnspits, and the Oriental pariah dogs.

For the purposes of this *ENCYCLOPÆDIA* the domestic dogs have been grouped, and will be found described under the following headings: CHOW CHOW; FIELD DOG; GREYHOUND; HAIRLESS DOG; HOUND; NEWFOUNDLAND DOG; POODLE; PUG; ST. BERNARD DOG; SHEEP DOG; SLEDGE DOG; SPANIEL; TERRIER.

The Dog in Law. The dog occupies an anomalous position in the law. Though not belonging to the animals of a wild nature (*feræ naturæ*), he was not, on the other hand, like most other domestic animals, regarded by the common law as the subject of property—at least, while alive; though it was held in an early case that a man might have a right of property in the skin of a dead dog. He belonged, like the cat, the fox, and the monkey, to animals of a "base nature." The utility of certain species of dogs, especially in hunting, gradually gained for them a certain legal recognition, and in the time of Elizabeth we find it laid down that the law takes notice of greyhounds, mastiffs, spaniels, and tumblers, and that an action in trover will lie against any one who takes and detains such a dog from the owner. But the offense was not punishable criminally at common law. By a statute of George III (1770), however, it was enacted that the stealing of any dog was a misdemeanor, punishable by fine, imprisonment, or whipping. In a few of the United States similar statutes

have been passed, but in general the dog retains his inferior common-law status in this country, as not the subject of larceny. In most of the States, however, it is probable that an action in trover would lie for the recovery of a valuable dog, though the question has been passed upon only in a few jurisdictions.

On the other hand, it is generally lawful to keep a dog, and in the absence of general laws or local ordinances to the contrary, to allow him to go at large. The owner is not responsible for injuries caused by his dog unless the latter is of a savage or vicious temper and the owner knew or had reason to believe that the animal was dangerous. In the latter case the owner is absolutely responsible without proof of special negligence on his part. So, if a dog, because of his vicious temper, becomes a common nuisance, the owner may be indicted. And even in a State in which a dog is recognized as property, he may be killed in self-defense, or after due notice to the owner if dangerous to the community. It is common in many jurisdictions to impose a license or other tax on dogs, and in nearly all States the terms on which they may be kept and allowed to run at large are regulated by statute or by municipal ordinances. It is not a violation of the constitutional protection of property in the United States to exterminate dogs in the public interest. See PROPERTY; TORT; and consult the authorities there referred to.

Bibliography. Stonehenge, *The Dog*, etc. (see below); Gray, "Varieties of Dogs," in *Annals and Magazine of Natural History*, 4th series, vol. iii (London, 1869); Huxley, "Cranial and Dental Characters of the Canidæ," in *Proceedings of the Zoological Society of London* (ib., 1880); Mivart, *Dogs, Jackals, Wolves, and Foxes* (ib., 1890); Wortman and Matthew, "The Ancestors of Certain Members of the Canidæ, Viverridæ, and Procyonidæ," *Bulletin of the American Museum of Natural History*, vol. xii (New York, 1899); Beddard, *Mammalia* (London, 1901). The literature relating to domestic dogs, and especially to those used in the chase, is exceedingly extensive in all languages. A selection of important books in English is as follows: Caius, *De Canibus Britannicis* (ante 1572), a Latin essay by a celebrated naturalist of the sixteenth century; George Tuberville, *The Noble Art of Venerie or Hunting* (London, 1576), the earliest illustrated book of the dog; J. H. Walsh ("Stonehenge"), *Dogs of the British Islands* (ib.); id., *The Dog in Health and Disease* (ib., 1859). Standard and modern works: W. Youatt, *Training and Management of the Dog* (London and New York, 1859); Rev. William Pearce ("Idstone"), *The Dog* (ib., 1872); Vero Shaw, *Illustrated Dog Book* (London, 1890); id., *History of the Kennel* (New York, 1913); id., *The Dog in Health and his Treatment in Disease* (ib., 1892), valuable especially as a veterinary guide; R. B. Lee, *A History and Description of the Modern Dogs* (London, 1897); H. W. Huntington, *The Show Dog* (Providence, 1901); H. Bylandt, *Dogs of All Nations* (Philadelphia, 1905); F. T. Barton, *Our Dogs and All about Them* (Boston, 1911).

DOG'BANE (*Apocynum*). A genus of plants of the family Apocynaceæ. Some of the species are shrubby, some herbaceous; some extend into colder climates than is usual for plants of this

order. The Dogbane of North America (*Apocynum*) is a perennial herbaceous plant, about 4 feet high, with smooth stem, much milky juice, smooth ovate leaves, and whitish rose-colored flowers. It grows in open barren places from Greenland to Canada. It is valued for the emetic, cathartic, and tonic properties of the bark of its root. The root of Canadian or Indian hemp (*Apocynum cannabinum*) possesses similar properties. This species abounds throughout the western portion of the United States. It furnishes a fine, long, strong, white, easily separable fibre, employed to a considerable extent by the Indians, who manufacture it into numerous articles. (See APOCYNUM.) For illustration, see Plate of DAHLIA.

DOG'BERRY. A city officer and servile clown in Shakespeare's *Much Ado About Nothing*. He utters the much-quoted phrase, "Write me down an ass."

DOG BREAKING. See FIELD DOG.

DOGCART. See CART.

DOG DAYS. See CANICULA.

DOGE, dōj (It., variant of *duca*, duke, from Lat. *dux*, leader). The name of the chief magistrate in the former republics of Venice and Genoa. The first Doge of Venice, Paolo Lucio Anafesto, was elected by the people in 697. Before that time the various islands had been governed by tribunes, but the divided authority had been found inefficient in times of danger. At first the power of the Doge was not strictly defined and depended mainly upon the character of each incumbent, though the consent of the General Assembly was necessary for a declaration of war or the making of a treaty. An able Doge usually endeavored to make his office hereditary, and in order to do this to have his son appointed as consort; but the people resisted this tendency, as they did not wish "to live under a lord," and by 1033 the antidynastic principle triumphed and the election of the Doge Consort was declared illegal. In order to aid the chief magistrate in his constantly increasing duties, instead of a consort, two *Consiglieri Ducali*, or privy councilors, were appointed. At the same time, as a restriction upon his power, the Doge was obliged to call the more prominent citizens to aid him with their advice. This was the foundation of the Senate, or *Pregadi*. From this time the power of the Doge was gradually restricted by legislative enactment. In the earlier periods the usual remedy against tyranny had been violence, and several doges had been deposed, blinded, or put to death, but after 1033 tyranny was guarded against by constitutional checks. In 1172 the Great Council, *Maggior Consiglio*, of 480 members was created. These represented the different sections and held office for one year; they made appointments to office and prepared all business which was to go before the General Assembly. In addition the assembly of the *Pregadi* was given greater power, and four more ducal councilors, making six in all, were appointed. Later constitutional changes follow along these same lines. On the one hand, power is taken away from the people as represented in the General Assembly; on the other hand, the influence of the Doge is gradually restricted until he becomes a figurehead, though the pomp and dignity of the office are increased. These changes, however, were made very gradually, and some of the strongest doges ruled during the thirteenth and fourteenth centuries. See DANDALO.

TERRIERS, SPANIELS, ETC.

1. BULL TERRIER, "Woodcock Wonder."
2. AIREDALE TERRIER.
3. ENGLISH BULLDOG, "Katerfelto."
4. POODLE, "Milo Boy."

5. BEAGLE, "Primate."
6. CLUMBER SPANIEL "Medway."
7. IRISH TERRIER.
8. SCOTCH TERRIER, "Adora Alexander."

The people resisted strenuously when the Council attempted to deprive them of the right of electing the Doge. Finally the Council hit upon the expedient of electing the Doge and then presenting him to the people with the following formula: "This is your Doge, if it please you," a formula which was used until 1423. The method of electing the Doge was modified frequently with the purpose of preventing partisanship and corruption. In 1268 the following method was adopted:

The Great Council by lot chose	30	
The 30 were reduced by lot to	9	
The 9 voted for	40	{ with at least 7 votes each
The 40 were reduced by lot to	12	
The 12 voted for	25	{ with at least 9 votes each
The 25 were reduced by lot to	9	
The 9 voted for	45	{ with at least 7 votes each
The 45 were reduced by lot to	11	
The 11 voted for	41	{ with at least 9 votes each
The 41 elected, with a minimum of twenty-five votes, the Doge.		

The power of the Doge was greatly circumscribed, especially after 1229, by making the coronation oath more strict, by the establishment in 1310 of the fearful Council of Ten, and by the appointment of inquisitors to examine in detail all the acts of the deceased Doge. By the coronation oath of Tiepolo, in 1229, he was forbidden to correspond with the Pope, the Emperor, or any other sovereign without the consent of the ducal councilors, and the size of his household was fixed. Loaded down with burdensome conditions and clothed only with empty honors, the office ceased to be sought for. In 1361 the Doge was required to abdicate when asked to do so, but was not allowed to resign of his own accord. A few years later Andrea Contarini was forced to accept the office against his own will, under threat of a confiscation of his property, but in compensation was given a larger household. In 1437 Venice felt the need of a title to the land empire which she had acquired, and the Doge obtained a diploma of investiture from the Emperor, creating him "Duke of Treviso, Feltre, Belluno, Ceneda, Padua, Brescia, Bergamo, Carrara, Soncino, and Peschiera." In spite of this, the Doge had little real power in the last centuries of the republic's existence; the office disappeared with the fall of the republic in 1797.

The republic of Genoa elected, after a victory gained by the party of the people, in 1339, Simone Boccanera for its first Doge. In 1396, when Genoa came (for a short time) under the rule of the French, the office of Doge was suppressed. It was revived in 1528, when a new aristocratic constitution was instituted under the auspices of Andrea Doria. In most respects the office was restricted, as in Venice. In 1797, when Genoa was occupied by the French, the office was abolished. It was reestablished in 1802 for the Ligurian Republic and again abolished in 1805, when the republic came to an end. Consult Brown, *Venice* (New York, 1893); *Studies in the History of Venice*, vol. i (London, 1907); Checchetti, *Il Doge di Venezia* (Venice, 1864); Hazlitt, *The Venetian Republic* (2 vols., London, 1900); Picotti, *La dieta di Mantova e la politica de Veneziani* (Venice, 1912).

DOGE'S PALACE, THE. The residence for four centuries of the dukes (doges) of Venice,

situated on the Piazzetta adjoining the Piazza of St. Mark; founded about 814, and subsequently destroyed and rebuilt five times. The present reconstruction was begun in 1340; the Gothic façade dates from the first half of the fifteenth century. Its architecture makes it one of the most striking buildings in Europe. On the south and west sides a noble arcade resting on 36 columns, surmounted in the second story by a superbly traceried arcade on 71 smaller columns, supports the two upper stories. These form a heavy square mass, relieved by balconies, pointed arches, and surface patterning in light and dark marbles, and the whole is crowned with a battlemented cornice. The Porta della Carta, so called because it was the washroom of the secretaries who prepared the documents (*Carte*) exemplifies the final efflorescence of Gothic art; the Court and the Giants' Staircase, at the head of which the doges were crowned, are among the most perfect early works of the Venetian Renaissance. They are the work of Pietro Lombardi and Antonio Rizzo (1483-90). On the east the palace is connected by the famous Bridge of Sighs with the old prisons. The building is rich in historical memories. It contains the magnificent Sala del Maggior Consiglio, or Great Council Hall, in which the meetings of the Nobili were held; and the Sala della Scrutinio, or Voting Hall, both surrounded with historical paintings; the Archaeological Museum; the famous Bocca di Leone, an orifice opening into the anteroom of the Inquisitors and used to deposit secret information and accusations; torture chambers and dungeons, and the place of execution for political offenders. Many of the most glorious works of the great Venetian triumvirate of painters of the sixteenth century—Titian, Veronese, and Tintoretto—adorn the walls and ceilings of the more important rooms. Consult Hare, *Venice* (several editions.).

DOG FEN'NEL. See FEVERFEW; MAYWEED.

DOGFISH. A popular name for small sharks, apparently because they follow their prey like dogs hunting in packs; also "hound" and "bone-log." It is most commonly given in the United States to *Squalus acanthias*, of the "dogfish" family Squalidæ, of which characterised by a spine before each of the two dorsal fins; spiracles, or spout holes; five gill openings on each side, all before the pectoral fins; no anal fin and no nictitating membrane of the eye. It is oviparous. The body is long and tapering; the head flat; the snout conical, the teeth in both jaws sharp-edged and formed for cutting. It attains a length of 3 to 4 feet and a weight of 10 to 15 pounds. It is abundant on both coasts of the North Atlantic. The dogfish of the Pacific Coast of North America is taken in great numbers for the sake of the oil extracted from its liver. (See Plate of LAMPREYS AND DOGFISH.) The same name is given to the "requiem sharks" (Guloidæ), especially to the smooth hound, or "dog shark" (*Mustelus canis*) of the North Atlantic (see TORP), which resemble the Squalidæ in general form, but have an anal fin and are ovoviviparous; also to the bowfin (q.v.).

DOGGERBANK (Eng., Ger., Dutch *dogger*, sort of Dutch fishing boat + *bank*). An extensive flat sandbank near the middle of the North Sea between England on the west and Denmark on the east, with a maximum breadth of 60 miles and an average breadth of about 40 miles. It stretches northeast and southwest for

a distance of about 200 miles between the limits of lat. 54° 10' and 55° 40' N. and long. 1½° and 5° E. It has in general a depth of less than 120 feet and towards the English coast has little over 50 feet of water. This bank furnishes important codfishing grounds. On the night of Oct. 21, 1904, the Russian Baltic squadron, under Admiral Rozhdestvensky, on its way through the North Sea to the Far East, fired upon a British fishing fleet on the Dogger, killing two men. The incident was finally settled by arbitration, Russia paying damages for loss sustained. The action of the Czar's fleet was due probably to sudden panic.

DOG'GETT, or **DOGGETT**, THOMAS (?-1721). An English comedian and manager. He was born in Dublin. He appeared in 1691 in London at Drury Lane, as Nincompoop in *Love for Money*. In 1695 he first played the part of Ben in Congreve's *Love for Love* with Betterton at Little Lincoln's Inn Fields. The next year he played Hob in his own piece called *The Country Wake*. In 1701 he played Shylock, as a comic part, to Betterton's Bassanio. He became, in 1709, one of the managers of the Haymarket, but left his partners about four years afterward, and later played a few times at Drury Lane. The well-known prize which bears his name, Doggett's Coat and Badge, was founded in 1716 in celebration of the accession of George I. Consult Doran, *Annals of the Stage*, ed. by Lowe (London, 1888), and *Thomas Doggett, Deceased* (ib., 1908).

DOG GRASS. See **COUCH GRASS**.

DOGMA (Lat., from Gk. *δόγμα*, *dogma*, from *δοkein*, *dokein*, to seem). Originally an opinion or proposition, put as a positive assertion, its truth being supposed to have been previously shown. In theology it was understood to signify a doctrine defined by the Church and advanced, not for discussion, but for belief. But as this method of stating truth easily degenerates into the assertion of opinions without ground, and without regard to the aspect they may present to others, *dogma* and *dogmatism* have come in English to be frequently used for assertion without proof.

In continental theology, however, the word is still used without implying any censure, dogmas (Ger. *Do.*) simply doctrines conceived as the Christian Church; and this is the case in our own expression "dogmatic theology," or "dogmatics," which is that branch of theology that treats of the systematic arrangement of the doctrines of Christianity. The first attempt to give a connected view of Christian doctrine was made in the fourth century by Augustine, who in his *Encheiridion* and other works treated of the whole body of doctrine held by the Church, though without any very scientific arrangement. The contributions to dogmatics made in the fifth, sixth, and seventh centuries were mere collections of "sentences." In the East, in the eighth century, the doctrines of the Greek church were treated by John of Damascus in a form already Aristotelian, and his work may be considered the first systematically arranged treatise on dogmatics. His book was as influential in the Greek church as the writings of Augustine in the Latin. The regular systematizing of doctrines began with the Scholastics in the eleventh century. The first cultivators of dogmatic theology among the Scholastics were Hildebert of Tours (died 1133) and Abélard (died 1142), who were fol-

lowed by Petrus Lombardus (died 1164), Alexander of Hales (died 1245), Thomas Aquinas (died 1274), Duns Scotus (died 1308), etc.

The era of the Reformation revived dogmatic controversy, leading it back from Aristotle to biblical theology. But the controversies between the different churches in the seventeenth century and the too great importance attached to confessions of faith, cramped anew its freedom and gave it again a Scholastic turn. (See REFORMATION; GERMAN THEOLOGY.) The theologians of the Roman Catholic church have devoted much labor in modern times to the production of systematic treatises, which usually adhere to the old logical methods of the schoolmen, while taking account of all modern objections to what they consider revealed dogmas. The names of Canisius, Petavius, Thomassin, Bellarmine, Suarez, Liebermann, and Perrone may be mentioned among a host of others in the last three centuries. Pope Leo XIII has consistently held up St. Thomas Aquinas as the norm of modern dogmatic theology and has caused an increased study and use of his works. As a result of the Tractarian movement, much more attention than formerly has been paid to dogmatic theology in the Church of England and its allied bodies. In America systems of doctrine have been produced, among others, by Dwight, Smith, Hodge, Shedd, Strong, Clarke, and Brown. Most of these, however, present doctrine, not as an authoritative dogma, but as a reasoned system of thought. For the history of dogmas, see DEVELOPMENT OF DOCTRINE; CREEDS AND CONFESSIONS.

DOGMATISM. In philosophy, the assumption of metaphysical knowledge without examining the conditions and the limits of the possibility of knowledge. It is the willingness to accept what are supposed to be self-evident truths or the facts of experience without any further ado. All naïve consciousness is in a certain sense dogmatic. The infant apparently does not question the reality of his experiences. But in time the inconsistencies into which he gets by accepting without question everything that comes to him as knowledge call attention to the fact that all is not valid knowledge that seems to be. If, in spite of this fact, a theorist still accepts any as valid in respect to ultimate reality, without first inquiring whether knowledge of such reality is possible, and whether a tenable theory of knowledge validates those judgments, he is a philosophical dogmatist. Philosophical dogmatism may then be defined as the attempt to philosophize without basing one's philosophy on a scientific epistemology. Pre-Kantian philosophy was dogmatic; Kant inaugurated an era of criticism (q.v.) in opposition to this dogmatism. This critical attitude has prevailed till the last decade. Within the last few years there has been a revolt against criticism resulting in some cases in a return to dogmatism. But this recent dogmatism differs from pre-Kantian dogmatism in that it relies more on experience and less on reason. Consult Marvin in *The New Realism* (New York, 1912). See KNOWLEDGE, THEORY OF; CRITICAL PHILOSOPHY; EMPIRICISM; INSTRUMENTALISM; PRAGMATISM; REALISM.

DOG OF MONTARGIS, *môn'târ'zhé'*. See AUBREY DE MONTDIDIER.

DOG'RIBS. A Déné (q.v.) tribe in Canada ranging around Great Slave Lake. See ATHEPASCAN STOCK.

DOGWOOD TREE

COPYRIGHT 1907 BY HENRIETTA T. LEE

DOGWOOD TREE (*Cornus florida*) ; Southern New York, early May.

DOG SALMON, sām'ūn. 1. A salmon (*Oncorhynchus keta*) of the northwestern American coast, which resembles the quinnat, but is much smaller and without spots on the fins. It ascends all streams from San Francisco to Kamchatka, but its flesh is of little value. Native names are hay-ko, le kai, and keta. 2. In

A DOG SALMON.

Alaska, an allied species known as the hump-back salmon (*Oncorhynchus gorbuscha*). (See SALMON.) 3. The adult male of any salmon, when it is ascending a river in the breeding season, or attending upon the females at the spawning grounds. In the course of this duty the fish take no food whatever, and succumb soon after spawning, regardless of the distance or proximity of the sea.

DOG SHARK. See DOGFISH; TOPE.

DOG'S MERCURY. See MERCURY, Dog's.

DOG'S-TAIL GRASS (so called because its spike is fringed only on one side), *Cynosurus*. A genus of grasses having a close spike, each spikelet with two equal glumes and three to five florets. The species, which are not very numerous, are chiefly natives of Europe and Asia; but one only is common and valuable, the crested dog's-tail grass (*Cynosurus cristatus*), which forms an important part of almost all good pastures and is particularly esteemed for sheep pastures and lawns, for the improvement of which it is often sown. It is a perennial grass, growing in tufts 1 or 2 feet high, with many fine root leaves. Its herbage is fine and close, and its deep roots secure it against droughts, which cause many other grasses to wither; but the herbage is not sufficient in quantity to make it desirable for hay. The seeds are small, shining, and yellow, whence the name "goldseed" sometimes given to this grass by farmers. The mature stems of this grass are used in the manufacture of Leghorn hats. It has been sparingly introduced into the United States. It grows best on rich moist soil and, as it endures shade well, is adapted to shaded lawns.

DOG STAR. See SIRIUS.

DOG'S-TOOTH VIOLET. See ERYTHRONTIUM.

DOGTOTH. In architecture a carved ornament frequently occurring in English Gothic work of the late twelfth and early thirteenth centuries, in the form of small square pyramids set at close intervals or even in direct contact in the hollow between two salient moldings, the sides carved like the petals of a flower; called also *pyramid flower*.

DOGUERA. A baboon (*Cynocephalus*, or *Papio*, *doguera*) of Abyssinia, more olive in color than the sacred baboon (see BABOON), but possibly a variety of it.

DOGWATCH. The two short watches of two hours each, from 4 to 6 p.m. and 6 to 8 p.m. These watches were introduced for the purpose of securing a change of watch each day for the watch officers. As it makes 7 watches per lay instead of 6, it causes officers to have dif-

ferent watches every day, if there are less than 7—and the number rarely exceeds 5—except on large men-of-war or for a few days at a time. See WATCH.

DOG WHEELK. See WHEELK.

DOGWOOD. A name given to some of the shrubby and aborescent species of the genus *Cornus*. There are about 25 species indigenous to Europe, Asia, and North America, most of which are shrubs, although a few become trees. The common dogwood (*Cornus sanguinea*) of Europe is a shrub 12 to 18 feet high. As with all the larger shrubs and trees of the genus, the wood is hard and the bark bitter. The fruit is small, and in France an oil used in soap-making is expressed from it. The Cornelian cherry (*Cornus mas*), also a native of Europe, yields an edible fruit, which is sometimes used for preserves. *Cornus kousa* and *Cornus capitata* are trees in the eastern part of Asia, and *Cornus florida*, *Cornus alternifolia*, and *Cornus nuttallii* in the United States. The last-named species is the largest of the genus, trees often reaching a height of 70 to 90 feet and a diameter of 2 feet. It is confined to the Pacific coast region from British Columbia southward. The common tree species in the United States is *Cornus florida*, which is found from Massachusetts to Texas. It is a small tree rarely more than 30 feet tall, and is well known on account of its four, sometimes more, white or pink showy bracts ("flowers," which surround the inconspicuous greenish-yellow true flowers). In *Cornus nuttallii* the bracts are a deep pink and are 4 or 5 inches across, making the tree a very striking object in the forest. The berries are red and remain on the trees during most of the winter. The wood is white, hard, and fine-grained, and is much used for inlaying, turning, etc. The bark of *Cornus florida* contains a bitter tonic principle somewhat resembling that found in cinchona, like which it has been used to some extent in the treatment of fevers. Other species also contain it, but in smaller quantities. Two dwarf herbaceous species are common at high latitudes, *Cornus canadensis* and *Cornus suecica*. They are but a few inches high, have small, white-bracted clusters of flowers and red berries, often called bunchberries, from their habit of growth. The shrubby species are common along watercourses and do not have bracts to their flowers. Some of them are quite showy when in flower, and also in winter, when their stems are bright red. The autumn coloring of all the species is very striking, red colors prevailing. In the West Indies *Piscidia erythrina*, a leguminous tree, is known as dogwood. Its timber is hard and very durable. The bark contains a narcotic substance frequently used for stupefying fish, and as an anodyne in medicine. Poison dogwood—or poison sumac, as it is more properly called—is *Rhus vernia*, a species nearly related to and greatly resembling the *Rhus* of Japan, one of the trees from which, through the action of the lac insect (*Casteria lacca*), the lac of commerce is derived. See Colored Plate of POISONOUS PLANTS. See CORNELL.

DOHERTY, dōh'ēr-tī, CHARLES JOSEPH (1855-). A Canadian lawyer and statesman. He was born at Montreal and was educated at the St. Mary's College and McGill University, where he graduated in 1876. He chose the legal profession, was called to the bar in 1877, and soon gained a large practice.

In 1883 he was appointed a member of the Royal Commission to investigate the working of the Protestant and Catholic school boards, Montreal. He afterward became professor of civil and international law in McGill University. In 1891-1906 he was a puisne judge of the Superior Court of Quebec. On retiring from that position he resumed practice. In 1881 and 1886 he was an unsuccessful Conservative candidate for the House of Commons. In 1908 he was elected for a Montreal constituency and actively supported Robert Laird Borden (q.v.), the Conservative leader, in opposing the Liberal policy of reciprocity with the United States. After the defeat of the Laurier administration, in 1911, Doherty was appointed Minister of Justice in Premier Borden's cabinet.

DOHERTY, HENRY LATHAM (1870-). An American operator of gas and electric companies, born at Columbus, Ohio. He became an office boy for the Columbus Gas Company when only 12 years old, advanced rapidly through various positions, and between 1890 and 1905 was engineer or manager of gas, electric, or traction companies in 29 cities. In 1905 he organized Henry L. Doherty & Co., of New York City, bankers and operators of public-utility corporations. He patented several combustion processes and various pieces of apparatus, was awarded the first Beall gold medal in 1898 by the American Gas Light Association for a paper on "Gas for Fuel," and was president of the Northwestern Electric Association (1899), the National Electric Light Association (1901), and the Ohio Gas Light Association (1902), and vice president of the American Gas Institute (1908).

DOHERTY, ROBERT REMINGTON (1848-). An American theologian and author. He was educated at Dickinson College, Pa., and at Grant University, Tenn. He wrote on religious topics, especially for Sunday schools. His principal works include: *A Guide to the Study of the International Lessons*, an annual publication (jointly with Dr. J. L. Hurlbut and Dr. T. B. Neely, 1891-1901); *Representative Methodists* (1888).

DOHM, dōm, ERNST (1819-83). A German humorist. He was born at Breslau and studied theology and philosophy at Berlin and Halle. He was editor of *Kladderadatsch*, one of the most humorous political publications of Germany, from 1849 until his death and took high rank as a master of political satire. He translated the *Fables* of Lafontaine into German (illustrated by Gustave Doré, 1876-77) and published poems, comedies, and farces, of which *Das erste Debit* (3d ed., 1860) was probably the most popular.

DOHNANYI, dō'nōn-yé, ERNST VON (1877-). A Hungarian pianist and composer, born in Pressburg. He studied at the Royal Conservatory in Budapest (1894-97), where several of his compositions received prizes. For two months during the summer of 1897 he studied with D'Albert, and in the autumn of the same year began a successful concert tour of the principal cities of Germany, and England. Beginning in March, 1900, he made a successful concert tour in America and returned in October, 1900, for another tour. He played, with the Boston Symphony Orchestra, his pianoforte concerto in E minor (Rosendorf prize composition, Vienna, March, 1899) and composed, besides that work, a second piano

concerto in Db, an overture *zriny*, a concert-stück for 'cello and orchestra, piano pieces, chamber music, and two symphonies, which show a decided talent for the larger forms. A comic opera, *Tante Simona*, was produced with success in Berlin (1913).

DOHRN, dōrn, ANTON (1840-1909). A German zoölogist, son of Karl August Dohrn, born in Stettin. He studied the natural sciences under Haeckel in Jena, where he subsequently became privatdocent. He was also for several years interested in the investigation of marine animals, especially crustaceans, and made excursions to the coast of England and to the Mediterranean for the purpose of studying them. In 1870 he founded the Zoölogical Station at Naples, the first and most important institution of its kind. (See ZOÖLOGICAL STATION.) He has written *Der Ursprung der Wirbelthiere* (1875); *Studien zur Urgeschichte des Wirbelthierkörpers* (1882).

DOHRN, KARL AUGUST (1806-92). A German entomologist. He was born in Stettin, educated in Berlin, and traveled extensively. In 1842 he became president of the Entomological Society of Stettin (the first to be established in Germany) and editor of the *Entomologische Zeitung*. From 1846 to 1866 he was engaged in the publication of the *Linnae Entomologia*, a work of sixteen volumes. He was one of the most distinguished coleopterists of his time.

DOK'ANA (Gk. τὰ δόκανα, from δόκος, dokos, beam). A rude Spartan symbol formed by two upright beams crossed by other beams. It was of very ancient origin, and was probably the representation of the Dioscuri, considered as gods of war, which the Spartan generals took with them in the field.

DOKO, dō'kō. A term applied generally to dwarfish tribes of Central Africa; pygmy. Consult Keane, *Man, Past and Present* (Cambridge, 1899).

DOL'ABELLA, PUBLIUS CORNELIUS (c.70-43 B.C.). A Roman of patrician family, and of profligate character. Though involved in criminal charges, he was defended and protected by Cicero; and in 49 B.C. he put away his wife Fabia that he might sue for the hand of Cicero's daughter Tullia, whom he married, notwithstanding the orator's opposition. The recklessness of Dolabella plunged him always deeper into debt, until in a short time, driven from Rome by the demands of his creditors, he took refuge in Cæsar's camp and was assigned to the command of a fleet. He took part, but without distinction, in the battle of Pharsalus, and then returned to Rome, hoping to be enriched from the spoils of Cæsar's victories, but in this he was disappointed. Accordingly he had himself adopted into a plebeian family and secured the tribuneship, when he audaciously proposed a law that all debts should be legally canceled; this proposal led to long and bloody contests. Cæsar gave him appointments in his African and Spanish campaigns. On the death of the dictator Dolabella seized the consular insignia and allied himself with the conspirators. He was, however, soon won over by Antonius, who made him governor of Syria. He caused at Smyrna the death of the proconsul, C. Trebonius, who had withstood the extortion which marked his coming to his province. At length, when Cassius besieged him in Laodicea, to avoid capture he ordered a soldier to kill him (43 B.C.).

CARLO DOLCI
"THE MAGDALEN," FROM THE PAINTING IN THE UFFIZI GALLERY, FLORENCE

DOLA'BRA (Lat., from *dolare*, to hew). The Roman name for an implement used by soldiers in cutting wood, building palisades, or tearing down walls, or as a battle-axe; by the husbandmen for breaking up the soil or trimming trees; and, finally, at sacrifices. It seems to have had a long handle of wood, to which was attached a head having a sharp hatchet blade on one side and a slightly bent pick on the other. A smaller form was called *dolabella*.

DOLBEAR, dōl'bēr, AMOS EMERSON (1837-1910). An American inventor and teacher. He was born in Norwich, Conn., and graduated from the Ohio Wesleyan University in 1866. In 1874 he became professor of physics at Tufts College (Mass.). He made several important inventions and researches in connection with the writing telegraph (1864), the electric gyroscope (1867), the magnetophone (1876), the static telephone (1879), wireless telegraphy (1881), and photographing with electric waves (1893). In 1873 he announced the convertibility of sound into electricity. His works include: *The Art of Projecting* (1876; 1888); *Matter, Ether, and Motion* (1892); *The Machinery of the Universe* (1897).

DOLCE, dōl'chā, LODOVICO (1508-66). An Italian author, born in Venice. He is a typical representative of the diffuse culture of the Italian Renaissance. He was prolific as a writer of comedy of classic character, of translations (especially of Horace), or criticism and philology (*Osservazioni nella volgar lingua*), of history and poetry. Consult Salza, *Delle commedie di L. D.* (Melfi, 1899).

DOLCI, dōl'chē, CARLO (1616-86). A Florentine religious and portrait painter. He was born May 25, 1616, and at the age of 14 painted a portrait of himself, especially good in color, now in the Pitti Gallery. Although a pupil of Jacopo Vignali (q.v.), he did not follow the general tendency of the Mannerists, but finished his works very carefully. He confined himself chiefly to small canvases of a religious nature, usually representing a single figure, half figure, or head. His colors are not without harmony, but their effect is marred by heavy, dark shadows, and the surface of his pictures is almost as smooth as porcelain. His work is chiefly characterized by its religious sentimentality. Among his best paintings are his own portrait at the age of 56 and that of the "Archduchess Claudia," both in the Uffizi (Florence); "Christ Blessing the Bread and Wine," Cathedral of Pistoja; "Ecce Homo" in the Pitti; "St. Cecilia," Dresden Gallery; the famous "Magdalen" at Munich, and many other representations of this last subject. His works may be best studied in the Uffizi and Pitti galleries and in the Corsini Palace in Florence. One of his few pictures painted life-size, the "Virgin Appearing to St. Louis, Bishop of Toulouse" (Uffizi), shows his incapability of treating larger subjects. His works were often repeated by himself, and especially by his daughter and pupil Agnese, and have been frequently engraved. He died in Florence, Jan. 17, 1686. Consult Baldinucci, *Notizie del professori del disegno* (Florence, 1728-1846), and special edition of the *Life of Dolci* (ib., 1886). The latest publication, Hay, *Carlo Dolci* (London, 1908), is full of errors.

DOL'CINITES, or **DUL'CINISTS**. The followers of Dolcino. See APOSTOLIC BRETHREN.

DOLDRUMS (apparently a quasi-Lat. form

of dialectic Eng. *dold*, *dolt*, really p.p. of *dull*, to stupefy, from *dull*, AS., OS., *dol*, Ger. *toll*, stupid, mad). A name given by sailors to that part of the ocean near the equator in which calms and light baffling winds prevail with hot, sultry air, local squalls, thunder, and rain. In the doldrums sailing vessels beat about for weeks and they were formerly the dread of those vessels that had to cross the equator. The sailing directions and charts published by Maury were the first to give comprehensive directions for avoiding those parts of the ocean most troubled by the doldrums. The doldrums proper oscillate north and south of the equator with the season of the year. They lie farthest north in July, August, and September, and farther south in January, February, and March. In the Atlantic Ocean in February, the region having most characteristic doldrums extends between the equator and lat. 5° N. and between long. 50° and 30° W., whereas in August it extends between lat. 5° and 10° N. and long. 30° and 45° W. In the Pacific Ocean, in January, the doldrum region extends, with but few interruptions, between the equator and lat. 15° S. and from long. 130° E. eastward to long. 145° W. In July it extends over two regions somewhat separated from each other, viz., from lat. 10° N. to lat. 10° S., and from long. 130° to 165° E., and again from long. 145° to about 80° W., and from lat. 5° to 15° N. The region of the doldrums is characterized by the highest temperatures and moistures, coupled with the feeblest winds that occur anywhere on the ocean; the ocean surface in these regions is of a glassy smoothness, often bearing a thin layer of oil and waste left by passing vessels and floating for a long time on the surface. An irruption of cool air into the doldrums has been suggested as the initial step in the formation of a rainy region in which develop the West Indian hurricanes. Although there is but little horizontal motion of the air within the doldrums, yet there appears to be considerable vertical motion. The doldrum region lies between the region of northeast and southeast trade winds and is the apparent starting point of the great upper currents that are supposed to flow from the equatorial regions north and south towards either pole.

DÔLE, dōl. The capital of an arrondissement in the Department of Jura, France, 25 miles southeast of Dijon (Map: France, N., L 5). It is picturesquely situated on a vine-clad slope rising from the right bank of the river Doubs and the Rhône-Rhône Canal and overlooking the forest of Chaux. The surrounding country is laid out in gardens and promenades. Its principal buildings are the church of the Cordeliers; church of Notre Dame, a Gothic edifice of the sixteenth century; the college, with an art gallery, founded by the Jesuits; the Hôtel Dieu; the barracks; the Palais de Justice, occupying a fourteenth-century convent; and the Tower of Vergy, now used as a prison. Public institutions include a college, an agricultural society, a school of design, an art gallery, and a public library of 40,000 volumes. The chief manufactures are hosiery, tiles, pottery, chemical products, and beer; there are also iron-smelting furnaces, foundries, machine shops, distilleries, and flour mills. The city carries on some trade in corn, wine, wood, marble, and iron. Pop., 1901, 14,627; 1911, 16,294. Dôle was a Roman station and garrison town. It

belonged to the dukes of Burgundy and resisted with great spirit the efforts of Louis XI to annex it in 1479. It became the capital of Franche-Comté at the beginning of the fifteenth century, and part of France in 1678. It is the birth-place of Pasteur.

DOLE, CHARLES FLETCHER (1845-). A Unitarian clergyman. He was born at Brewer, Me., and graduated at Harvard in 1868 and at Andover Theological Seminary in 1872. He was professor of Greek at the University of Vermont in 1873, and in 1876, after two years as pastor of the Plymouth Church of Portland, Me., became minister of the First Congregational Church of Jamaica Plain, Boston. His works include: *Early Hebrew Stories* (1886); *The Golden Rule in Business* (1895); *A Catechism of Liberal Faith* (1895); *The Coming People* (1897); *The Theology of Civilization* (1899); *The Religion of a Gentleman* (1900); *The American Citizen* (1902); *The Hope of Immortality* (1906); *The Ethics of Progress* (1906); *The Coming Religion* (1910); *The Burden of Poverty* (1912).

DOLE, NATHAN HASKELL (1852-). An American editor, translator, and author, born at Chelsea, Mass. He graduated at Harvard University in 1874 and was for some time active as a writer and journalist in Philadelphia, New York, and Boston. He translated, notably: many of the works of Tolstoi, and books of other Russians; novels of the Spaniard Valdés (1886-90); a variety of works from the French and Italian. His editorial labors, varied and extensive, include: *Omar Khayyám* (1896); *Tolstoi's Collected Works* (20 vols., 1899); *Poetical Works of Keats and Shelley* (1905); *Vocations* (10 vols., with William DeWitt Hyde and Caroline Ticknor, 1909-10). Among his original writings are: *A Score of Famous Composers* (1891); *The Hawthorne Tree and Other Poems* (1895); *Joseph Jefferson at Home* (1898); *Life of Count Tolstoi* (1911); *The Spell of Switzerland* (1913).

DOLE, SANFORD BALLARD (1844-). An Hawaiian statesman. He was born in Honolulu, the son of American missionaries, graduated at Williams College, and was admitted to the bar in Boston. He was judge of the Supreme Court of Hawaii from 1887 to 1893. On the overthrow of the kingdom in 1893 he became President of the provisional government and in 1894 was elected President of the newly established Hawaiian Republic, to hold office until 1901. President Cleveland's intention of restoring constitutional authority to Queen Liliuokalani was defeated by the action of President Dole. In 1898 he was appointed on the commission for recommending legislation regarding Hawaii to the Congress of the United States, and in 1900, after the annexation, he was Governor of the Territory of Hawaii until 1904, when he was appointed United States Judge of the Territory.

DOL'ERITE. See BASALT.

DOLES, FUNERAL. See MORTUARY CUSTOMS.

DOLET, dō'lā', ETIENNE (1509-46). A noted French scholar and printer. The legend which represents him as the illegitimate son of Francis I is absolutely without foundation, since the future King of France was not yet 15 years of age when Dolet was born. He was born at Orléans, studied in Paris, Padua, and Venice, where he became secretary to Jean de Langeac, Ambassador of France to the Republic

of Venice. At the early age of 21 he was already planning his great work on the Latin language, and with that end in view he followed the courses on Lucretius and Cicero given at Padua by Egnatius and Simon de Villeneuve. Returning to France in 1530, he began the study of law at Toulouse in 1532, but, becoming involved in a controversy with the authorities regarding the suppression of students' societies, he was imprisoned. Fearing the sentence of death for his utterances on religion, he invoked the intervention of Jean de Pins, Bishop of Rieux, who succeeded in persuading the authorities of the Parlement of Toulouse to limit his punishment to banishment. Arriving at Lyons on Aug. 1, 1534, he became corrector to the presses of the famous printer Sébastien Gryphe. At the age of 25 he already enjoyed great renown as a scholar and Latin poet. In 1535 he undertook the defense of the Ciceronians against Erasmus and others, publishing his *Dialogue on the Imitation of Cicero* (*Dialogus de imitatione Ciceroniana adversum Desiderium Erasmus Roterodamum pro Christoforo Longolio*), and in 1536 issued the first folio volume of his master work, the *Commentaries on the Latin Language* (*Commentariorum Linguae Latinae*). The second volume appeared in 1538, but the last was never published on account of the premature death of the author. On Dec. 31, 1536, Dolet was attacked in the streets of Lyons by a young painter named Jehan Compaign, whom he killed in self-defense. He escaped from Lyons and betook himself to Paris, where he sought the assistance of Pierre Duchâtel, Bishop of Tulle, and Margaret of Navarre, sister of King Francis. Through their efforts a royal pardon was secured for him on the 19th of February following. Returning to Lyons, he was nevertheless imprisoned for a month until the order of liberation was given on the 21st of April. The following year (1538) he secured permission from Francis I to print his own writings for 10 years and established himself at once as a printer at Lyons, issuing important scholarly works in considerable numbers. In 1538 he married Louise Giraud, and the next year he celebrated the birth of his son Claude in a long Latin poem, translated almost simultaneously into French, entitled *Genethliacum Claudii Doleti*. The astonishing prosperity of his presses—in 1542 alone he published almost 40 works—won him the antipathy of his competitors, from which he suffered keenly at times. Probably at their instigation he was arrested in July, 1542, for having translated the Bible into French, as well as for his versification of the Credo, in which he had suppressed the words *communione sanctorum* and had substituted *habeo fidem* for *credo*. His friend Duchâtel again came to his rescue, and succeeded in having him released in October, 1543. Notwithstanding this, the persecutions of the unfortunate printer did not cease, and he was again arrested by the order of the Sorbonne, this time for having mistranslated a passage of the *Axiachus*, then falsely attributed to Plato. He was accordingly taken to Paris, and on Aug. 3, 1546, was branded, tortured, strangled, and burned as an atheist. It was said that he repented in his last moments, but there is no proof to substantiate this assertion. He was also considered by some as a Huguenot martyr, but without any foundation, for Calvin accused him of heresy. The minutes of

Dolet's trial were printed by Taillandier in 1836 (*Procès d'Etienne Dolet*) from the registers of the Parlement of Paris. On the first Sunday of August of each year the anticlerical party is accustomed to hold a demonstration before the statue of Dolet, which is located in the Place Maubert, where he was burned. Consult: Boulmier, *Etienne Dolet* (Paris, 1875); R. C. Christie, *Etienne Dolet, the Martyr of the Renaissance* (London, 1899); Galtier, *Etienne Dolet* (Paris, 1907); Firmin-Didot, *Essai sur la Typographie* (ib., 1852); Baudrier, *Bibliographie lyonnaise*, vol. viii (Lyons, 1910).

DOLGELLY, döl-géth'lä (Welsh, dale of hazels). A market town and the capital of Merionethshire, North Wales, on the Wnion, about 60 miles southwest of Chester (Map: Wales, C 4). It lies in a rich and picturesque valley, at the foot of Cader Idris, and during the summer months is much frequented by English and foreign tourists. It is celebrated as the place where Owen Glendower held his Parliament in 1404 and signed his treaty with Charles VI of France. It has manufactures of coarse woollens and flannels. Pop., 1901, 2437; 1911, 2160.

DOLGEVILLE. A village in Fulton and Herkimer counties, N. Y., 30 miles east of Utica, on the New York Central Railroad, and on East Canada Creek, which develops considerable water power (Map: New York, F 4). It contains two fine natural parks and a public library. Dolgeville is the centre of the felt shoe industry, which originated here, and has a large piano-sounding-board factory, flour mills, and a tannery. The water works are owned by the village. Pop., 1900, 1915; 1910, 2685.

DOLGORUKOVA, döl'gò-ròò'kò-vá, EKATERINA MIKHAILOVNA, PRINCESS YUREVSKAYA (1846-). The favorite of the Russian Czar Alexander II, who contracted a morganatic marriage with her in July, 1880, after the death of his wife. She bore him a son, Prince Georgiy Yurevsky (1873), at present in the Russian navy, and two daughters. After the assassination of the Czar she removed to Switzerland, and in 1892 published at Geneva, under the pen name of Victor Laferté, *Alexandre II, Détails inédits sur sa vie intime et sa mort*.

DOLGORUKY, döl'gò-ròò'kè, PETER VLADIMIROVITCH (1807-68). A Russian author, born in Moscow. His *Notice sur les principales familles de la Russie* (published under the name of D'Almagro, 1843) caused his temporary banishment by Czar Nicholas I. This work formed the basis for his *Russian Genealogy* (4 vols.) published under his own name at St. Peter-burg in 1854. Upon the appearance of his *La vérité sur la Russie* (1860) he was finally exiled from Russia for life. His *Mémoires* (1867-71) contain much of interest regarding many notable personages of his day.

DOLICHOCEPHALY, döl'í-kò-séf'à-lí. See ANTHROPOMETRY.

DOLICHOS, döl'í-kòs (Neo-Lat., from Gk. δολιχός, *dolichos*, long, on account of the long pods). A genus of plants of the family Leguminosæ, closely allied to *Phaseolus* (see KIDNEY BEAN), from which it is distinguished by the extension of the base of the standard so as to embrace the wings of the corolla at their base. The genus includes a considerable number of species—some shrubby, some annual, and some perennial herbaceous plants. Some have beautiful flowers, and some of the herbaceous species

are cultivated on account of their seeds, which afford a kind of bean; or of their young pods, which, like those of the kidney bean, are boiled for the table. The more important species are *Dolichos lablab*, a native of India and Egypt; *Dolichos lubia*, a native of Egypt; *Dolichos sesquipedalis*, a native of America; and *Dolichos biflora* (horse gram), native in India; *Dolichos sphaerospermus* (calavana, or dark-eyed pea), a native of the West Indies. In the climate of Great Britain even the most hardy kinds require the aid of a little artificial heat, and they are reckoned inferior to other kinds of beans or garden vegetables of easier cultivation. The soy bean, *Vigna sinensis* or *Soja hispida*, was formerly referred to this genus. The well-known Japanese sauce or ketchup called soy is made from the soy bean. Allied to *Dolichos* is the genus *Canavalia*, to which belong the sword and Jack beans of India. *Canavalia ensiformis* (Jack bean), the commonly cultivated species, has pods about a foot long with white seeds. The sword bean is *Canavalia gladiata*, and most varieties have red seeds. Another allied genus is *Psophocarpus*. The seeds of *Dolichos tetragonolobus* are used in the Mauritius as beans are in America, and its pods and tuberous roots are common Indian esculents. Some species of *Pachyrhizus*, also an allied genus, are remarkable for their tuberous roots, as *Pachyrhizus angulatus*, a native of India, now cultivated in South America and other warm countries for its pleasant, turnip-like tubers; and *Phaseolus trilobus*, which has tubers 2 feet long and nearly cylindrical, much used as a boiled vegetable in China and Cochin-China. See BEAN.

DOLICHOS. See OLYMPIC GAMES.

DOLIUM (Lat., large jar). A genus of gastropod mollusks. See TUN SHELL.

DOLLUM. See VASE.

DOLL (probably from *Doll*, abbreviation of *Dorothy*). A figur. . . . a baby, which has always been a . . . for girls. Dolls have been used from the earliest times and among all nations, barbarous as well as civilized, because such tastes and desires spring from that love of nursing and fondling infants implanted by nature in the female character. The manufacture of dolls is and has always been an industry carried on in the rural districts of continental Europe, chiefly by the peasants in their homes. Factories for the manufacture of dolls have been introduced into England and America, but the extreme cheapness of peasant labor and the wonderful skill acquired by successive generations in the art of doll making still enable this hand-made product to compete successfully with the output of the factory. As in the case of most other toys, dolls were at one time imported into Great Britain chiefly from the Netherlands, and hence not an unusual name for a doll was "a Flanders baby." These old Flemish or Dutch dolls were made of wood, with neatly formed faces and flashy dresses, the cheaper kinds having slender wooden legs. Most of the dolls made about 1860 were the long, slender, kid or cloth bodied dolls, with heads of papier-maché or china. Next came the beautiful wax dolls, with natural ringlets, eyes that open and shut, and apparatus inside by which they could be made to squeak and sometimes say "Papa" and "Mamma."

These dolls, though very beautiful, were both expensive and perishable and are no longer manufactured. Later came the wooden-bodied,

jointed dolls. These were invented by a Frenchman called Jumeau and for a time were made wholly in France; but a jointed doll equally good, though less costly, is made in Germany. China and bisque heads of dolls are made in little village factories in continental Europe, the manufacture being limited by the village authorities on account of the smoke nuisance which it creates. Papier-maché and other composition heads are usually molded at home. In making dolls the work is divided among the members of the household, the father molding the different parts of the doll, the mother painting them and making the wigs, while the children put the parts together. After completion the dolls are taken to a general collecting house.

The manufacture of rubber dolls is a branch of the industry which is chiefly carried on in large factories. A development is the modern rag baby, a doll made from printed cloth and stuffed into the well-rounded form of a baby. This form of doll, printed in bright colors, is largely made in America. In part the place of dolls was at one time taken by figures of animals made from stuffed plush in the form of so-called "Teddy-bears," which at one time enjoyed a vogue in the United States. Dolls follow various fashions, and one form or design may have its vogue only to be supplanted as another fancy may dictate.

DOLLAR. The unit of value in the monetary systems of the United States and Canada. The name itself is derived from Joachimsthal, in Bohemia, where the counts of Schlick in the fifteenth century struck large coins of silver from the metal found in the neighborhood. These were known as *Joachimsthaler*, or, by abbreviation, *thaler*, from which, through the Low German *daler*, the word "dollar" is derived.

Among the multitude of coins which prevailed before the nineteenth century certain issues came to be regarded as standard by reason of the excellence of their manufacture and became international coins of wide circulation. It was thus that a valley in the recesses of the Bohemian mountains gave the name to the monetary unit of Prussia before the establishment of the German Empire, and to that of the United States, Canada, Mexico, and other countries. Somewhat similar is the derivation of the term "florin," familiar in the Netherlands and Austria, and represented in the English coinage, from coins manufactured in the Middle Ages in Florence.

The American dollar, established by the Coinage Act of 1792, was taken from the Spanish dollar in circulation in the Colonies, corresponding to the average weight of the dollar, as slightly less than the legal weight. While the dollar, since 1792, has been the unit of value in the United States, it was, prior to 1873, but little represented by coins of this denomination. The silver dollar, by the Act of 1792, weighed 416 grains and had a fineness of .8924. This weight was changed by the Act of Jan. 18, 1837, to 412.5 grains, .900 fine, at which it still remains. Under the Act of 1873 *trade dollars*, weighing 420 grains each, of limited legal tender, were coined, in order to facilitate trade with China and Japan. Prior to 1873 only 8,031,238 dollars were coined. Large amounts of the half-dollars which were then exactly half the size of the dollar, were, however, coined. Further coinage of the silver dollar was author-

ized by the acts of Feb. 28, 1878, and July 14, 1890. Gold dollars, weighing 25.8 grains, with a fineness of .900, were authorized to be coined by the Act of March 3, 1849, and over 19,000,000 were thus coined before the coinage was discontinued (Sept. 26, 1890). By the Act of March 14, 1900, the gold dollar was declared to be the standard of value in the United States, but no provision was made for the issue of a coin corresponding to the unit. See MONEY.

DOL'ARDEE' (probably from *dollar*, on account of the color). A local name, in Kentucky, for the blue sunfish (*Lepomis pallidus*). See SUNFISH; and Plate of DARTERS and SUNFISH.

DOLLARFISH (so called on account of the color and shape). A local name in Maine for the butterfish (*Stromateus triacanthus*).

DOLLART, *dol'ärt*. A shallow, nearly landlocked inlet of the North Sea at the mouth of the river Ems, between the Prussian Province of Hanover and the Dutch Province of

(Map: Netherlands, F 1). It is about 7 miles in length by 7 in breadth and was formed by inundations of the sea, the first of which took place in the latter half of the thirteenth century and the last in the sixteenth century. By these watery inroads a large number of villages were destroyed and thousands of persons perished. A part of the land has been reclaimed, especially on the Dutch shore.

DÖLLINGER, *döl'ling-ër*, JOHANN JOSEPH IGNAZ VON (1799-1890). A distinguished German Roman Catholic historian. He was born at Würzburg, Feb. 28, 1799. He was educated there and at the University of Würzburg, where his father was professor of anatomy and physiology. He was ordained a priest in 1822. In 1823 he became a teacher at Aschaffenburg; in 1826, professor of church history and ecclesiastical jurisprudence in the newly established University of Munich, and began an extraordinary career as historian, publicist, disputant, and councilor. His first book, *Die Lehre von der Eucharistie in den ersten drei Jahrhunderten* (1826), was written at Aschaffenburg. In 1828 he published a history of the Reformation as the continuation of Hortig's *Handbuch der Kirchengeschichte*. In 1832 he was appointed *defensor matrimonii*. (See DEFENDER OF THE MARRIAGE TIE.) In 1833-35 he published a *Geschichte der christlichen Kirche*, and in 1836-38 the *Lehrbuch der Kirchengeschichte*. Neither of these works was carried to completion; they are combined in the English translation, *A History of the Church* (1840-42). In his next work, *Die Reformation, ihre innere Entwicklung und ihre Wirkungen im Umfange des lutherischen Bekenntnisses* (1846-48), he gathered together all the material he could find unfavorable to the Reformation in his work. *Luther, eine Skizze* (1851), also belongs to this period. For a time he undertook the duties of the chair of dogmatic theology and lectured on "The Philosophy of Religion," on "Symbolism," and on "Patristic Literature." He was a frequent contributor to the *Historisch-politische Blätter* and published several pamphlets on subjects of occasional interest. He was one of the chief contributors to the first edition of Wetzlar and Welte's *Kirchen-Lexicon*, in which his articles on Luther, on Bossuet, and on Duns Scotus attracted much attention. In 1845 he was chosen to represent the University of Munich in the Bavarian Chamber; but, being deprived of his

professorship in 1847, he lost his seat. In the Parliament of Frankfurt in 1848-49 he was recognized as the leader of the Roman Catholic party and fought for the unconditional freedom and independence of the church. In 1849 he was restored to his professorship and also to his place in the Bavarian Chamber, which he held until 1852. Up to this time Dr. Döllinger had been an ardent defender of Catholicity and a bitter opponent of Protestantism. From now on, however, influenced by his historical studies, his attitude began to change and tended more to liberalism. This change dates particularly from a visit to Rome in 1852. Works in which it is evident are: *Hippolytus und Kallistus, oder die römische Kirche in der ersten Hälfte des dritten Jahrhunderts* (1853); *Heidenthum und Judenthum, Vorhalle zur Geschichte des Christenthums* (1857; Eng. trans., *The Gentile and the Jew in the Courts of the Temple of Christ*, 1862), a masterly survey of the condition of the world at the birth of Jesus; *Christenthum und Kirche in der Zeit der Grundlegung* (1860). In 1861 Dr. Döllinger delivered two addresses at Munich which were republished as hostile to the temporal sovereignty of the Pope and brought upon him much criticism. To explain and justify his position he published *Kirche und Kirchen, Papstthum und Kirchenstaat* (1861), a comparative survey of the condition of the non-Catholic communions and of the church, and also a résumé of the history and condition of the Papal States, while the temporal sovereignty was the means providentially established for maintaining the spiritual independence of the papacy, yet it was by no means essential, that the papacy long existed without it, and that, even if it were overthrown, Providence would devise other means of attaining the same end. The second part was a criticism of the administration of the Papal States, which gave dissatisfaction to the authorities, as being, though well meant, inopportune and therefore unfriendly. *Die Papstfabeln des Mittelalters* (1863), and an address delivered at Munich the same year, *Vergangenheit und Gegenwart der katholischen Theologie*, were no more acceptable. Similar feelings were aroused by the part taken by Dr. Döllinger in reference to the "Catholic Union." But his ability and learning were unquestioned, and his influence, especially at home, was very great until the approach of the time for opening the Vatican Council. It was understood that the doctrine of the infallibility of the Pope would be a subject of discussion, and Dr. Döllinger was active in organizing opposition. Assisted by his colleague, Friedrich, and others, he wrote articles and letters on the subject for the Augsburg *Allgemeine Zeitung*, which were afterwards collected in book form: *Der Papst und das Konzil* (1869, under the pseudonym Janus), and *Briefe vom Konzil* (1870, under the name Quirinus). On the publication of the decree of the council defining the infallibility of the Pope in all doctrinal teachings on faith and morals addressed *ex cathedra* to the universal Church, Dr. Döllinger refused to accept the doctrine. In August, 1870, he presided over a gathering of theologians at Nuremberg which publicly repudiated the doctrine and formed the germ of the Old Catholic movement. In the organization of the Old Catholic church, however, he took no active part. He was excommunicated by the Archbishop of Munich in April, 1871.

While the sentence was pending, he was elected rector of the University of Munich by a large majority of votes, and after it was pronounced he received honorary degrees from the universities of Oxford and Edinburgh, and was decorated by the King of Bavaria and the Emperor of Germany. Although he ceased to teach theology, he continued to lecture on ecclesiastical history and related subjects. His literary activity was little diminished during this stormy period of his life. Among his later works may be mentioned: *Sammlung von Urkunden zur Geschichte des Konzils von Trient* (1876); *Akademische Vorträge* (1888-91); *Beiträge zur Sektengeschichte des Mittelalters* (1890); *Briefe und Erklärungen über die vatikanischen Dekrete* (1890); *Kleinere Schriften* (1890). With Professor Reusch he reprinted the autobiography of Bellarmine (1887), and prepared a history of recent Roman Catholic ethical discussion as a thrust at the Jesuits, *Geschichte der Moralstreitigkeiten in der römisch-katholischen Kirche seit dem XVI Jahrhundert* (1890). Among his works translated into English are: *Declarations and Letters on the Vatican Decrees*; *First Ages of Christianity*; *Jew and Gentile in the Courts of the Temple of Christ*; *Hippolytus und Kallistus*. He died at Munich, Jan. 10, 1890. Consult: Kobell, *Ignaz von Döllinger, Erinnerungen* (Munich, 1891); Michael, *Ignaz von Döllinger, eine Charakteristik* (Innsbruck, 1893); and particularly the life by Friedrich (Munich, 1899-1901). See OLD CATHOLICS.

DOLLIVER, JONATHAN PRENTISS (1858-1910). An American legislator, born in Preston Co., W. Va. After graduating from the University of West Virginia in 1875 he studied law, was admitted to the bar in 1878, and began practice at Fort Dodge, Iowa. As an orator he first attracted attention in the Blaine campaign of 1884. He was a member of Congress from 1889 to 1900, was appointed United States Senator to fill out an unexpired term, and was elected to the Senate for the terms 1901-07 and 1907-13. He was early associated with the conservative Republicans in the House of Representatives, where he was one of the framers of the Dingley Tariff Bill in 1897. During his later years in the Upper House, however, he became known as a leader among the "insurgent" Senators, and he and his associate, Senator Cummins, were perhaps the most aggressive opponents of the tariff and administration policies. One of the finest public speakers of his day, Senator Dolliver was particularly effective in his attacks (1909-10) upon the Payne-Aldrich Tariff Bill.

DOLLIVER ROMANCE, THE. A novel which Nathaniel Hawthorne engaged himself to contribute to the *Atlantic Monthly*, but which his last illness rendered him unable to complete. The first installment appeared in that magazine, July, 1864.

DOLLOND, JOHN (1706-61). A distinguished English optician, inventor of the achromatic object glass for telescopes. He was the son of a silk weaver in humble circumstances who had come to London as a French refugee. Dollond followed his father's occupation, but was also able to devote himself to the study of mathematics, optics, and astronomy. In addition he made himself acquainted with anatomy and theology, and went so far in the study of the classical languages as to translate the Greek Testament into Latin and was also able to read

French, German, and Italian. He apprenticed his eldest son, Peter (1730-1820), to an optician; and after the latter had established himself in business on his own account, he was joined by his father in 1752. John Dollond now devoted himself to the improvement of the refracting telescope, in which work he was encouraged by the most distinguished scientific men of the time. After a series of well-contrived experiments and researches, commenced in 1757 and carried on for several years, he succeeded in constructing lenses where a concave lens of flint glass was combined with a convex lens of crown glass with the result that images were produced without any colored border. (See *ACHROMATISM*.) This was undoubtedly the greatest improvement that the telescope had received since its first invention. The memoir (published in the *Philosophical Transactions* for 1758) in which he gave an account of his investigations was rewarded by the council of the Royal Society with the Copley medal. In 1761 Dollond was appointed optician to the King and was elected a fellow of the Royal Society. His two sons continued to carry on the business with great success. Consult Kelly, *Life of John Dollond* (London, 1808).

DOLL'S HOUSE, A. The English version of *Et Dukkehjem*, a play by Henrik Ibsen (q.v.), produced in Christiania in 1879 and in London in 1889. The theme is the right of individualism in woman, which is set forth in the disillusioning experience of Nora Helmer, the young wife of a man fettered by conventional idealism.

DOLLY VARDEN. In Dickens's *Barnaby Rudge*, the coquettish daughter of Gabriel Varden, a locksmith, whom she rules completely. She is impulsive, soft-hearted, and full of pretty strategies. Her dainty dress of flowered dimity, cut short enough to show her neat ankles and buckled shoes, gave the name *Dolly Varden* to a style of dress which came into fashion soon after *Barnaby Rudge* was published.

DOLLY VARDEN TROUT (from the color, which resembles a *Dolly Varden*, a gown of gay muslin print worn by women about 1865-70). The common brook trout (*Salvelinus malma*), a char of the mountains of western North America, "from the upper Sacramento to Montana, Alaska, and Kamchatka." It has a stout body, large head and mouth, and the back more elevated and less compressed than the Eastern brook trout (*Salvelinus fontinalis*); the tail is almost truncate, and the adipose fin is unusually large. "General color, olivaceous; the sides with round red spots nearly the size of the eye, the back commonly with smaller pale ones, a feature of coloration which distinguishes this species at once from the others." It abounds in the streams of the northern Rocky Mountains, where it is also known as bull trout or red-spotted trout; and in the Far Northwest, where it has the Kamchatkan name "malma"; it descends to the sea and sometimes reaches a weight of 12 pounds. It is one of the most beautiful and active of the Salmonidae and has been extensively transplanted to waters in the northeastern United States and Europe. See **TROUT**.

DOLMEN (Bret., table stone, from *dol*, table + *men*, Welsh *maen*, stone; the Welsh equivalent is *cromlech*, bending slab). The name given to a class of monuments of prehistoric civilization, consisting of several great stone slabs, set edgewise in the earth and supporting a flat

capstone for the roof, designed for a sepulchral chamber. The greatest historic interest attaches to these monuments for several reasons. They were erected in the British Isles, in northwestern France, in Spain, along northern Africa, in Syria, and chambered mounds exist as far east as Japan. They mark the Neolithic period in Europe, and their erection may be called the beginning of engineering. In Guernsey and elsewhere they are styled Druid altars and are associated with Druidical rites. By some they have been attributed to the Celts, and this raises the question whether all the dolmen builders of northern Africa and Europe and even in Japan were of the same race. If they were, they would belong rather to the Iberic branch of Sergi's Eurafic species, a strain of whose blood may have reached the Orient. Dolmens were sometimes covered with immense tumuli, and again the earth envelope reached only the capstone. Some of the mounds were of great size, as that of Silbury Hill, Wiltshire, 170 feet high, and 316 feet along the slope. In some of the chambers might have been single interments; in others, says Keane, the same mound had to do duty for many generations, the original cell expanded into the "family vault," developing a system of lateral chambers 30 × 16, and 8 feet high, with roof slabs of corresponding size, some weighing 10, 20, and even 40 tons. Consult Keane, *Ethnology* (Cambridge, 1896), and Borlase, *The Dolmens of Ireland* (London, 1897).

DOLNYA TUZLA, dōl'nyā tooz'la. The capital of a district of the same name and a garrison town in Bosnia, Austria-Hungary, picturesquely situated on the Julla, amid mountainous scenery, 38½ miles by rail southeast of Doboj. It is the seat of an Orthodox bishop. It has coal mines, alkali and salt works, a distillery, and saw mills. The salt mines have been worked since the days of the Romans. Pop., about 12,000.

DOLOMIEU, dōl'ō'myē', DEODAT GUY SILVAIN TANCÈRE GRATET DE (1750-1801). A French geologist and mineralogist. He was one of the Knights of Malta when a boy, and fought a duel with and killed a brother knight, for which he was condemned to death, but was saved in consideration of his youth. He then turned his attention to science and visited Portugal, Spain, and Sicily, making interesting observations on the geological structure of the Pyrenees. He minutely described the earthquake in Calabria in 1783 and in later years studied the Alps, where he discovered the mineral "dolomite," which is named after him. He became professor in the Paris School of Mines and a member of the Institute from its formation. In 1798 he was on the scientific staff of Bonaparte's expedition to Egypt. Here he lost his health, and on the way home was left at Messina, where he was an object of political hatred because he had revealed in 1783 to the Grand Master of Malta the designs of the Neapolitans against that island. He was confined in a wretched dungeon, clothed in rags, and given only a bed of straw. There he was kept 21 months. Denied writing materials, he made a pen from a piece of wood, and with the smoke of his lamp for ink, wrote on the margins of his Bible his *Traité de philosophie minéralogique* and *Memoire sur l'espèce minérale*. At the conclusion of the treaty between France and Naples he was released and took the chair of mineralogy at the Museum of Natural History

in Paris. His collections of mineralogy included numerous and valuable specimens. Besides the works mentioned above, he wrote: *Voyage aux îles de Lipari* (1783); *Mémoire sur le tremblement de terre de la Calabrie* (1783); *Mémoires sur les îles Ponces* (1788), etc. Lacépède's *Eloge historique de Dolomieu* is among the *Mémoires* of the Institute for 1806.

DOLOMITE (named in honor of the French geologist Dolomieu), BITTER SPAR, or MAGNESIAN LIMESTONE. A calcium-magnesium carbonate that crystallizes in the hexagonal system in forms similar to calcite (q.v.). It is white to reddish or greenish white and sometimes of darker shades, even reaching brown and black in some varieties, with a vitreous and sometimes pearly lustre. Dolomite, both as a mineral and as a rock, is found in various parts of Europe. In the United States it occurs at many localities in Vermont, Rhode Island, New Jersey, New York, and Missouri. It is found both crystallized and massive. The crystallized varieties include the *pearl spar*, which is so called from its lustre. The massive varieties are frequently colored; the variety containing iron is called *brown spar*; the varieties containing manganese and cobalt are reddish. The compact varieties are used as building stones. The Houses of Parliament in London were built from a variety found at Bolsover Moor, and St. Patrick's Cathedral, in New York City, is built from a variety found in Westchester Co., N. Y. Calcined and slaked, dolomite yields a cement offering considerable resistance to the action of water. Calcined dolomite is used as a lining for Bessemer converters (see IRON AND STEEL), and the mineral when treated with sulphuric acid yields calcium and magnesium sulphates and so is used in the manufacture of Epsom salts.

DOLOMITES (from the mineral, dolomite, which, in turn, was named from Dolomieu, the geologist). The limestone Alps of South Tirol, between the Adige and Piave rivers. The highest summit, Marmolata, rises to 11,000 feet. Strictly speaking, the term "Dolomite" belongs to the Fassa Mountains, the Langkofel, Rosen-garten, and Schlern, but does not apply to the Cristallo, Hohe Gaisl, Tofana, Sorapsis, Antelao, Pelmo, and other peaks of the Ampezzo Limestone Alps; but as these mountains are widely known as the "Ampezzo Dolomites," the popular nomenclature is generally adhered to.

DOLOO'. The capital of Mandara (q.v.).

DOLORES, dô-lô-râs. A town of the Argentine Republic, in a district of the same name, Province of Buenos Aires, 127 miles by rail from Buenos Aires (Map: Argentina, H 5). It has manufactures of culinary implements. Pop., 1903, 10,000; 1911 (of district), 25,751.

DOLPH, dôlf, JOHN H. (1835-1903). An American genre and animal painter, born at Fort Ann, N. Y. He studied in Antwerp under Van Kùyck and in Paris and afterward opened a studio in New York City. He began as a genre painter with such subjects as "The Knickerbocker Farm Yard" (1869), "Beggars" (1874, James Gordon Bennett, Paris), "The Antiquarian" (1876); but later made a specialty of pictures of kittens and puppies, which gained him great popularity. Although always carefully executed in a graceful and spirited manner, their endless repetition prevented the higher development of which his art was capable. He was a member of the National Academy of De-

sign and one of the founders of the Society of American Artists.

DOLPH, JOSEPH NORTON (1835-97). An American politician. He was born at Dolphsburg, N. Y., and was educated at Genesee Wesleyan Seminary at Lima, taught school, studied law at Havana, N. Y., and was admitted to the bar in 1861. In 1862 he emigrated to Oregon, crossing the plains as a member of Captain Crawford's "Oregon Escort," a volunteer company authorized by act of Congress to protect emigrants to the Pacific coast. In 1863 he began the practice of law at Portland, Oreg., in partnership with John H. Mitchell, afterward United States Senator. In 1864 he was elected city attorney, and in 1865 was appointed by President Lincoln United States Attorney for the District of Oregon. He served in the Oregon State Senate (1866-68 and 1872-76) and was United States Senator from Oregon from 1883 to 1895.

DOLPHIN (OF. *dolphin*, *daulphin*, Lat. *delphinus*, from Gk. *δελφίς*, *delphis*, dolphin). A cetacean of the family Delphinidæ, characterized by the moderate relative size of the head, differing in this from the cachalots, and also usually by having numerous simply conical or nearly conical teeth in both jaws, although some of the species lose those of the upper jaw at an early age. The blowhole is single. The family Delphinidæ includes, along with the dolphins, blackfish, porpoises, grampuses, etc., many animals which on account of their larger size are commonly called whales, as the beluga, etc. The names "dolphin" and "porpoise" are often used interchangeably, but the true dolphins have the snout prolonged into a rather slender beak, which is abruptly separated from the convex forehead, even by a marked furrow; both jaws are furnished with numerous equal teeth. The species are numerous, and none apparently has a very wide geographical range. They are voracious animals, and are said to prey not only on fishes, medusæ, cephalopods, etc., but even on the wounded and feeble of their own species. They live in herds, which often delight the voyager in the ocean solitude by their gambols. (See also about a ship, they display their agility in a thousand graceful motions, now leaping with curved bodies many feet into the air, then darting through a wave with incredible velocity, leaving a slender wake of whitening foam under the water; now the thin back fin only is exposed, cutting the surface like a knife; then the broad and muscular tail is elevated as the animal plunges perpendicularly into the depths.

The common dolphin (*Delphinus delphis*) is found in the Mediterranean and in the northern Atlantic Ocean. It is usually not more than 6 or 8 feet long, but individuals have been seen of 10 feet. The body tapers towards the tail, which is crescent-shaped and about a foot in breadth. The beak is about 6 inches long, and the blowhole crescent-shaped. The color is blackish on the back, grayish on the sides, and satiny white below. The female dolphin brings forth a single young one at a time, which she suckles and nurses with great care. The flesh of the dolphin was formerly considered a delicacy, and sailors still regard the capture of one as a happy event, giving a beeflike alternative to their fare of salted meat.

From the form of its beak the dolphin receives from the French the names of *bec d'oie*

(goose-beak) and *oie de mer* (sea goose). It was very differently regarded and designated by the ancient Greeks, to whom it was *hieros ichthys* (sacred fish), and was invested with many fabulous attributes and was the subject of many mythological legends. It was supposed to be peculiarly friendly to men, perhaps because the dolphin emits a peculiar murmuring or suppressed lowing cry. It was sacred to Apollo, who was worshiped at Delphi with dolphins for his symbols. The figure of the dolphin, therefore, appears on many ancient coins and medals. It is said to have been borne on the shield of Ulysses; early appeared on the shield of some of the princes of France and gave its name to one of the fairest of the French provinces, whence the heir apparent of the French throne came to be styled "dauphin." It is not easy to account for the high regard in which the dolphin was anciently held; nor is it altogether easy to explain the very general transference of its name in modern times to the coryphene (q.v.), a true fish, renowned for those changes of color in its dying moments which poets have delighted to celebrate. Similar attributes are popularly given in Brazil to a dolphin (*Sotalia guianensis*), very abundant in the Bay of Rio de Janeiro, which the natives assert will bring to shore the bodies of drowned persons. This genus (*Sotalia*) has Oriental and African species ascending rivers, one (of the Kamerun River) having the nostrils (blow-holes) prolonged into a snoutlike process.

The European dolphin is rare on the coast of the United States, but three or four other species occur, one of them, at least, numerous. This is the bottle-nosed dolphin (*Tursiops tursio*), which is caught in considerable numbers on the New Jersey coast and also near Cape Hatteras. At the latter place these animals are captured in large seines, sometimes as many as 1000 in one year. Twelve feet is about the maximum size. They produce valuable oil and leather. The oil from the head is of especial fineness and is worth about \$20 a gallon refined. It is used for watches. Closely allied to this species is the "black" dolphin (*Tursiops erebennus*), which is not quite so large and is wholly black in color. The spotted dolphin (*Prodelphinus plagiodon*) is occasionally found on our coasts. It is dark slate-color above, and pale or white below, somewhat spotted with slate. See BLACKFISH. Consult True, *Review of the Family Delphinidae* (Washington, 1899).

DOLPHIN. A fish. See CORYPHENE.

DOMAIN. See DEMESNE.

DOMAS Y VALLE, dō'mās ē vā'lyā, José (c.1717-1803). A Spanish naval commander and colonial governor, born at Cartagena. He advanced rapidly and within six years of his admission to the navy attained the rank of chief of squadron. He participated in many engagements in the Mediterranean and was commander of the vessel *Asís* in the West Indies during the war with England (1779-80). During this campaign occurred his brilliant action in capturing treasure ships of the crown, with which 5,500,000 pesos he had received for the King, from Vera Cruz to Havana, past the fleet of Admiral Rodney, who knew all about his course, his squadron, and its cargo. After participating in the capture of Pensacola (1781) and later in the siege of Gibraltar, he served as Governor of Panama from 1786 to 1794 and

then became Captain General of Guatemala, and President of its Real Audiencia.

DOMASZEWSKI, dō'mā-shēf'skē, ALFRED VON (1856-). A German historian. He was born in Temesvár, Hungary, and was educated at the University of Vienna, where he was assistant in the Numismatic Collection (1884-87) and privatdocent. In 1887 he went to Heidelberg as professor of ancient history. He did important work on the corpus of Latin inscriptions, edited, with Dessau, a revision of Marquardt's *Römische Staatsverwaltung*, and wrote on the Roman army, Roman religion, and the history of the Empire: *Fahnen im römischen Heer* (1885), *Religion des römischen Heeres* (1895), *Die Rangordnung des römischen Heeres* (1908), *Abhandlung zur römischen Religion* (1909), *Geschichte der römischen Kaiser* (1909), and, with Brünnow, *Die Provinz Arabia* (1904-09).

DOMAT, dō'mā', or **DAUMAT**, JEAN (1625-96). A French jurist. He was associated with the recluses of Port-Royal and with Pascal, who bequeathed to him his private papers. His elaborate digest, entitled *Lois civiles dans leur ordre naturel* (3 vols., 1689-94), places him among the first jurists of his century, though it was not until after 1726, when Blackstone commended the work and it was translated into English, that it received any degree of attention outside of France. He also published *Le droit public* (1697) and *Legum Delectus* (1700).

DOMATIA, dō-mā'shi-ā (Neo-Lat. nom. pl., from Gk. δωματιον, *dōmatíon*, little house, dim. of δῶμα, *dōma*, house). Portions of plants which are modified so as to form chambers in which various organisms, especially fungi or small animals, may dwell. See SYMBIOSIS.

DOMBASLE, dōn'bāl', CHRISTOPHER JOSEPH ALEXANDRE MATHIEU DE (1777-1843). A French agriculturist, born at Nancy. In 1822 he was appointed director of the agricultural institute at Roville. He invented the plow which bears his name. An important innovation introduced by him was the use of lime in clayey soils. He contributed greatly to the improvement of agriculture in France by his works upon that subject, such as *Essai sur l'analyse des eaux naturelles* (1810); *Calendrier du bon cultivateur* (1821); *Théorie de la charrue* (1821); *Instruction sur la distillation des grains et des pommes de terre* (1829).

DOMBES, dōnb. A district of eastern France entirely included within the department of Ain. It is surrounded on three sides by the rivers Saône, Rhône, and Ain, and on the north by the district of Breese. A peculiarity of the district is the clay soil which does not absorb the rainfall, permitting large pools to form. These cover many acres at certain seasons of the year and render the climate very unhealthy. In the past, the entire district has been swept by disease many times, but large drainage works have since been constructed, and certain laws of sanitation laid down. Large numbers of the pools remain, however, and are used for the cultivation of fish. Dombes, Latin *Dumbæ*, was once part of the Kingdom of Arles. In 1402 Louis II formed the Principality of Dombes, and in 1762 it came under the French crown. Area, 440 square miles.

DOM'BEEY AND SON. A novel by Charles Dickens, first published serially in 1846.

DOM BOC. dōm'bók (AS. book of dreams or

sentences, Lat. *liber judicialis*), or DOOMBOOK. The code of laws compiled by King Alfred chiefly from the West Saxon collection of his own ancestor Ina, but comprising also small portions of the Mercian laws of Offa and of the Kentish collection of Ethelbert, with the supplements of his successors. "Ina's collection," says Dr. Pauli, "was the only one received entire into the Codex, which was chiefly applicable to the condition of the West Saxons. A few articles were admitted here and there from the Kentish and Mercian laws, but research into this matter is not possible, as Offa's book is lost." Alfred made few, if any, original laws, but contented himself with restoring, renovating, and improving those which he found already in existence. The peculiarly Christian character of the King is strongly impressed on this code, which begins with an extract from the Bible: "The Lord spake these words to Moses, and thus said: I am the Lord thy God." Then follow most of the Ten Commandments, some parts of the Mosaic law relating to criminal offenses, and passages from the New Testament, including the Golden Rule. The code was ratified by the Witan, as Alfred expressly informs us. Consult Pauli, *Alfred the Great*, from the German (London, 1857), and Thorpe, *Ancient Laws and Institutes of England* (ib., 1840).

DOMBROWSKI, döm-brów'skê, or **DABROWSKI**, JAN HENRYK (1755-1818). A distinguished Polish general, born in Pierszowice, in the District of Cracow. He entered the service of the Elector of Saxony in 1770, but in 1792, on the first symptoms of the insurrection in Poland, proceeded to Warsaw. He took part in the Polish campaigns against Russia and Prussia and exhibited remarkable military talents. In 1796 Dombrowski went to France, where he was commissioned by the Directory to form a Polish legion among his exiled countrymen. The legion signally distinguished itself in the Italian campaign. In the campaign of 1799-1800 Dombrowski gave proofs of remarkable courage. After the Peace of Amiens he became a general of division in the service of the Cisalpine Republic, and after the battle of Jena he was ordered by Napoleon (1806) to summon his countrymen to arms. His entrance into Warsaw at the head of the Polish divisions resembled a classical triumph. At Dirschau and Friedland he won fresh laurels. In the fatal Russian campaign of 1812 he commanded one of the three divisions of the Fifth Army Corps and at the passage of the Beresina saved from destruction the relics of Poniatowski's corps. In 1813, at the head of his Poles, he took an honorable part in the battles of Teltow, Grossbeeren, Jüterbogk, and Leipzig. After the fall of Napoleon Dombrowski returned to Poland, and in 1815 was appointed by Alexander I a general of cavalry and a Polish senator, but in the following year he withdrew from public employment to his estate at Posen. He died June 6, 1818. Consult Zhodzko, *Histoire des légions polonaises établies sous le commandement du général Dombrowski* (Paris, 1829).

DOMBROWSKI, JAROSLAW (1835-71). A Polish Socialist, agitator and revolutionist. He was born at Zlatomir, Volhynia, and entered the academy of the general staff at St. Petersburg in 1848. In 1860 he left the government service and participated in Garibaldi's advance

on Naples. In 1864, owing to his complicity in the insurrection at Warsaw, he was condemned by the Russian government to 15 years' imprisonment at hard labor and was transported to Siberia. Before arriving at his destination, however, he escaped and fled to Paris (1865). On the outbreak of the War of the Commune, March 18, 1871, he was appointed commander in chief of the Communist forces stationed at Asnières by the central committee of the National Guard. In the following month he succeeded to the chief command of the entire revolutionary forces; but, after fighting at Neuilly and Montmartre, he was killed by the government troops while defending the barricade at the Boulevard Ornano.

DOMDAN'TEL. An immense submarine cavern near Tunis; a seminary for the black arts, introduced in the continuation of the *Arabian Tales*. Southey narrates its final destruction in *Thalaba*.

DOME (OF. *dome*, Fr. *dôme*, from Lat. *domus*, Gk. *δῶμος*, OChurch Slav. *domŭ*, Skt. *dama*, house; connected ultimately with OHG. *zimbar*, Ger. *Zimmer*, Icel. *timbr*, AS., Eng. *timber*; the word is also influenced by Lat. *doma*, Gk. *δῶμα*, house). A term in architecture bearing a twofold meaning. It is loosely used, after the fashion of the German *Dom* and Italian *duomo*, to designate a cathedral or some other building of importance, but its only genuine English scientific meaning is that of a convexly curved vault or roof having a circular or polygonal (or rarely elliptical) plan. It may be of any material—wood, stone, metal, earthenware, etc. It may be built of a single thickness or with two or even three shells; it may spring directly from the substructure, or be raised upon a high drum; it may be of low curvature, like that of the Pantheon at Rome, or of steep or ovoid or bulbous outline, like many Persian and Indian domes, and be crowned with a lantern or be without one. The supporting substructure may be a closed circular building or it may be an open structure of four or more arches bearing pendentives (q.v.). The term is often interchangeable with *cupola* (q.v.). By some writers the distinction between *cupola* and *dome* is made by referring the first only to the inner surface or shell of a domical roof or vault, and confining the use of *dome* to the outer roof or shell. A clearer distinction is that which applies the name "cupola" to domes which rest directly on the building without the interposition of a drum, using "dome" in the more general sense of the definition given above, which includes cupolas.

The history of the dome falls into two great divisions—the period before and after the invention of the dome on pendentives; or, roughly speaking, the period before and after the building of Hagia Sophia in Constantinople. It was known to the Assyrians and Persians, who used it over houses and palaces, sometimes with low, semicircular outline, sometimes with high ovoidal or pointed outline. These domes were made usually of brick and rested on solid walls. The Pelasgic and Mycenaean tribes also used the dome, but they built it of stone, starting its curvature from the ground, and constructing it not like a true vault, in which the courses have beds normal to the curve of the dome, but with horizontal beds, the courses successively projecting inwards each over the one below till they met at the top. Such was the Tholos of

Atræus at Mycenæ. The early Italian tribes, as well as those of Greece, used this kind of dome, which appears in Etruria and Latium (e.g., Vetulonia), where there even appear signs of the Oriental form. The Romans, however, appear to have been the first to give really monumental expression to the dome. With them it was a hemispherical vault of brick or of brick and concrete, resting solidly upon its circular base, as in the Pantheon, built by Hadrian, which remains the largest masonry dome in the world, 142 feet in diameter. A remarkable feature of this dome is the oculus, or opening, at its summit, the only window of the building; the effect of this method of lighting is singularly impressive. Smaller domes are those of the temple of Minerva Medica, in Rome, some of the halls in the *thermæ*, and a number of tombs of presumably late date. This form was popular in the Christian period for mausoleums, as in Santa Costanza, Rome, in which for the first time a dome was carried not by a con-

four piers and arches were made to suffice. The vast scale of Hagia Sophia, whose dome is 107 feet in diameter and rises to a height of 180 feet was never afterward duplicated, other Byzantine domes being much smaller and usually arranged in groups. The lateral thrust of these domes was resisted by buttresses or by the vaults of galleries and aisles. In Hagia Sophia (see SAINT SOPHIA) another great innovation was introduced in the form of a crown of 40 windows penetrating the base of the dome, which was strengthened by buttresses between them. This method of lighting is also seen in St. Mark's at Venice, built 500 years later, and was copied by the Turkish conquerors after 1453 in their mosques. In the later Byzantine churches, with their smaller domes, as such windows would have been trivial and inadequate, the dome was raised on a cylindrical drum (q.v.) in which were windows of practicable size. The ribbed system of construction of the vaults of St. Sergius and of Hagia Sophia

Note the increased depth of the dome as seen from inside, so that its main thrust is downward.

tinuous wall, but by a series of isolated supports, in this instance by 12 arches borne on a double circle of columns (c.325 A.D.). The dome was also a common form of roof for baptisteries (e.g., Ravenna, Nocera, Pisa, Florence). In the sixth century, after tentative attempts at Ezra in Syria, at San Vitale, Ravenna, San Lorenzo, Milan, and St. Sergius and Bacchus in Constantinople, the problem of suspending the dome on pendentives instead of on solid walls was solved in the church of Hagia Sophia, Constantinople. This was an invention, therefore, of Byzantine architecture and ushered in the second and more important period of dome construction. *Pendentives* (q.v.) are convex triangular spaces comprised between the arches springing from piers at the angles of a square or octagon and the circular base of the dome. By their means the dome is carried upon four or eight widely spaced isolated supports, between and beyond which the plan of the building may be extended in any direction and made to take on any outline or form desired. In the four transitional examples named above, eight supports were employed; in Hagia Sophia, for the first time,

was generally abandoned, and the vaults built in circular courses or rings, which were simpler and easier to construct.

In the Middle Ages the dome was generally abandoned in the West, though in Italy it was still used over the crossing in many Lombard and Romanesque churches and wherever the Byzantine influence was strong. The largest of these crossing domes is that of Pisa, which is elliptical and probably of plaster. Baptisteries were generally vaulted in Italy, and the eleventh-century dome of the Florentine baptistery was the largest octagonal vault in existence until the dome of the cathedral was built after 1420. That at Nocera, reproducing the general plan of Santa Costanza, is about 42 feet in diameter, or about half the diameter of the Florentine example. The octagonal and decagonal vaults of English-Gothic chapter-houses are ribbed vaults, not domes. The Old Cathedral at Salamanca, Spain, has a *cimborio*, or crossing dome, raised on a high drum; it is a ribbed dome internally, though covered externally by a low polygonal spire. There are also in Aquitania and about Périgueux in France a number of twelfth-century churches

with domes on pendentives, evidently derived from Byzantine prototypes, through the intermediary of Venice and Cyprus (Souillac, Solignac, Saint-Front at Périgueux, Angoulême, etc.). Meanwhile the dome was being developed by the Moslems into a feature now inseparably associated with the Orient. The dome of the Rock (Mosque of Omar) at Jerusalem, the largest of Arab domes and perhaps the earliest, is of wood, probably recalling that of the Byzantine church it replaced. Other Arab domes are small; the feature was first introduced in the tenth century in mausoleums connected with mosques in Cairo and elsewhere, but after the fourteenth century it was used over the prayer halls themselves, as in Kaït Bey at Cairo (1465). The Arab domes are ovoid or pointed in outline, often ribbed or carved on the outside, and carried on complex decorative corbelings of stalactite work (q.v.) instead of pendentives. In Persia a new type was invented: the swelling or bulbous dome. These domes were of brick, on pendentives of ingeniously interlaced ribs and vaults; many are of great beauty. This type spread to India, where it was reproduced in stone and marble, often on an imposing scale; that of the tomb of Mahmūd at Bijapur is 124 feet in diameter over a rotunda of 137 feet. Other important Indo-Moslem domes are those of the Ettimēddoullah and Humayūn mausoleums, which surpass in size, though they do not approach in exquisite beauty, the alabaster dome of the Taj Mahal at Agra (1660). The Turks, after the conquest of Constantinople in 1453, employed Greek architects to build their earlier mosques after the pattern of Hagia Sophia, modified; and the noble domes of the Imperial mosques, especially of the Ahmediyē and Suleimaniyē, are the fine though tardy fruitage of the grand early Byzantine conception of Hagia Sophia. They present the sharpest contrast to the fantastic bulbous lanterns and towers of the Russian churches of Moscow, Nijni Novgorod, etc., which show the late Byzantine drum elongated into a high narrow turret, and the dome replaced by a bulbous termination of singularly Oriental aspect.

The Renaissance architects of Italy developed the dome as the distinctive feature of their church architecture, making of it a superb external feature by raising it upon a high drum and crowning it with a lantern. The earliest example is also the largest; it is that of the Duomo at Florence, built from Brunelleschi's designs, partly under his direction, between 1420 and 1446, and after his death in that year completed from his models in 1464. This is an octagonal dome, wholly of masonry in two shells carried by eight colossal ribs meeting in a ring at the summit, and 16 intermediate lesser ribs. The dome is 139 feet in diameter and 380 feet high to the top of the lantern. Domes on pendentives cover the crossings of nearly all the Italian Renaissance churches, and after the fifteenth century a number of large churches were built having a square or polygonal central area covered by a dome, sometimes with four half-domed apses opening out of it (Umiltà at Pistoia, Incoronata at Lodi, Consolazione at Todi, etc.). In 1506 Bramante began the building of a mausoleum church for Julius II on the site of the ruined basilica of St. Peter at Rome, with a central dome 137 feet in diameter on four arches with pendentives. Out of

this design, under the hands of later architects, grew the colossal church of St. Peter (q.v.), to which definite form was given by Michelangelo, whose final design for the dome, unfinished at his death in 1565, was carried out with slight changes by Della Porta and Fontana. This, though not the largest in diameter, is incomparably the finest and noblest of all domes, superb especially in its external form and proportions. It is 405 feet in total height, built in two shells resting on a magnificent drum adorned with 16 coupled column buttresses. This dome fixed the type for Italy and western Europe. In Italy hundreds of domed churches were erected between 1560 and 1800; and the domes of the Baroque period are the finest features of these churches, even when these are otherwise of commonplace or inferior design. In France the Sorbonne (Paris, 1635) was the earliest church with an important exterior dome; the Val-de-Grace, completed somewhat later, is of unusually elegant proportions; but both were far surpassed by the dome of the Invalides, by J. H. Mansart, begun in 1675. In this there are three shells—an inner one of stone with a large oculus, or opening, through which, as a frame, one sees the painting on the inner surface of the second shell, also of stone. The outer shell and lantern are of wood covered with lead. The Panthéon (1755–81 by Soufflot) also has three shells, but all are of stone as well as the lantern, which is carried by the second shell. In this arrangement, as well as in the peristyle about the drum, Soufflot followed the model set by Sir Christopher Wren in the noble dome of St. Paul's in London (1675–1710). Here the intermediate shell is conical below, like the dome of the Pisan baptistery, and carries the stone lantern, while the outer shell is of wood. Among later European domes may be cited the fine Panthéon-like rotunda of the church of San Francesco da Paola at Naples (1812), the dome of San Carlo at Milan, 108 feet in diameter, that of the church at Mistra in Malta, and the cast-iron dome of the cathedral of St. Isaacs, St. Petersburg. In the United States the dome of the capitol at Washington (by Walter, 1856–73), though unfortunately of cast iron, is externally of unusual beauty and dignity of design; its inner shell covers a rotunda 90 feet in diameter. (See illustration under WASHINGTON.) As far back as 1795 the dome had been adopted by Bulfinch as an external feature of the State capitol at Boston, and it has ever since been a distinguishing element of American State capitols: those of Minnesota at St. Paul, and of Wisconsin at Madison, are important recent examples. The dome of the Columbia University Library (New York) is 80 feet in diameter, of two shells—the inner one of steel and plaster, the outer one of masonry. The use of steel and concrete has made possible domes of great size at low cost, and the Guastavino system of vaulting has produced domes of great lightness as well as beauty in both religious and secular buildings. But the vast rotunda roof of the Vienna Exhibition of 1873, still standing, is not a dome, but a conical trussed roof of iron and glass over a rotunda 360 feet in diameter. The largest concrete dome thus far constructed (1914) is that of the new Public Library at Melbourne, Australia; it is 124 feet in interior diameter.

DOMENICHINO, dô-mă'né-kě'nô, properly DOMENICO ZAMPIERI (1581-1641). An Italian painter of the eclectic school (q.v.). He was born in Bologna, Oct. 21, 1581, and studied for a time under Denys Calvaert, but chiefly under the Carracci. Among his schoolmates were Guido Reni and Francesco Albani; with the latter he formed a lifelong friendship. Together they visited Parma, Modena, and Reggio, studying the works of Correggio and his school, and it was in response to Albani's urgent letters that Domenichino went to Rome in 1603.

In Rome he was well received by his countrymen, especially by his teacher, Annibale Carracci, whom he assisted in his frescoes in the Palazzo Farnese. On Annibale's recommendation, he and Guido were employed in decorating the chapel of Sant' Andrea in the church of San Gregorio. In executing this commission a rivalry arose between the two painters. Both represented the "Martyrdom of St. Andrew," but while Guido chose the moment where the saint, at sight of the cross, falls into an ecstasy, Domenichino painted the martyrdom itself, in all its gruesome details. In 1614 he painted, for the church of San Girolamo della Carità, his "Last Communion of St. Jerome," now occupying a place of honor in the Vatican collection opposite Raphael's "Transfiguration." It is a noble and well-balanced composition, full of action, and is unquestionably the best of his works. In connection with his stay in Rome Domenichino decorated the villa of Cardinal Aldobrandini, in Frascati, with frescoes representing mythological scenes in heroic landscape, and the abbey of Grotta Ferrata with a fine series representing the life of St. Nilus (1609), among which the "Meeting of the Saint with the Emperor Otho" is particularly good. He also decorated the church of San Luigi dei Francesi in Rome with frescoes from the life of St. Cecilia.

In 1617, wearied by the annoyances caused by the jealousy of the painters in Rome, he returned to Bologna, and in 1619 he was married. From this time the Raphaelesque type of women disappears from his pictures and is replaced by one less impressive, indeed, but full of charm and more realistic—the image of his wife. His chief work of this period is the "Madonna of the Rosary," now in the Gallery of Bologna. In 1621 he returned to Rome and was named principal architect of the Papal Palace.

The chief works of his second stay in Rome were the "Four Evangelists," on the pendentives of the cupola of Sant' Andrea della Valle—noble and impressive representations—and a charming mythological canvas, "Diana and her Nymphs Hunting," in the Palazzo Borghese, Rome. In 1631 he went to Naples to decorate the Capella del Tesoro, in the cathedral, with frescoes representing the life of St. Januarius; but he was so restricted by his instructions and annoyed by the murderous threats of Neapolitan artists that he was unable to produce his

best work. He died suddenly at Naples, April 6, 1641, supposedly by poison. He was a man of modest disposition, diligent and conscientious in his work, and capable of fine and high emotions.

Domenichino and Guido Reni were the most important of the pupils of the Carracci, and Domenichino, though somewhat lacking in originality, was the most naturalistic of them all. His art is midway between that of the Carracci and Caravaggio. His works are uneven in color, and the dominating tone is a soft gray. He was fond of using landscapes as backgrounds which were of high decorative value, and also painted independent landscapes (Capitoline Gallery, Rome, and Pitti Palace, Florence). His portraits belong to the best done by the Bolognese school, good examples being the portrait of Vincenzo Scamozzi in the Berlin Museum, and that of Cardinal Agucchi, in the Uffizi Gallery, in Florence. As an architect he did some creditable work, but as a sculptor he was less successful. Consult the authorities referred to under **BOLOGNESE SCHOOL OF PAINTING**, and the monographs on Domenichino by Roncagli (Bologna, 1842); Breton (Saint-Germain, 1867); Serra (Rome, 1909).

DOMESDAY BOOK, or DOOMSDAY BOOK.

A statistical account of the state of England in the latter part of the eleventh century, prepared by command of William the Conqueror in the year or years just preceding 1086. It is one of the oldest and most valuable of English historical records. The origin and significance of the name is a matter of dispute. The Anglo-Saxon *Domas* were laws or dooms, and the term *Dom boc* occurs in the laws of King Æthelstan and in the ecclesiastical laws of King Edgar. In a specific sense the Anglo-Saxon Gospels use the word *domesdæg* for "judgment day." The inference, therefore, is that, as applied to the famous record which became the basis for the adjustment of all future land relations, the term contains the two ideas of supreme authority and of final judgment or doom. The book has been known by several other names. It is mentioned as the *Rotulus Wintonia*, or the 'Winchester Roll'; *Scriptura Thesauri Regis*, or 'The Writings of the King's Treasury'; *Liber de Wintonia*, or the 'Book of Winchester'; and *Liber Regis*, or 'The King's Book.' The book itself bears in its colophon or seal the simple title *Descriptio*.

An anonymous contemporary has told the story of the *Domesday Book* in simple and vigorous language, and a translation of this plain and faithful narrative will best describe the way in which the work was first set on foot: "In the year 1085, . . . at midwinter, the King [William the Conqueror] was at Gloucester with his Great Council, and there held his court five days; and afterward the archbishop and clergy had a synod of three days. There were Maurice chosen Bishop for London, and William for Norfolk, and Robert for Cheshire. They were all the King's clerks. After this the King had a great consultation and very deep speech with his council about this land—how it was peopled, or by what men. He then sent his men all over England, into every shire, and caused them to ascertain how many hundred hides of land it contained, and what lands the King had in it, what castles there were in the several counties, and how much revenue he ought

to get yearly from each. He also caused them to write down how much land belonged to his archbishops, his bishops, his abbots, and his earls, and—that I may be brief—what property every inhabitant of England possessed in land or in cattle, and how much money this was worth. So very straitly did he cause the survey to be made that there was not a single hide nor a yardland of ground, nor—it is shameful to say what he thought no shame to do—was there an ox or a cow or a pig passed by that was not set down in the accounts, and then all these writings were brought to him.” The survey was made by the King’s commissioners, but they seem to have had the aid of the chief men of every shire. A sworn jury, composed of the sheriff, lords of manors, priests, heads of hundreds, bailiffs, and six village tenants, made the inquest. There has been preserved for us the “Inquest of the County of Cambridge,” an example of the return of the survey of that county. The *Domesday Book* for Cambridgeshire was afterward compiled by the royal secretaries. In making this transcription many errors and omissions were made. The same fact is noted when the *Domesday Book* is compared with the Exeter *Domesday*, an original return for the five southwestern counties of Devon, Cornwall, Dorset, Somerset, and Devon. The enumeration of the cattle and swine, which the chronicler thought so shameful, is recorded in the original return for these counties, but is omitted from the *Domesday Book*. The omission was doubtless intentional, because such data could have no permanent importance. The errors and omissions, however, indicate beyond doubt that the persons who collected the original information were not the compilers and writers of the *Domesday Book*.

The local jury made the inquest as to the name of the place, who held it in King Edward’s time (1042–66), and who was the actual possessor. They ascertained the number of hides in the manor, and what portion was reserved in the lord’s own hand. The villeins, cotters, and serfs, freemen, and socmen were enumerated. A census was made of the wood, meadow, and pasture, together with the number of mills and fishponds. Of all this there was to be a threefold return or valuation—as the land was held in King Edward’s days, as it had been given by King William, and as it stood at the time the survey was made—and the jurors were to say further whether the assessment could now be raised. On the basis of the divisions of the country given in *Domesday* the taxes were levied.

The value of *Domesday* as an historical document can best be understood from an enumeration of the subjects which it elucidates. Besides giving the names of all those who held land under King Edward, and of the fortunate Normans who supplanted them after the Conquest, the book treats of the ancient customs of the realm in great detail. It describes the duties of the cities and towns when the King visited them, sets forth all the titular distinctions of the period, ecclesiastic, official, and lay, and mentions the different trades and occupations of the time. There is a classified census of the people, together with an account of the condition of the country, town, and city population. The measures of land are amply recorded, as are also the territorial names, jurisdictions, franchises, tenures, and services. Lists of foreign tenants and lands held by foreign monasteries have been compiled from the names

enumerated in the book. Castles, manors, and markets find mention, as well as the condition of the churches, with their endowments and tithes. The book contains information about the metals in use at the time, and also about the quarries of stone and the springs from which salt was obtained. Eight varieties of money are spoken of, and innumerable facts are given about their use. We get occasional hints as to the legal procedure of the time, both civil and criminal. The mere statement which has been made of its contents is enough to show the immense value of the *Domesday Book* for all purposes of inquiry into the condition of England under the early Norman kings. “It will ever,” says Dr. Stubbs (*History of England under the Normans and Angevins*, London, 1845), “be found an inexhaustible source of information respecting the Anglo-Saxon and Norman constitutions, particularly in regard to the rights and revenues of the kings and their vassals, the relations of cities and towns, statistical accounts of various kinds, families and landowners, together with innumerable matters highly interesting to inquiring posterity, though unnoticed by the chroniclers of those times, either as too well known or as worthless. An intimate acquaintance with *Domesday* should supply the basis of every historical account of the Anglo-Saxon and Norman Ages.”

The *Domesday Book* first appeared in print in 1783, in two folios. Types were cast for the purpose, so as to represent the abbreviations and contractions of the original manuscript. The work was 10 years in passing through the press. In 1816 two supplementary volumes were published. One contained an excellent general introduction by Sir Henry Ellis of the British Museum, with indexes of the names of places and of tenants in chief mentioned in the work. The other volume contained four other records of the same nature: (1) the *Exeter Domesday*, already mentioned; (2) the *Inquisitio Eliensis*, a record closely resembling the Exeter *Domesday*, containing the survey of the lands of the monastery of Ely, in the counties of Cambridgeshire, Hertford, Essex, Norfolk, Suffolk, and Huntingdon; (3) the *Winton Domesday*, containing two surveys of the city of Winchester—one made between 1107 and 1128, and the other in 1148; and (4) the *Boldon Book*, a survey of the possessions of the see of Durham, made in 1183. This work is especially valuable in that it partially makes up a deficiency in the survey for *Domesday Book*, which did not extend to the counties of Durham, Northumberland, Westmoreland, and Cumberland, either, it would seem, because they had lately been laid waste by the Conqueror, or because his authority was not fully established in them. A new and better edition of the *Boldon Book* was issued in 1852 by the Surtees Society, which in 1857 printed *Bishop Hatfield’s Survey*, another record of the possessions of the see of Durham, compiled between 1345 and 1381. In 1861 a facsimile copy of that part of *Domesday Book* which related to Cornwall was published by the Ordnance Survey as an example of what could be done by the process of engraving called photozincography. This experiment proving successful, the government continued publishing the rest of the *Domesday Book*, county by county, in the same way.

In 1872 the government ordered a general re-

turn of owners of land to be prepared by the Local Government Board. This new *Domesday Book* was published in 1874-76.

Bibliography. The literature of the subject is extensive. The various volumes in *The Victoria County History* give a translation of the text for each county, with commentary and map. The more valuable secondary books are: Maitland, *Domesday and Beyond* (London, 1897); Freeman, *History of the Norman Conquest*, vols. iv, v (Oxford, 1869-76); Ellis, *General Introduction to Domesday Book* (2 vols., London, 1833); Léchaudé D'Anisy, *Recherches sur le Domesday* (Caen, 1842); *Domesday Studies*, ed. by Dove (2 vols., London and New York, 1888, 1891); Round, *Feudal England* (London, 1895); Birch, *Domesday Book: A Popular Account* (ib., 1887, containing a good bibliography of the subject); Ballard, *The Domesday Boroughs* (Oxford, 1904); *The Domesday Inquest* (London, 1906).

DOMESTIC (Lat. *domesticus*, from *domus*, house) **ANIMALS.** Those species of animals which have been brought under control by man and adapted to his uses or pleasure.

Significance and Effects of Domestication. Domestication implies taming and accustoming to the presence of man, to a greater or less extent, and a change from the wild habit; but the mere taming of an individual does not constitute domestication. Cultivation through a series of generations is necessary to fix domestic traits; and this is usually accompanied by a system of selection and breeding to develop and render permanent the qualities which are especially desirable. Domestication also implies a certain amount of care of the species, protection from severe weather, from wild animals, and from one another, and the providing of food or of the conditions under which it may be obtained. Domestic animals are also trained to some extent and are confined or kept within bounds, and, in general, their activities and lives are under control, as distinguished from the freedom and the self-dependence of the wild state.

The changes in food, environment, habits, function, and breeding bring about many modifications in the outward form, external appearance, temper, and general character of animals, which soon distinguish them from their progenitors. The hair or wool becomes of a softer texture, the color of the coat or feathers changes, and the general conformation of the animal is greatly altered. The changed habits of life, as well as the food, and the daily work or exercise, tend to the development of some parts of the body more than others, the emphasis of some characteristics and the suppression or elimination of others. Thus, the skull of hogs which have not been required to root for their food has become shorter and the snout much blunted, and the intestines of the improved breeds of hogs are much longer in proportion to the size of the animal than those of the wild or earlier domesticated forms. This undoubtedly means that the modern pig, which is highly fed to hasten its growth, can eat a larger quantity of food in a given time, and it may indicate that he can digest it more thoroughly than his ancestors.

It may be said, in general, that under domestication animals mature earlier, become more fertile, often more prolific, and present a greater tendency to variation than in the wild state. There are exceptions in which these changes are

not all apparent, and it should be noted that species differ greatly in the extent to which they respond to, and are altered by, domestication. Sometimes the changes induced in appearance and characteristics have been comparatively slight, as in the case of the camel, the elephant, and the ostrich; while in other cases they have amounted to the evolution of forms which in a wild state would be regarded as new species.

As a rule, the species which under domestication have proved most useful to man have possessed high fertility, giving numbers, and marked tendency to variation, giving opportunity for improvement and development in some particular direction by selection and breeding. These are prime requisites to rendering a species of great adaptability and usefulness; and the absence of them in some has restricted the scope of their usefulness. The camel, e.g., appears in its native state to have possessed qualities which suited it admirably to man's uses in a rather limited region; and, not exhibiting a marked tendency to vary, it has not been changed much by man, nor have any traits been artificially developed to a high degree. His range of usefulness will probably remain in its present bounds and become more and more restricted as civilization advances in the regions where he now finds his greatest usefulness. Cattle, on the other hand, tend strongly towards variation, and breeds showing wide differences in size, tendency to beef production, milk production, and the richness of the milk, have been developed. As between the cat and the dog, the former possesses great fertility and fecundity, but apparently only slight tendency to variation, and hence in all the years that the cat has been domesticated man has not developed from it an animal of much special use beyond that as a pet; while the dog varies so greatly that a number of races have been developed by selection and crossing which differ greatly in character, and many of them have been turned to use in a variety of ways.

Animals differ greatly in their adaptability to domestication. The wild traits seem more firmly stamped on some species than on others. To admit of successful and profitable domestication, they should be of social and docile disposition, and capable of retaining their fertility under changed conditions. Some species will not breed in confinement or become unproductive. This is often due to inability to observe the natural or customary habits at breeding time and is observed in some birds. On the other hand, hybrids are more readily produced under domestication. See **BREEDING**.

Classes of Domestic Animals. The domestic animals practically all belong to the classes of mammals or birds. The larger number and the more important of the former class are herbivorous and are kept for their flesh, milk, wool or hair, hide, etc., or as beasts of burden, some species, as cattle, being kept for all of these purposes. The most common of the herbivora are cattle, sheep, goats, the buffalo, yak, reindeer, camel, llama, alpaca (ruminants), and the horse, ass, hog, and elephant (pachyderms). The zebra has been tamed and domesticated to some extent; but, like the elephant, no domesticated race of the species exists. Although the elephant has been much employed for many ages for various purposes in India, the individuals are still taken, to large extent, from the wild denizens of the forest, and this animal can only

be said to be half domesticated. The mule, a very important and valuable work animal, is not a distinct species, but a hybrid, the product of the male ass and the mare, resembling the ass much more than the horse; and the hinny, or muto, is the product of the stallion and the she-ass, possessing many of the characteristics of the horse. Both of these animals are incapable of reproduction.

Of carnivorous quadrupeds, there are only two which have been generally and individually domesticated—the dog and the cat. These are kept largely as pets and for ornament, although, as noted above, the dog has been bred and trained to many uses, such as herding cattle and sheep, protection of life and property, hunting, and as a beast of burden. Certain species of foxes are kept under domestication in Alaska and bred for their fur; they become tame, but cannot be reckoned among domestic animals in a restricted sense. A long list of other quadrupeds are tamed and kept as pets and partially or individually domesticated. This is true of the rabbit, guinea pig, ferret, and mungoes, e.g., which are also useful under some conditions. The Belgian hare has recently been kept and bred quite extensively in a number of countries for its flesh.

Of birds, the most important of the domesticated species are gallinaceous—the common barnyard fowls, of which there are many widely different varieties, the guinea hen, and the turkey; to which should be added ducks, geese, and swans, which belong to the web-footed water birds. Pheasants, peacocks, and pigeons are thoroughly domesticated, being kept principally for ornament, although the breeding of them is something of an industry. The ostrich has for some time been kept in confinement in Africa, and more recently in California and Arizona, where quite large ostrich farms are operated on a commercial scale. The birds pair, lay eggs, and rear young plentifully under these conditions and may be said to be partially domesticated. Song birds, parrots, and similar birds which are kept as pets, cannot be said to be truly domesticated species, nor can the various hawks and falcons which are used to hunt living prey. The tame fishing cormorants of China hardly come under the heading of domestication, nor can a long list of birds which have largely abandoned their wild habits for an association with man, such as the swallows, swifts, and other species. The same applies to rats, mice, snakes, vermin, etc., which have associated themselves with man for protection and their own advantage. These are not generally classed among domestic animals, although kept by man under quite natural conditions for his pleasure and use; nor are snails, oysters, turtles, etc., to which his care has been extended. These, together with a number of species of useful insects, such as the bee, silkworm, and cochineal insect, are more properly described as *cultivated* than as *domesticated*.

For further details regarding the description and origin of various kinds of domestic animals, see CATTLE; HORSE; SHEEP; FOWL; GOOSE.

DOMESTIC ECONOMY. See HOME ECONOMICS.

DOMESTIC RELATIONS. The legal relations subsisting between the members of a family or household, the law of domestic relations being made up of the rules which define and regulate the rights and duties of these members with respect to one another. The separate grouping of these rules is a matter of convenience rather than the result of an attempt at logical classification. Indeed, every treatise on this topic contains a large amount of material that is taken bodily from the law of agency, of contract, and of tort. In other words, the law of the domestic relations is not in all its parts a distinct and independent branch of the law, but is made up in large part of legal rules from other branches of the law. As thus conceived, it forms a part of the law of persons, in which the ordinary legal relations are varied by the abnormal status of persons under the various degrees of disability or of legal privilege to which the members of a family are subject. But it also includes the rights arising out of the status of the various family relations, as marriage and divorce, the rights of children against their parents, and the like. The topics ordinarily discussed under this general heading are those of husband and wife, parent and child, guardian and ward, master and servant. It is admitted that the last of these topics, covering as it does the contract relations of employer and employee, carries the discussion far beyond the limits of the modern family or household. For this reason some recent writers on domestic relations have dropped this topic entirely, or limited their consideration of it to the rights and duties of domestic servants. The attempt has been made in some States to codify the rules applicable to this subject. This has been done in New York by a statute known as the Domestic Relations Law. Its scope is fairly indicated by the headings of its various divisions, viz.: Unlawful Marriages; Solemnization, Proof, and Effect of Marriage; Rights and Liabilities of Husband and Wife; The Custody and Wages of Children; Guardians; The Adoption of Children; Apprentices and Servants. See Gilbert, *Domestic Relations* (Albany, 1902); Rodgers, *Domestic Relations* (Chicago, 1899); Schouler, *Domestic Relations* (Boston, 1905); Long, *Domestic Relations* (St. Paul, 1905); Laws of New York, chap. 272 of 1896. See also the articles GUARDIAN; HUSBAND AND WIFE; MASTER AND SERVANT; PARENT AND CHILD, and the authorities mentioned under each of these titles.

DOMESTIC SCIENCE. See HOME ECONOMICS.

DOMESTIC SERVICE. By domestic service is meant the work done in and about the house to provide for the physical comfort of its occupants. It includes the labor of housekeepers, cooks, laundresses, chambermaids, waitresses, nurses, butlers, coachmen, footmen, garden-

ers, choremen and charwomen, and personal attendants.

The condition of household service in different countries varies according to the remoteness of the countries from the feudal state of society and industry. Where the social organization remains aristocratic, there is a class bred more or less definitely to service, at least as to mental attitude. Where democratic conditions prevail, there is no such class. Yet the relation between employer and employed in domestic labor, even in democratic countries, has not resolved itself as it has in other industries. The personal element remains, as between the feudal baron and his retainers. The work is done with all the waste of energy and material attendant upon individual effort as opposed to coöperation. The industry is altogether in an involved transition state.

In ancient times the work of the household was done by slaves. In modern times it has been very largely done by the women of the household and by women employed by them as helpers. To the former fact is largely due the stigma of social inferiority attaching to domestic service and to the latter its uncertain standing as an industry.

The social status of the household servant is everywhere about the same; but as the democratic form of government is approached, the social inferiority which service involves becomes more and more dreaded and despised, and the marks of it more abhorrent to the servant. For instance, it is often difficult to persuade a maid or a nurse in the United States to wear a cap, and English women servants are beginning to protest against that badge; while German and French ones seem, on the contrary, rather proud of their uniforms.

Except where there is a contract specifying other terms, domestic servants in England are hired by the year. Their wages are payable quarterly. Their master is bound to find them suitable lodging and board. The contract, once entered upon, can be terminated only by a month's notice on the part of the servant or the payment of a month's wages on the part of the employer. Immediate dismissal may follow the discovery of immorality, theft, disobedience, extreme inefficiency, or permanent disability. The employer may not legally keep back money from the servant's wages for any breakage, damage, or loss on the part of the servant.

In Germany a two weeks' notice is sufficient to end the service. The employer there is obliged, at the termination of a servant's employment in his house, to register with the police authorities a letter defining the record of the employee while in his service. This is filed in the police book; and as premiums are paid by masters and mistresses for the servants having the best police-book records, it becomes a matter of moment to the servants to maintain good ones. The objection to this system is that the records are not always entirely accurate, although great care is exercised in the matter by the authorities and strict rules are made to govern it. Most of the German servants are drawn from the peasant class, coming from the country to the provincial towns and thence to the large cities.

In France and Italy conditions do not greatly differ from those of Germany, except that the police-book system is not used. In France more men are employed for household work, and there

is less waste than in any other country. Italy and Spain approach more nearly to the feudal system of domestic service.

In Russia, in the country regions, the feudal system prevails. For a piece of land—about two acres—out of the estate, one cow, and the privilege of raising as many pigs and chickens as the serving family desires, a landed proprietor may obtain whole villages of retainers, the services of all of whom are his at his need. In St. Petersburg most of the household servants are Finns. Here also enough of the feudal system remains to make it no uncommon thing for a servant to remain 20 years in one family's employ.

In the United States the earliest white servants were the transported convicts and the redemptioners. The redemptioner's services were sold for a term of years to a colonist, either by himself, by one of his creditors, or by the captain of the vessel in which he took passage. In addition to the servants from these two classes there were slaves, both Indian and negro.

This state of domestic service lasted through the Colonial period to the time of the Revolution, when indented service was replaced in the North by free labor and in the South was entirely superseded by negro slavery.

From the Revolution until the middle of the nineteenth century the servants in the North, except in the great cities, were the social equals of their employers, as is still the case in many parts of the West and Middle West. It was in deference to this equality that the use of the word "servant" was abandoned and that of "help" substituted. All suggestion of servitude was abolished. Liveries, even caps, were not worn. The "help" sat at table with their employers, called the members of the family by their Christian names, and were, in fact, what their name implied—friendly assistants, salaried but independent. This condition of domestic service in the North lasted almost as long as the patriarchal state of slavery in the South.

About the middle of the nineteenth century a change in the state of affairs throughout the United States began with the flood of immigration. The famine of 1846 in Ireland, the German revolution of 1848, and the conditions preceding and following it, and the Treaty of the United States with China in 1844, loosed upon this country an unprecedented number of foreigners. Of the Irish and German immigrants, nearly one-half were women. They entered as "unskilled laborers." The household industries have always been sought by unskilled labor. In the East these immigrants entered at once into the serving class. In the West, along the Pacific coast, the Chinese became the competitors of the natives in household labor, working more cheaply and more skillfully and rapidly displacing such Americans as were engaged in domestic service. These conditions have been somewhat modified by the restrictions on Chinese immigration.

The question of domestic service in the South has been a vexed one since the Civil War. The negroes, long held in servitude and unaccustomed to think for themselves, were suddenly loosed upon the community and given the same rights and privileges as the whites without knowledge of how to use them. The habit of submission did much to restrain them, and their inherent tendencies have prevented them from organizing to any great extent. Many of

them have come North to compete with the immigrants: but this has had no marked effect upon the conditions of domestic service, nor until recently have many white servants been employed in the South. Those who remained in the South have many of the faults of the slaves, with an independence which makes them insusceptible to control; but time, patience, and education are bettering these conditions.

The foreigners in the East found the field ready for them. The women in New England who had in the early days acted as "help" in their neighbors' homes were entering the recently established factories in large numbers. In the early times each household had raised not only its own food products, but its own clothing stuffs as well. The home had been cotton and woolen mill, dressmaking and tailoring shop. The development of machinery took this class of work out of the house, and many of those who had been accustomed to do it in the house followed it to the mills. It was a more remunerative and more independent occupation than household labor, even under the free and equal régime. The Northern women are glad to give over the household labor to the immigrants, but set themselves the difficult task of adapting European methods to American conditions. With increased wealth came the desire for display, and the patterning of household after foreign usage. The result word "servant" came again into use, and domestic service sank in the social scale, while at the same time the immigrants themselves were eagerly imbibing the democratic ideas of their adopted country.

The foreigners have remained practically in control of the American kitchen ever since they took possession of it. According to the reports of the Immigration Commission, the negroes represented nearly 27 per cent of all female servants in 1900; the foreign born, 26 per cent; the native white of foreign parentage, nearly 20 per cent. In cities of population over 50,000 the foreign-born whites provided 44 per cent of the female servants; the negroes, 22.8 per cent; the native born of foreign parentage, 20.3 per cent. In the lesser cities and the country, negro servants represented 29.4 per cent; foreign born, 16 per cent, and native white of foreign parentage, 19.5 per cent. The Irish and Germans contribute the largest quota to the foreign-born servants, 39.5 and 17.4 per cent respectively.

In the farming districts of the Northern and Western States the old conditions of equality above mentioned still prevail. The farmers' wives do their own work, with the help of a "hired girl," and the farmer employs for his field work and chores a "hired man." Both of these are practically members of his family and his social equals, as they are often sons and daughters of his neighbors. Household servants are found mainly in the large cities, partly on account of the congregation of wealth there, and partly on account of the servant's rooted objection to the country—an objection which is doubtless partly due to the foreigner's desire not to be completely isolated from all her kind as well as from her home.

In England and on the Continent wages are much smaller for household labor than in the United States. Four dollars a week, which is lower than the Western and only a little higher than the Eastern average, is a phenomenally

high rate there. In addition, in some parts of the Continent, servants are not necessarily boarded from their employers' tables, and the English may or may not be, as the agreement specifies. "Board wages" are paid instead, and they are very small, sometimes not more than 20 cents a day. Even when food is provided by the employer, it is not likely to be of the same variety as that which serves his own table. "Beer money" and "tea money" are generally stipulated for in English contracts. But the European servants, even in small establishments, have a means of revenue which only the servants of the wealthy or of corporations have here. Tips from guests are a recognized source of income; and the German maid, e.g., lighting a caller to the front door of a modest apartment house in Berlin, would feel defrauded unless she received her small fee.

The advantages enjoyed by household servants in this country are many. They are generally lodged more comfortably than they would probably be otherwise. Numerous as are the complaints against "the girl's room" of a small establishment, it is usually moderately comfortable. The food is generally good. The wages, considering that lodging, light, heat, board, car fare, and expensive dress are not to be provided from them, are much better than shop and factory wages and do not compare badly with the salaries of teachers. On the other hand, household servants have practically no chance to rise in their occupation; they are isolated, both industrially and socially. They have almost no personal freedom, and their standing is regarded as lower than that of other women workers.

Mistresses complain of the uncertainty of the whole situation; there is no fixed rate of wages, no fixed term of service, and no fixed standard of excellence.

Various remedies have been suggested to meet these difficulties, none of which have proved entirely adequate. Some advocate a return to the more patriarchal system of the past and believe in making the relations between mistress or master and servant a more personal one. Some have advocated a "shift system" for servants—setting each to work for only eight hours, and then relieving him or her by another. This plan has been successfully adopted in Chicago by a very rich woman. It would, in its present form, be possible only to the very wealthy, or to an organization of some sort.

Others advocate the abolition of all individual domestic labor. The "Beaconsfield Scheme" for the children, with its common kitchen and dining rooms for the adults, seem to them to solve the problem. This, the cooperative housekeeping scheme, has been often tried and generally with a signal lack of success. The failures, however, seem to have been due rather to mismanagement or to too sweeping and hurried changes than to any inherent impossibility in the plan. Thus, though one of the first arrangements of this sort tried in America, at Cambridge, Mass., in 1871, was not a success, a similar effort on a modified plan, in Brookline, Mass., 25 years later, has not been a failure. This is the Beaconsfield Terrace Scheme—a business affair, rather than a sociological experiment, in intention. The residents of the terrace have, in addition to their own yards, an inclosed park in common. They share tennis courts; a casino, where any one of them may entertain on a

larger scale than in his own home; the services of a choreman; the time of a superintendent of the buildings; and so on. Their heat is supplied from a central steam room and not from individual furnaces. The difficulty, with coöperative housekeeping is that most persons instinctively object to it on the ground of lack of privacy. They feel that they will be deprived of their homes and given instead an improved boarding-house system, and that under these conditions their children cannot develop properly. Many, too, see in such plans danger of being victimized by "cranks" and people of uncertain social views.

Some of those who look forward to the amelioration of domestic service believe that it will be brought about by the establishment of training schools for household servants. So far, however, industrial training schools have received little patronage from the class for whom they are intended. The servants themselves fail to perceive the importance of training, since they can obtain good wages without it, and their ambition is not stimulated by the possibility of rising in the social scale through such training.

In England some schools designed and endowed to prepare girls for household service have become sewing and dressmaking schools, under the dislike of the girls and their parents for household labor. In Belgium schools of industrial training have been instituted by the government and are run under government inspection and control. They have succeeded much better than the private enterprises of other countries, although they are for general household training and not specifically for that of servants.

Profit sharing has also been tried in the household and has on the whole proved successful. The plan is to set aside a certain amount for housekeeping and divide what can be saved out of it between the mistress and the servants in accordance to a proposition previously agreed upon. This, of course, gives the servants an interest in the welfare of the household and has the same advantages and disadvantages as a similar system in business.

Another solution for the domestic-service problem lies in the modern tendency towards specialization. Many kinds of work formerly done in the house, under the supervision of its mistress, are now provided for outside of it. Trained workers take up some special branch of household labor and contract for it with a number of families. It does not appear as yet that specialization will solve the problem altogether.

The servants' unions which have been organized have not yet accomplished anything serious. Nevertheless, it is the opinion of almost all students upon this subject that along this line—the organization of the industry upon a practical business basis, with a regular scale of wages for various grades of skilled and unskilled work, with fixed hours for work and the stigma of servitude removed—lies the hope of betterment. Such a system would necessitate proper training on the part of those who wished to share in the benefits of the organization and many concessions on the part of employers.

Bibliography. Salmon, "Domestic Service," which contains a bibliography, in *Eleventh United States Census Report* (Washington, 1892-94); Baylis, *The Rights, Duties, and Relations of Domestic Servants* (5th ed., London,

1896); id., *Domestic Servants and the Law* (ib., 1906); Graham, *Master and Servant* (ib., 1899); Adams, "A Belated Industry," in *American Journal of Sociology*, vol. i (Chicago, 1896); Walker, *The Wages Question* (New York, 1886); Schloss, *Report on Profit-Sharing* (London, 1894); Herrick, *Expert Maid Servant* (1904); *Reports of the Immigration Commission*, especially vol. 28 (Washington, 1901-12); Casswell, *Law of Domestic Servants* (London, 1913).

DOMETT, ALFRED (1811-87). An English poet and colonial statesman, born at Camberwell Grove, London. He studied at St. John's College, Cambridge, in 1829-33 and in 1837-39 contributed to *Blackwood's* several poems, of which the best known is "A Christmas Hymn." In 1841 he was called to the bar and in 1842 went to New Zealand as one of the earliest settlers in that colony. There he held many public offices, including those of Civil Secretary (1851), Commissioner of Crown Lands and Resident Magistrate at Hawke's Bay (1853-56), and Prime Minister (1862-63). In 1871 he returned to England, and was created C.M.G. in 1880. He is the subject for Browning's poem "Waring." Browning's "The Guardian Angel" also addresses him. His publications include *Ranolf and Amohia: A South Sea Day Dream* (1872) and *Flotsam and Jetsam* (1877). Consult Gisborne, *New Zealand Rulers and Statesmen* (London, 1897).

DOMETT, SIR WILLIAM (1754-1828). An English admiral. He entered the navy in 1769, was made lieutenant in 1777, and during the American Revolution took part in various engagements with the French and Americans. He was appointed captain of the Baltic fleet in 1801 and then of the fleet off Brest. He was made K.C.B. in 1815, G.C.B. in 1820, and admiral in 1819.

DOMEYKITE, dô-mă'kit. A copper arsenide occurring in massive forms, with a metallic lustre and white to gray in color. It occurs in Chilean mines, also at Zwickau in Saxony, and in the copper deposits of Michigan. Domeykite derives its name from the Chilean mineral Domeyko.

DOMICILIA. See **LORX**.

DOMICILE (Lat. *domicilium*, from *domus*, house). The legal residence of a person. Though used in common speech as synonymous with "home" or "place of abode," in the strict legal sense "domicile" denotes the place which the law will hold to be a man's residence; and this may or may not coincide with the place where he in fact usually or habitually resides. It is a doctrine of modern law that every person shall have a definite location in some jurisdiction, to which his legal rights and obligations may be referred, and by which his legal status, public and private, is determined. The name and the notion of domicile, as well as the necessity for it, are comparatively recent and arise from the modern conception of law as being of territorial rather than of personal obligation. Formerly the important question was that of nationality, it being conceived that every person was entitled to be judged and to have his rights and obligations determined by the law of his national allegiance rather than by that of his actual domicile. But the complete triumph of the principle that the authority of a state extends to every one within its borders, irrespective of his nationality or citizenship, and that it is in the main confined to

those limits, has given a new importance to the question of domicile.

As the private and local law by which a person is governed, as well as his political status, now depends almost entirely on his domicile, the question what facts of residence and intention shall determine the domicile has been extensively discussed by the courts and law writers. The importance of the subject in international law has called for its especial consideration by the authorities in that field of jurisprudence.

Vattel defines domicile as habitation fixed in any place with an intention of *always* staying there. This definition is now regarded as too limited by most authorities on international law, certainly by the best writers on the subject in the United States. It is held that in a newly settled country, like the United States, absolute permanence of residence is rare, and it is sufficient to constitute a domicile that the habitation be fixed without any present intention of removing therefrom. Justice Story says: "Two things must concur to constitute a domicile—first, a residence, and, second, the intention of making it the home of the party"; to which Dr. Woolsey adds: "And when once a domicile is acquired it is not shaken off by occasional absences for the sake of business or pleasure, or even by visits to a former domicile or to one's native country." It follows that the same person may be a citizen of one country, possess a domicile in another (for the questions of domicile and citizenship are quite distinct), and temporarily reside in still a third. Another American authority, Wharton, distinguishes three kinds of domicile: domicile by birth, by choice, and by operation of the law; and this classification is now generally accepted. The first is determined by the place of nativity, the second is acquired by a man's own volition, and an illustration of the third is the domicile of a wife, being that of her husband acquired by her at the time of marriage. A child, of course, has the domicile of his parents and is considered incapable of changing his domicile of his own accord, but he follows any change in the domicile of the parents. When the father of a family dies, the domicile of his children and widow continues to be that of his last residence until a new one is acquired in any of the ways already indicated. The question, what amounts to a sufficient intention of permanent residence to cause an immediate change of domicile, is one of no little difficulty, which must be determined by the special facts of each case.

In its relation to private rights and obligations the rule may be laid down in a general way that the law of the place of domicile governs in contracts relating to personal property and in the matter of wills and bankruptcy; while, on the contrary, in matters relating to real estate the law of the place of its situation (*lex rei situs*) prevails. In England it was formerly held that it was necessary to the validity of a will that it should be executed according to the law of the testator's domicile, no matter where the will was drawn; but statutes now provide that the will is valid if executed in accordance with the law of the country where it was made, even though it do not conform to the law of the place of permanent and recognized domicile. Similar provisions exist in most or all of the States in the Union. See CONFLICT OF LAWS.

The question of domicile is often of importance in determining property rights in time of war. Thus, it is held that the property of an alien domiciled in a country with which his own nation is at war is subject to seizure as that of an alien enemy. Under a strict construction of the common law, also, an alien cannot (regardless of the existence of war or peace) hold land, either by purchase or inheritance; but in many of the American States this rule has been directly abolished by statute as opposed to the natural policy of this country, and in others it has become obsolete by general consent. (See ALIEN.) Under the Roman or civil law it was considered that a man might legally hold two domiciles, as when he resided part of the year in one place and part in another, or when he maintained two businesses in separate places; but, as has been explained above, the modern law of Europe and America has no room for this conception. In matters of taxation and in the application of the poor laws the term "domicile" is often used, sometimes loosely, and its definition is often of importance in deciding such matters; the courts will often in treating such questions give the word the more restricted meaning that is attached to the words "dwelling-place," "home," and "residence." It has been held by several American courts that the domicile of a sailor is the place where he voluntarily spends most of his time when on shore. See ALLEGIANCE; CITIZEN; SUBJECT.

The most important authorities are Dicey, *The Law of Domicile* (London, 1879); id., *Conflict of Laws* (ib., 1896); Round, *English Law of Domicile* (ib., 1861); Westlake, *Private International Law* (4th ed., ib., 1905); Moore, *Digest of the International Law of the United States* (Washington, 1903); Stocquart, *Studies in Private International Law* (Brussels, 1900); Bentwich, *Law of Domicile in its Relation to Succession* (London, 1911); Jacobs, *Treatise on the Law of Domicile* (Boston, 1912).

DOMINANT (from Lat. *dominari*, to rule, from *dominus*, lord; connected with Gk. *δᾱμᾱν*, *daman*, Skt. *dam*, to subdue, OHG. *zam*, Ger. *zahn*, Icel. *tamr*, AS. *tom*, Eng. *tame*). In music—1. The fifth tone of the scale. 2. *Dominant chord*, the triad upon the fifth degree. So in the key of C it is g-b-d. It is always a major chord in both major and minor keys. 3. *Dominant seventh*, a chord obtained by adding a minor seventh to the dominant triad. Its resolution is determined by the third, which, being the leading tone (q.v.) of the scale, moves a half step upward; and the seventh, which always descends a half step. In the key of C the dominant seventh is g-b-d-f; the resolution, g-c-e. 4. The *key of the dominant* is the one most closely related to the tonic key. Next comes the key of the fifth below or subdominant. All the tones of the scale can be regarded as component elements of these three fundamental chords, thus:

DOMINANT AND RECESSIVE. See MENDEL'S LAW.

DOMINE QUO VADIS, dō'mē-nā kwō vā'dēs. A small church on the outskirts of Rome on

the Appian Way, named from the tradition that, when Peter was fleeing from persecution in Rome, he was met at this place by Christ going towards the city. Peter, astounded, asked, "Domine, quo vadis?" ('Lord, whither goest thou?') The Saviour answered, "To Rome, to be crucified again"; and the Apostle in shame retraced his steps to the city. In the church is shown a stone bearing an alleged footprint of Christ.

DOMINGO, dô-mên'gô, SAN or SANTO. See SANTO DOMINGO.

DOM'INIC, SAINT (1170-1221). The founder of the Order of Preaching Friars (*Fratres Prædicatorum*) in the Roman Catholic church. He was born at Calaroga, in the north of Spain, probably of the illustrious Guzman family. He studied theology in Palencia and in 1195 became canon of Osma in Castile. With his superior, Diego d'Azevedo, Bishop of Osma from 1201, he made several journeys, one as far as Denmark. On their way back to Spain from a visit to Rome they found at Montpellier three papal legates debating on the means to be adopted for the suppression of the Albigensian heresy, and recommended as the most efficient means the setting of a notable example of humility and self-denial. Dominic, with his Bishop, began to preach throughout Languedoc, and in the following year founded at Prouille his first institution, an asylum for poor girls who were in danger of changing their faith through the inducements held out by the rich and powerful adherents of the new belief. There has been much discussion as to his part in the crusade of extermination against the Albigenses headed by Simon de Montfort after the murder of the papal legate, Peter of Castelnau. The truth seems to be that his activity was limited to prayer for the success of the Catholic arms, and urgent labor for the conversion of the people. From 1215 his life was spent in arduous work in connection with the order which he founded in that year. (See DOMINICANS.) After holding the second general chapter of the order at Bologna in 1221, he had made up his mind to preach the gospel among the heathen Cumans, a Ugric tribe in Hungary, and, if possible, to gain the crown of martyrdom; but he died on August 6, at . . . his body is buried in the church . . . Pope Gregory IX canonized him in 1234. Consult: The original Life by Jordanus, *De Principiis Ordinis Prædicatorum*, ed. J. Berthier (Freiburg, 1892); Lacordaire, *Vie de Saint Dominique* (Brussels, 1841; Eng. trans., London, 1883); Drane, *The Life of St. Dominic* (3d ed., London, 1891); Herkless, *Francis and Dominic* (New York, 1901); Guiraud, *Saint Dominic* (Paris, 1901; Eng. trans., New York, 1901).

DOMINICA, dô-m'i-nē'kâ. A West Indian island lying in the Leeward group, between the French islands of Guadeloupe (on the north) and Martinique (on the south), being distant from each about 30 miles (Map: West Indies, G 4); it constitutes a presidency of the British Leeward Islands colony. Dominica is 29 miles long and 16 miles broad and has an area of 291 square miles. The island is picturesque and very mountainous; the highest point is Morne Diablotin (4747 feet) in the northwest; in the southeast is Morne Trois Pitons (4672 feet). The volcanic nature of the island is manifest in solfataras, thermal springs, subterranean vapors, and the famous

boiling lake. This lake, of unknown depth, lies on the side of Grande Soufrière at an elevation of 2300 feet; it is about 6 miles south of Morne Trois Pitons and about 7 miles east of Roseau. The climate is healthful. The soil is rich and well watered and produces coffee, cacao, numerous vegetables, spices, and limes and other tropical fruits. About 65,000 acres are under cultivation. Sugar, once the staple industry, is no longer of importance. The hills abound in valuable timber. In 1910 imports were valued at £147,322 and exports £112,111; in 1911, £164,695 and £124,678 (chiefly limes and lime juice, citrate of lime, and cacao). There is no railway or internal telegraph; there is a government telephone system of 425 miles. Telegraphic cables connect with Guadeloupe and Martinique. Local government is administered by an administrator, aided by an executive council of six members. Prior to 1898 the Legislative Assembly was partly elective, but in that year, upon its own initiative, the Assembly was made to consist of six officials and six nonofficials, all appointed by the Governor of the Leeward Islands. The Assembly elects two members to the Colonial Legislative Council at St. John (Antigua). In 1911-12, revenue and expenditure, £44,054 and £38,794. The population in 1881 was 28,211 (including 309 Caribs); 1891, 26,841; 1901, 28,894; 1911, 33,863 (including about 420 Caribs, of whom 170 were estimated as of pure blood). The majority of the inhabitants are negroes and Roman Catholics; about two-thirds speak a French patois. The capital is Roseau (pop., 6577), a fortified town and port on the southwest coast. Dominica was discovered by Columbus in 1493, on November 3, a Sunday (*dies dominica*, 'the Lord's day,' whence its name). It was included in the grant made by Charles I in 1627 of various Caribbean islands to the Earl of Carlisle, but the first settlers were French (1632). The treaty of Aix-la-Chapelle (1748) provided that the island, along with some others, be neutral and remain in the possession of the native Caribs. But French planters, with negro slaves, established themselves in increasing numbers, and the island came under the rule of a French governor. It was captured by the British in 1756, and British and French authority alternated until 1783, when British rule was definitely established. A French invasion occurred in 1795 and another, under General La Grange, in 1805, the latter being the most memorable event in the history of the island. In 1833 Dominica and the other British Leeward Islands were formed into a general government under a governor in chief resident in Antigua, and under an Act of 1871 it became a presidency of the Leeward Islands colony.

DOMINICALE, dô-mîn'i-kâ'lê, or **DOMINICAL** (ML., from *dominicus*, relating to the Lord, from *dominus*, lord). A rare term, probably denoting a white linen cloth in which at communion, during the early ages of the Western church, women received the sacred host ("the body of the Lord," hence the derivation), which as late as the eighth or ninth century was placed in the hand of the communicant, not in the mouth as in modern Roman Catholic usage. It is sometimes applied to a veil worn by women in church.

DOMINICAL LETTER, or **SUNDAY LETTER**. One of the seven letters A, B, C, D, E,

F, G, used in calendars to mark the Sundays of the year. The first seven days of the year being marked in their order by the above letters, the following seven, and all consecutive sets of seven days to the end of the year, are similarly marked: so that the 1st, 8th, 15th, 22d, etc., days of the year are all marked by A; and the 2d, 9th, 16th, 23d, etc., by B; and so on. The days being thus marked, it is evident that, on whatever day the first Sunday of the year falls, the letter which marks it will mark all the other Sundays in the year, as the number of the letters and of the days in the week is the same.

As the common year consists of 52 weeks and one day over, the dominical letters go backward one day every common year. If the dominical letter of a common year be G, F will be the dominical letter for the next year. As a leap year consists of 52 weeks and two days, the letters go backward two days every leap year. If in the beginning of a leap year the dominical letter be G, E will be the dominical letter for the next year. This extra retrocession, however, is made to take place at the intercalary day (the 29th of February) by the artificer marking it by the same letter as the day which preceded it, and thus the next Sunday is marked by the letter preceding that which marked the Sundays before the intercalary day. Suppose the 28th of February in a leap year to be a Sunday, and marked by F, it is evident that the dominical letter for the rest of the year will be E. In the Catholic ecclesiastical calendar February 24, instead of 29, is counted twice. As every fourth year is a leap year, and the letters are seven in number, it is clear that the same order of letters must return in four times seven, or 28 years, which would, but for the leap years, recur in seven years, and hence the solar cycle. (See PERIOD.) The Romans divided the year into *nundinae*, periods of eight days each, marked by the first eight letters of the alphabet. When, in the time of Augustus, the week of seven days was introduced, the first seven letters only were needed. The device was useful to the Christian as a means of determining the day of the month on which a feast falls in any year. (See EASTER.) Rules and tables for finding the dominical letters are given in prayer books, breviaries, etc., as well as in works on dates. Consult Woodman, *Perpetual Ecclesiastical Calendar* (New York, 1906).

DOMINICAN REPUBLIC. See SANTO DOMINGO.

DOMINICANS, or ORDER OF PREACHERS. An order of preaching friars (the Latin name is *Ordo Prædicatorum*) in the Roman Catholic church. It was founded by St. Dominic (q.v.) in 1215, for the purpose of counteracting, by means of preaching and teaching, the tendency of the times to break away from the church. When in Rome seeking confirmation for his order, which was delayed on account of the opposition of the Fourth Lateran Council, just concluded, to the multiplication of new religious organizations, the founder met St. Francis of Assisi, who was engaged in a similar work. A cordial friendship sprang up between the two men, different as they were in temperament; to this day its memory is preserved in the custom of the priests of each order celebrating the feast of the founder of the other in his own church. Both orders differed from the older ones in

emphasizing more strictly the spirit of poverty and rejecting the possession of even community property. Hence they are called mendicant orders, as they originally depended for their subsistence entirely on the daily charity of their neighbors. The name of monks is often incorrectly applied to them; the proper designation of both Franciscans and Dominicans is friars (Lat. *fratres*, 'brothers'). The requisite papal confirmation was obtained from the new Pope, Honorius III, at the end of 1216; with it went special privileges, especially the right to preach and hear confessions everywhere, without local authorization. The first house of the order was at Toulouse, from which in the summer of 1217 Dominic sent some of his 16 associates to spread the movement in Spain and France. From the name of their first convent of Saint-Jacques in Paris, they were popularly known in the latter country as Jacobins—a name which was to acquire a new and sinister significance in the Revolution. They were introduced into England within six years and founded a house at Oxford. Here they were known as "Black Friars," from the habit which they wear outside the convent, in preaching and in hearing confessions—a black cloak and hood over a white woolen tunic. "The monks," writes Matthew Paris, a Benedictine, "did not in three or four hundred years ascend to such a height of greatness as the friars minor and preachers, within 24 years after they began to build their first house in England." (Consult Jessopp, *The Coming of the Friars*, London, 1888.) Their progress was scarcely less rapid in Scotland, where they found a munificent patron in King Alexander II, who is said to have met St. Dominic in Paris. They soon spread as far as Russia and Greece and in 1280 even to Greenland.

In accordance with the declared purpose of their foundation, the Dominicans have always been known as diligent preachers and strenuous combatants against any departure from the teaching of their church. In this capacity they were intrusted with the conduct of the Inquisition as an ecclesiastical institution, and even in Spain, after it became practically a department of civil government, a Dominican was usually at its head. The office of master of the sacred palace, endowed with great privileges by Leo X, has always been held by a member of the order, and since 1620 the censorship of books has been one of its functions. In 1425 the permission to hold property was granted by the Pope to certain houses, and extended to the entire order in 1477, since which time they have been less exclusively a mendicant order. They have furnished four popes (Innocent V, Benedict XI, Pius V, and Benedict XIII), and more than 60 cardinals. Outside of their specific work, they did much for the development of art. Their cloister at Santa Maria Novella, in Florence, was a veritable school of architecture. Painting was also cultivated with great success at San Marco in the same city and at Santa Caterina in Pisa; and the names of Giovanni da Uesole, better known as Fra Angelico, Benedetto da Mugello, and Bartolommeo della Porta are worthy of remembrance. (Consult Marchese, *Memorie dei più insigni pittori, scultori e architetti domenicani*, Bologna, 1878.) Their chief glory in theological learning is St. Thomas Aquinas (q.v.), whose teaching has been especially commended by Leo XIII as the standard

of dogmatic theology; other distinguished teachers were Albertus Magnus and Raymond of Peñaforte, the third general of the order. Their great rivals in the later Middle Ages were the Franciscans. These two orders divided the paramount influence in the church, and often in the Catholic states, not without frequent hostility on the part of the parochial clergy, who felt their rights invaded by the friars; but the rise of the Jesuits lessened their power both in the schools and in the court. In the eighteenth century they possessed not less than 1000 houses in all parts of the world. The troubles of the latter part of that century, however, decreased their number considerably. In France the order was revived largely through the efforts of the famous Lacordaire (q.v.), the centenary of whose birth was solemnly celebrated in 1902 as that of "the restorer of the Dominican Order in France." In England and Ireland they have 21 houses for men and 13 for women. They played the leading part in the evangelization of Spanish America. Introduced into the United States in 1805, they now have 20 houses for men, while the Dominican sisters have 24 mother houses, each with several succursal houses. At the head of the whole order stands the general (*magister generalis*), whose term of office since 1862 has been 12 years; since 1273 he has had his residence at Santa Maria Sopra Minerva in Rome. There are 52 provinces (each with a provincial at its head), though some of these are now merely nominal.

The female branch of the order may claim, in a sense, greater antiquity than the male, since Dominic founded his house at Prouille in 1206; but after the friars were established, the members of his community modestly called themselves the second order. Another house was founded at Rome in 1218, Dominic being commissioned to unite a number of small or private associations in the authorized system of his rule. The cloister of San Sisto, given him by the Pope for this purpose, is thus really the first in which the Dominican habit was worn by women. The order was originally intended to be contemplative, but in later years, together with some relaxations of the rule, its scope was extended so far as to include the education of girls and other practical works. The nuns are not numerous, since the revolutionary movements of the latter part of the eighteenth century destroyed the greater part of their houses; but a certain number of new convents has sprung up in the nineteenth century, especially in Bavaria. The third order was organized by St. Dominic in 1220, to provide a constant supply of defenders of the church against the assaults of the Albigenses and other turbulent innovators. He gave it the name "militia of Jesus Christ," and pledged its members to defend the church with their arms and their possessions. Married men could not be received into the brotherhood without the consent of their wives, who were bidden to pray for the success of the men. The enthusiasm of the Middle Ages soon brought large numbers, to whom the founder gave a few simple rules for holy living. After the necessity of this militant life passed away, the members were unwilling to dissolve their association and continued it as against spiritual foes, naming themselves "brothers and sisters of penance." Their numbers increasing rapidly, the seventh general of

the order, Munio de Zamora, reduced the rules given by the founder to a systematic form, in which they were confirmed by Pope Innocent VII in 1405 and Eugenius IV in 1439.

Some members have maintained a cloistered life, but the majority have been men and women living a devout life in the world. The third order has produced numerous saints, including St. Catharine of Siena, and the first American saint, Rose of Lima. According to the official Catholic Directory in 1914 there were in the United States and Philippines 242 Dominican fathers, 123 clerical students, and 35 lay brothers. On the history of the Dominicans in general, consult: Caro, *Saint-Dominique et les Dominicains* (Paris, 1853); Danzas, *Etude sur les temps primitifs de l'ordre de Saint-Dominique* (ib., 1874 et seq.); Drane, *The Life of St. Dominic, with a Sketch of the Dominican Order* (3d ed., London, 1891); Proctor (ed.), *Short Lives of the Dominican Saints* (New York, 1901); *Monumenta Ordinis Fratrum Prædicatorum Historia* (Stuttgart, 1900 et seq.). For further details of both Dominican and Franciscan third orders, see TERTIARY.

DOMINIE (dō'mī-nē) **SAMPSON.** A faithful schoolmaster in Scott's *Guy Mannerling*.

DOMINION. A town in Cape Breton Co., Nova Scotia, Canada, 13 miles from the Sydney and Louisburg Railway, and connected by electric railway with Sydney, B. N. S. and Glace Bay. Collieries of the Dominion Coal and Iron Co. are located here. There are an amount and water-works system. The town was founded about 1905. Pop., 1901, 1546; 1911, 2589.

DOMINION, THE OLD. Virginia. See STATES, POPULAR NAMES OF.

DOMINION OF CANADA. See CANADA, DOMINION OF.

DOMINIQUE, dōm'i-nēk. A breed of domestic fowls very similar in plumage to the barred Plymouth Rocks. Both cocks and hens have rose combs and bright yellow legs. They have excellent qualities and weigh from 6½ to 8½ pounds.

DOMINIQUE. See DOMINICA.

DOMINIS, dō'mē-nēs, MARCO ANTONIO DE (1566-1624). An Italian ecclesiastic. He was born on the island of Arbe, on the coast of Dalmatia, and was educated by the Jesuits at Loretto and Padua, winning distinction by his ability and the varied character of his studies. He taught mathematics at Padua and logic and rhetoric at Brescia. He finally refused to become a Jesuit and for several years was a popular preacher. In 1596 he was appointed Bishop of Segni in the State of Venice, and in 1598 Archbishop of Spalatro and Primate of Dalmatia and Croatia. He quarreled with the Pope and, having exhibited certain Protestant leanings, found it expedient to resign his post. In 1616 he went to England and, as a convert from Catholicism, was well received. James I appointed him dean of Windsor and master of the Savoy in 1617. The same year he published the first part of his great theological work, the *De Republica Ecclesiastica contra Primatum Papæ*, in which he endeavored to show that the Pope had no supremacy over other bishops, but was merely *primus inter pares*. He also published in England Sarpi's *Historia del Concilio Tridentino*. For a time he posed as a violent opponent of Catholicism. But in 1620 he began to negotiate a return to his old faith.

He arrived at Rome in 1622 and was well received at first, but a charge of heresy was brought against him in 1623. He was imprisoned in the castle of Saint Angelo and died there Sept. 28, 1624. Being subsequently condemned as a heretic, his body was raised from its grave and burned, with his portrait and books, Dec. 21, 1624. In his *De Radiis Visus et Lucis in Vitris Perspectivis et Iride* (1611), written while he was at Padua, Dominis was the first to approximate to the true scientific explanation of the rainbow. His *Reasons for Leaving the Church of Rome* is translated in Somer's *Tracts*; his *Motives for Renouncing the Protestant Religion* (1623) was published in English translation (1627). Consult *A Relation Sent from Rome of the Process, Sentence, and Execution Done upon the Body, Picture, and Books of Marco Antonio Dominis after his Death* (1624).

DOMINIUM (Lat., lordship). At Roman law, *dominium* meant ownership, or private right over a thing, whether immovable or movable. More precisely *dominium* was the general right, as opposed to any special right, such as servitude or lien. It included the power of use and enjoyment, of alienation and of testamentary disposition; but limitations were, as in modern law, imposed upon the owner in his own interest (e.g., in case of infancy or insanity) or in the interest of neighbors or of the public generally. As regards slaves, restrictions were imposed upon the owner in the interests of humanity. In the technical sense *dominium* was ownership vested by the old civil law (*ex jure Quiritium*), as opposed to the substantially equivalent right created by the later, praetorian, law—a distinction similar to that between legal and equitable ownership in English and American law. (See **CIVIL LAW**; **USES**; **TRUST**.) It was said that the praetor could not grant ownership, but only possession of the *bonorum possessio*, and that the *dominium* remained with the civil-law owner, although his title was a naked one (*dominium nudum*). *Dominium*, at Roman law, was never confused with *imperium*, or sovereignty; and when it was said that the lands of conquered subjects of Rome were in the *dominium* of the Roman people, this meant that, in legal theory, the land was owned by the Roman people, and that the provincials were merely possessors, holding at the pleasure of the Roman people. *Dominium* could be held by two or more persons jointly, but in such case the joint owners (*condomini*) were always coproprietors with similar rights. Ownership could not be so divided that different powers should be attributed to different persons and each be regarded as *dominus*. During the Middle Ages, however, the right of the feudal superior to a fief was described as direct ownership (*dominium directum*), and the right of the vassal in possession was termed beneficial ownership (*dominium utile*). In connection with the base tenures, also, the same terms were respectively applied to the right of the landlord and the right of the tenant. To the supreme feudal lord was attributed eminent domain (*dominium eminens*). These uses of the word *dominium* were due to the feudal confusion of political with proprietary powers, and with the dissolution of the feudal system this ambiguity disappeared; but the term "eminent domain" has been retained to describe the exercise of govern-

mental authority over property, particularly for the purpose of expropriation of the property for public use. By writers on international law *dominium* has been used in the sense of sovereignty, and the whole doctrine of acquisition and loss of sovereignty over territory was worked out by Grotius and his successors, under the head of *dominium*. In this process many rules were derived, by analogy, from the rules of the Roman law . . . isition and loss of ownership. . . . **DOMAIN**; **FEUDALISM**; **PROPERTY**. Consult the authorities referred to under **PROPERTY**; **INTERNATIONAL LAW**; **CIVIL LAW**.

DOMINO. See **MASK**.

DOMINOES (so called, apparently, from the color of the back of the pieces, which is black, like a domino). A game, partly of chance and partly of skill, played by any number of people from two to a dozen, but most often by two, with 28 oblong pieces of ivory, bone, or wood, plain black on the back and white on the front marked with black dots in two divisions on the front, one set of dots on one side of a line dividing the centre, and the other on the opposite side of the line. One of these dominoes is

A DOMINO.

blank on both divisions, the remainder are numbered from double six; i.e., six in each division, down through the scale, 6-5, 6-4, 6-3, 6-2, 6-1, and so on, 5-5, 5-4, 5-3, 5-2, 5-1, through all the other numbers. Before beginning to play, the 28 pieces are turned face downward and shuffled or mixed up on the table so that the position of no special piece can be recognized. Then, according to the particular game about to be played, the whole, or a certain proportion of the dominoes, is selected, one at a time, by the respective players. Each player sets his dominoes up on edge so that they cannot be seen by the opponent, and examines their markings. Whatever dominoes are not drawn form the stock or reserve. The first player places one piece face upward on the table, and his opponent must place against it "a match," i.e., a piece out of his hand corresponding in pips at one end or the other with the piece laid down. Then the first player (in a two game) must in his turn match, or pose, from his hand, a domino to meet the new combination of pips—there being always two ends for him to select to match. If he has no number corresponding to either end, he "passes," and the opponent plays again; or, if he is playing the "draw" game (a game in which less than the whole number of dominoes was originally dealt), he may draw on stock up to, but never including, the last two dominoes. Thus the game goes on until one of the players has put out all his dominoes and can neither "match" nor "draw." The one who has the smallest number of pips on his unexhausted dominoes wins, or, in case of an equality of pips, he who has the fewest

dominoes left wins. The other varieties of the game are the "draw game," and its variation "matador"; "the block game" and its variations; "muggins," or "all fives," "all threes," "Sebastopol," "the Bergen game," "domino pool," and various other miscellaneous games. The game was not known in Europe until the middle of the eighteenth century, but it has spread all over the world. Consult *Foster's Complete Hoyle* (New York, 1909).

DOMINUS (Lat., lord). 1. At Roman law, the owner, the person who holds *dominium* over a thing—including, of course, the master of a slave. 2. In Roman popular speech, a form of respectful address, like our "sir." 3. In the Imperial period, a title given to the Emperor. In the early Empire, however, the use of this title was thought servile, and to demand it or even permit it was considered despotic. See **DOMINIUM**.

In legal phraseology, the *dominus litis* is the person really interested in the issue of an action, though not necessarily the nominal plaintiff (*actor*) or defendant (*reus*).

DOMITIA (dō-mish'i-a) **GENS** (Lat., Domitian family). A plebeian family in Rome, famous under the later Republic. It had two branches—the Calvini and the Ahenobarbi. Of the latter branch, the Emperor Nero was the last male representative.

DOMITIAN, dō-mish'i-an. **TITUS FLAVIUS DOMITIANUS** (51-96), Emperor of Rome from 81 to 96 A.D. He was the son of Vespasian, and younger brother of Titus, whom he succeeded on the throne. The earlier years of his reign were, on the whole, advantageously occupied for the public benefit. Many good laws were passed, the provinces were carefully governed, and justice was rigidly administered. As he grew older, however, his ambition, his jealousy, and his pride, wounded by the failure of his campaigns against the Dacians (who were led to victory by their King, Decebalus, q.v.) and the Marcomanni, and by the revolt of Antonius Saturninus, who commanded the armies in Upper Germany, began to instigate him to the most atrocious cruelties. By murder or banishment he deprived Rome of nearly every citizen conspicuous for talent, learning, or wealth. He won the army by greatly increasing the pay of the soldiers and secured the favor of the people by prodigal largesses and gladiatorial shows and games, in which he sometimes took part in person. His cruelties became at length so intolerable that a conspiracy, encouraged by his wife, Domitia, whom he had doomed to death, was formed against him, and the tyrant was assassinated. Consult Imhoff, *T. Flavius Domitianus* (Halle, 1857), and Gsell, *Essai sur le règne de l'empereur Domitien* (1894).

DOMINUS, POPE. See **DONUS**.

DOMODOSSOLA, dō-mō-dōs'sō-lā (ancient Oscela). A picturesque town at the Italian end of the Simplon Pass, on the Toce (Map: Italy, C 1). The adjacent Mount Calvary, which commands an inspiring view, is covered with small chapels that are visited by many pilgrims. The principal industries are raising fruit, making wine, and the manufacture of silk and leather. Pop., 1901, 5016; 1911, 6421.

DOMRA (a corruption of the Russian *bandurra* from the Gk. *πανδούρα*, *pandoura*, a lyre with three strings). A Russian stringed instrument with a large belly and long neck. From it the balalaika (q.v.) was developed.

Since Anadreef made balalaika orchestras popular in Russia, the domra is built in larger sizes and serves as the bass of those orchestras. Consult A. Faminzin, *The Domra and Related Musical Instruments* (St. Petersburg, 1891, in Russian), and K. Schlesinger, *History of Musical Instruments* (London, 1912).

DOMREMY - LA - PUCELLE, dōn'rā'mē'lā-pū'sēl' (Fr., Domremy of the Maid; so named in honor of Joan of Arc). A village in the Department of Vosges, France, on the left bank of the Meuse, about 7 miles north of Neufchâteau. It is famous as the birthplace of Joan of Arc, whose cottage, adorned with the royal arms of France and those of the family of the heroine, is still in existence. There is a bronze statue of Joan by E. Paul in front of the church. The modern basilica of Le Bois Chenu with a statue of Joan by Allar, on a hill near the village, marks the spot where the Maid of Orléans received the spiritual mission to deliver her country from the enemy. The interior contains mural decorations of the six stages in the life of Joan by J. P. Laurens. The village was freed from all taxes by Charles VII on account of its brave daughter and enjoyed this privilege until the Revolution. A yearly pageant representing the life of Joan is given by the people of the village. Pop., 1901, 308; 1911, 267.

DON. A river of south Russia, rising in a small lake in the Government of Tula (Map: Russia, F 5). It flows in a general southeasterly direction, through the governments of Tula, Ryazan, Tambov, and Voronezh, and, after describing an arc across the Province of the Don Cossacks, where it approaches within 37 miles of the Volga, it enters the Sea of Azov at the town of the same name. Its total length is over 1300 miles, of which 800 are navigable. Its breadth varies between 500 and 1850 feet. In its upper course the Don flows through a low country, which is subject to overflow in the spring. The lower course is through a more elevated region. The chief tributaries of the Don are the Donetz and the Sosna on the west, and the Voronezh, Chover, Medveditza, and Manitch on the east. The Don is connected with the Volga by a canal. The river is very rich in fish; the freight carried by it consists chiefly of grain, lumber, and cattle. The principal port is Rostov. The Don is the Tanais of the ancients.

DON, or DUN. A river of the West Riding of Yorkshire, England, rising in the moors on the borders of Derbyshire and Cheshire (Map: England, E 3). It flows 55 miles, first south-east to Sheffield, and then northeast by Rotherham, Doncaster, and Thorne, to its junction with the Ouse at Goole. Its chief tributaries are the Rother, Dearne, and Wente. It is navigable for the last 39 miles of its course below Sheffield, by the aid of canals.

DON. A river of Aberdeenshire, Scotland, rising in a peat bog on the borders of Banffshire, nearly 2000 feet above sea level, and entering the North Sea a mile northeast of Old Aberdeen (Map: Scotland, F 2). It has a total course of 78 miles. It is noted for its salmon fisheries. Its chief tributary is the Ury.

DONA FRANCISCA. A German settlement in the State of Santa Catharina, Brazil, founded in 1851 by a German colonization society. It covers an area of about 550 square miles and had in 1900 a population of nearly 25,000. Chief town, Joinville, with about 3000

inhabitants. Consult Gernhardt, *Dona Francisca, Hansa und Blumenau drei deutsche Mustersiedelungen im Santa Catharina* (Breslau, 1901).

DONAI, dōn'ī, or **DONNAI**. A river in southeastern French Indo-China, rising in the highlands near the coast in about lat. 12° N. It flows generally towards the southwest, discharging its waters through a delta, which is a continuation of the north outlet of the Mekong. Saigon, the capital of Cochinchina, is on its banks.

DONALDSON, EDWARD (1816-89). An American naval officer. He was born in Baltimore, entered the navy as midshipman in 1835, and became lieutenant in 1847. In 1862, as commander of the *Scioto*, he took part in the bombardment of Forts Jackson and St. Philip, in Farragut's capture of New Orleans, and was raised to the rank of commander. He also participated in the battle of Mobile Bay. He became a captain in 1866, a commodore in 1871, and a rear admiral in 1876, when he was retired from the service.

DONALDSON, HENRY HERBERT (1857-). An American neurologist, born in Yonkers, N. Y. After graduating from Yale University in 1879 he studied at Sheffield Scientific School (Yale), at the College of Physicians and Surgeons (Columbia University), and at Johns Hopkins, where he was instructor in biology (1883-84) and associate professor of psychology (1887-88). He was assistant professor of neurology (1889-92) at Clark University and professor and head of the department of neurology (1892-1906) and dean of the Ogden (Graduate) School of Science (1892-98) at the University of Chicago. In 1906 he became professor of neurology at the Wistar Institute of Anatomy and Biology, Philadelphia. He is the author of *The Growth of the Brain* (1895); "The Physiology of the Central Nervous System," in *An American Text-Book of Physiology* (1896); *On the Weight of the Crania of Norway and Albino Rats* (1912); and articles in scientific journals.

DONALDSON, SIR JAMES (1831-). A Scottish educator and author. He was born at Aberdeen, was educated at Aberdeen University, New College, London, and Berlin University, and was appointed tutor in Greek at Edinburgh University in 1852. He afterward became rector of the high schools of Stirling (1854-56) and Edinburgh (1866-81), where he had previously been classical master for 10 years. In 1881 he was appointed professor of humanity at Aberdeen University, and in 1890 he became vice chancellor and principal of the University of St. Andrews and principal of the United College of St. Salvador and St. Leonard. He was knighted in 1907. His publications include the following: *A Modern Greek Grammar for the Use of Classical Students* (1853); *Lyra Græca*, specimens of Greek lyric poetry, ancient and modern (1854); *Critical History of Christian Literature and Doctrine from the Death of the Apostles to the Nicene Council* (3 vols., 1864-66); *The Ante-Nicene Christian Library*, in collaboration with Professor Roberts (24 vols., 1867-72); *Expiatory and Substitutory Sacrifices of the Greeks* (1875); *Woman: Her Position and Influence in Ancient Greece and Rome, and Among the Early Christians* (1907); *Addresses Delivered in the University of St. Andrews from 1886 to 1910* (1911).

DONALDSON, JAMES LOWRY (1814-85). An

American soldier. He was born in Baltimore, Md., graduated at West Point in 1836, and served with distinction in the Florida and Mexican wars. He was chief quartermaster of the Department of the Cumberland and then of the Military Division of Tennessee during the Civil War, and at its close was brevetted major general in the regular army. He retired from active service in 1869 and resigned from the army in 1874. He wrote *Sergeant Atkins* (1871), a tale of the Florida War.

DONALDSON, JOHN WILLIAM (1811-61). An English classical scholar, born in London. He was educated at the University College, London, and at Trinity College, Cambridge, from which he received the degree of B.A. in 1834. In 1835 he was elected fellow. His first work was as reviser of Buckham's *The Theatre of the Greeks*, which passed through eight editions, but is now antiquated. In 1839 he published his *New Cratylus*, which is remarkable as being the first attempt, on a large scale, to familiarize Englishmen with the principles of comparative philology, as established by Pott, Bopp, Grimm, and others in Germany. Donaldson in 1841 accepted the post of head master of the grammar school at Bury St. Edmunds, having previously taken orders. In his duties as head master, he found time to prosecute his linguistic studies, embracing Hebrew and Arabic and many of the languages of modern Europe. In his *Varronianus*, of which the first edition appeared in 1844, he undertook to accomplish for Latin philology what he had done for Greek in the *New Cratylus*. Among his other works of this period are an edition of Pindar, of the *Antigone* of Sophocles (with a verse translation), *Maskil le Sopher* (a treatise on Hebrew grammar), and finally *Jashar* in 1854, a book written in Latin and published at Berlin, the object of which was, by critical tests, to distinguish the remains of early Hebrew songs embedded in the Masoretic text of the Old Testament. This book was violently assailed by the religious press for its free handling of the text, but reached a second edition.

He resigned his place at Bury St. Edmunds in 1855 and returned to Cambridge. Here he wrote a volume entitled *Christian Orthodoxy*, in answer to the critics of *Jashar*. This also was violently attacked. A smaller volume on classical scholarship followed. He had previously issued a *Greek Grammar* and a *Latin Grammar* for the use of schools. These, during his residence at Cambridge, he recast and enlarged. In 1856 he was appointed one of the classical examiners in the University of London. In 1858 appeared his *History of the Literature of Ancient Greece*, in three volumes, the first two of which are a translation from the German of K. O. Müller. He was engaged in superintending the compilation of a new *Greek Lexicon*, when his health failed. Consult Garnett in *Dictionary of National Biography*, vol. xv (1888).

DONALDSON, THOMAS LEVERTON (1795-1885). An English architect and writer, born in London. In 1811 he entered his father's office, won a Royal Academy medal in 1817, in 1818 began his travels in Italy and Greece, and in 1882 was elected to the Academy of St. Luke, Rome. He was one of the founders of the Institute of Architects, of which he was in 1864 elected president, and from 1841 to 1864 was

professor of architecture at University College (London). He obtained a French medal of the first class in 1855, the Belgian order of Leopold in 1872, and was elected a member of the French Institute. Structures designed by him include University Hall, the Library and Laboratory of University College, London; and the Scottish Corporation Hall. He published: *Pompeii* (2 vols., 1827); *A Collection of the Most Approved Samples of Doorways from Ancient and Modern Buildings in Greece and Italy* (1883); *Handbook of Specifications for Practical Guide to the Architects* (2 vols., 1859); edited a supplementary volume to Stuart and Revett's *Antiquities of Athens*, and collaborated on the Architectural Publication Society's *Dictionary of Architecture*.

DONALDSONVILLE. A town and the county seat of Ascension Parish, La., 64 miles by rail above New Orleans, on the Mississippi River, at the commencement of the Bayou Lafourche, and on the Texas and Pacific Railroad (Map: Louisiana, D 3). It is primarily a commercial centre, with extensive sugar, rice, lumber, and cotton interests. The government is administered by a mayor and two commissioners, elected every four years. The power of recall is vested in the people. The town owns and operates the water works and electric light plant. Donaldsonville was settled about 1760 and was incorporated in 1806. In the battle of Fort Butler, in 1863, Donaldsonville was bombarded and burned by Federal troops, aided by Farragut. The town was almost completely destroyed. Pop., 1900, 4105; 1910, 4090.

DONALITIUS, dön'a-lish'i-us, CHRISTIAN (1714-80). A Lithuanian poet. He was born in East Prussia and, three years after his graduation at Königs-berg, was appointed rector at Stallupönen (1740). He died at Tolmingkehmen, where he had obtained a pastorate in 1743. His poems enjoy high rank among the very meagre products of artistic verse in the Lithuanian language. They include six fables in hexameters. Donalitiu's works were published by Schleicher (1865, with Lithuanian-German commentary); and Nesselmann (1869, with a German translation and a glossary). Another German translation appeared in 1893 (by Passarge, at Halle). Consult his biography by F. Tetzner in *Altpreussische Monatschrift* (1897, pp. 227-331, 409-441; 1899, pp. 305-310).

DON'AR. Teutonic equivalent of the Scandinavian Thor.

DONAT. See DONATUS, AELIUS.

DONATELLO, or **DONATO**, dō-nā'tō (c. 1386-1466). The most important Florentine sculptor of the early Renaissance, who, more than any other, may be considered the founder of modern sculpture. He was born at Florence, probably in 1386, the son of Niccolò di Betto Bardi, a wool comber who had been involved in the uprising of the Ciompi and exiled from Florence in 1378. As he returned in 1380, it is likely that Donatello was brought up in his father's house and not in that of the Martelli (as was traditionally supposed). His mother continued to live with her bachelor son until her death at 80. Nothing is known of his boyhood or first master in sculpture. In a contract of 1403 he is mentioned as among Ghiberti's assistants on the baptistery portals. He was certainly influenced by his association with his friend Brunelleschi (q.v.), the architect, with whom, following Vasari's account, it is

supposed that he visited Rome in the early years of the century to study the ancient monuments. More recent authorities, however, judging from the stylistic qualities of his work, deny this first Roman visit.

Donatello was the most prolific sculptor of the Renaissance, and it will be possible to mention only his principal works. Those executed before 1425 belong to what may be called his formative period, in which he shows strong reminiscences of the Gothic, but with increasing classical and realistic tendencies. Of his marble statues for the exterior of the church of Or San Michele, "St. Mark," executed in 1411-12 for the Linen Drapers, is an admirable figure of noble proportions in an easy position, and set off with graceful drapery. "St. George," completed in 1416 for the Armorers, now in the Museo Nazionale, is the most attractive work of his early period. The face of the youthful hero is strong and gentle; his bearing expresses determination, but without constraint.

During the same period Donatello was occupied with a number of statues for the cathedral of Florence. Among these were "John the Evangelist" (1415), the prototype of Michelangelo's "Moses," and a colossal "David" (1416), now in the Museo Nazionale. These works showed classical tendencies, but at the same time he created others of a pronounced realistic character, as, e.g., the so-called "Poggio" (1412), in the cathedral, and especially in the figures for the campanile, "Joshua" (1412), "John the Baptist" (1416), the so-called "Habakuk," "Jeremiah," and the famous "Zuccone" (Baldhead), erroneously called "David"—an old man of unusual ugliness, though the statue is wonderfully strong and lifelike and was Donatello's favorite. In these statues, excepting the last two, he was aided to some extent by assistants. All show a remarkable knowledge of sculptural perspective. Mention should here be made of the famous sandstone Marzocco (1418-20)—the lion of Florence; of the beautiful marble tabernacle on the exterior of Or San Michele, now containing Verrocchio's "Christ and St. Thomas." The statue of St. Louis, which it formerly contained—his first work in bronze—is now in Santa Croce, where is also the wooden "Crucifix" celebrated in Vasari's anecdote. Mention should also be made of the painted bust of Niccolò da Uzzano, a realistic portrait (the first of its kind in the Renaissance), in the Museo Nazionale, but assigned by some critics to a later period.

The second period of Donatello's art (1425-43) begins with his association with the architect and sculptor Michelozzo, and this date marks the beginning of his second period. Generally speaking, Michelozzo furnished the architectural designs and also assisted in bronze casting, in which his associate was inexperienced. It should be noted, however, that the latter speedily acquired a mastery of decoration, which became of great importance in the development of the Renaissance. Their first joint work was the monument to Pope John XXIII (1425-26) in the baptistery of Florence. Under a marble canopy, with a relief of the "Madonna and Child," lies the bronze effigy of the Pope, by Donatello. Below is the sarcophagus, carved with two angels bearing the inscription. The beautiful marble base contains three statues—"Faith," "Hope," and "Charity," of which the first is by Michelozzo. Of their other joint

DONATELLO

STATUE OF "ST. GEORGE," FROM THE SCULPTURE NOW IN THE NATIONAL MUSEUM, FLORENCE

works, the monument of Cardinal Brancacci, in Sant' Angelo, Naples, and that of Bartolomeo Aragazzi in the cathedral of Montepulciano, were chiefly done by Michelozzo (q.v.). The excellent relief of the "Ascension," of the former, is by Donatello. He also executed other bronze works, which Michelozzo cast for him; in 1426 a sepulchral slab for the Bishop of Grosseto, in the cathedral of Siena, and in 1427 a relief for the font of the baptistery there, representing "Salome's Dance"—the first really sculptural bronze relief (Ghiberti's were pictorial) of the Renaissance. For the Siena baptistery also he modeled two dancing bronze angels, which, with two others in Berlin and Florence, are the first of the kind of the Renaissance. His association with Michelozzo ceased when the latter accompanied the banished Cosimo de' Medici to Venice in 1433.

In the same year Donatello went to Rome, at the invitation of the sculptor Simone, whom he assisted in the decorations for the coronation of the Emperor Sigismund. The works executed during his stay at Rome show a greater than usual influence of classic art upon him. Chief among them is the Ciborium in the sacristy of St. Peter, decorated with reliefs of two "Worshipping Angels," and a fine "Burial of Christ." Meanwhile, in 1434, his friend Cosimo de' Medici had returned in triumph to Florence, and Donatello returned about the same time. He was employed in decorating the court of the Medici Palace with eight medallions—copies of antique gems—which were executed by his pupils. About the same time he designed his bronze "David" for Cosimo—the first nude statue of the Renaissance—now in the Museo Nazionale. About this time also he carved the sandstone relief of the Annunciation, in the Cavalcanti Chapel, Santa Croce, Florence, in which the antique influence is very marked, and the action is wonderfully rendered.

Between 1434 and 1438 he executed the exterior pulpit of the cathedral of Prato, the reliefs of which, representing "Dancing Angels," are of a lively, decorative effect, and were designed by Donatello, although their imperfect execution points to the work of his pupils. During the same time (1433-38) he completed his reliefs for the organ gallery of the cathedral of Florence (1440), a counterpiece of the similar subject by Luca della Robbia (q.v.). It is full of energy and dramatic action, the exaggerated motion and sketchy execution being calculated for an elevated position. Ruberto Martelli was also an appreciative patron, as is evinced by a large number of Donatello's works preserved in his house. Among these was a fine coat of arms of the family, a large bronze patera, decorated with Bacchanalian scenes, now in South Kensington Museum, London, and two representations of Donatello's favorite subject, "John the Baptist"—a bust and a statue. The statue represents him as a youthful ascetic, as does also an older statue in the Museo Nazionale, but the bust, as well as a relief of John the Baptist, in the Museo, and another at Faenza, are more ideal. In his later works Donatello also represented him as the ascetic preacher of the desert in a polychrome wooden statue in the church of the Frari, Venice (1451), and in a bronze statue in the cathedral of Siena (1457).

The third period of Donatello's art (1443-66) begins with his call to Padua in 1443. His

first work there was a bronze crucifix for the high altar of the celebrated church of Sant' Antonio; in 1446 he began a whole series of bronze sculptures for a new high altar, which, long scattered through the church, were lately united in an altar. Among them are the statues of the Madonna with Saints Anthony and Francis, Daniel and Justina, Louis and Prosdociumus; and reliefs of a "Pietà," an "Entombment of Christ" (in plaster), "Miracles of St. Anthony," "Symbols of the Evangelists," and "Angels Singing and Making Music." Although designed by Donatello, these works were executed by his pupils. The "Miracles of St. Anthony," in particular, show clearness of composition and dramatic action unexcelled in his other works. In 1446 he also began a bronze equestrian statue of "Erasmo de' Narni," called "Gattamelata." Although cast in 1447 it was not erected till 1453. As the first bronze equestrian statue since antiquity, it was epoch-making in art. The rider is of dignified and noble bearing, and the heavy war horse is full of life, and no less a portrait than the rider, though the action in walking is untrue to nature. Notwithstanding the inducements offered him to remain at Padua, Donatello was unhappy away from Florence, and in 1453 he departed. After visiting Venice, Ferrara, and other North Italian cities, he returned to Florence in 1457, where he passed the rest of his life, except for a brief stay at Siena. Several important works, partly mentioned above, belong to his last period; as, e.g., the well-known "Judith and Holofernes" (Loggia dei Lanzi), the bizarre effect of which is explained by its position as a fountain, and the skeleton-like wooden "Magdalen" in the baptistery of Florence. He devoted himself chiefly to finishing his work in San Lorenzo, a foundation of the Medici. In 1428 he had executed a fine bronze sepulchral statue for Giovanni, Cosimo's father, there, and before his departure for Padua he had designed the excellent plastic decorations of the Old Sacristy. After his return he designed the sculptures of the two pulpits, which he did not live to complete. Although damaged by the additions and omissions of his pupils, the best of these reliefs still bear witness to an undiminished dramatic power and invention. He died on Dec. 13, 1466, and was buried in San Lorenzo, near his friend Cosimo de' Medici. Vasari's charming anecdotes, confirmed by what we otherwise know, picture him as a modest and lovable character, generous with money and careless of appearance.

Seldom has an artist appeared who was more revolutionary and broke more completely with the past than Donatello. His contemporaries, Ghiberti and Luca della Robbia, represent more the conservative tendencies of the age. Donatello was the great radical. They were the classicists, he the realist—a realist of the highest kind, whose works were true to nature without being slavish copies. Not that he was deficient in knowledge of the antique; he was trained, especially at Rome, in the antique and (as in the bronze "David") he deliberately adapted poses taken directly from it. But his realistic trend was too strong to be much restrained by antique models. He deliberately sacrificed beauty to character, which no one could portray better than he. His works also abound in dramatic action. He was an excellent technician and, whether working with bronze or marble, he gained the best effects that his ma-

terials would yield. He excelled in the treatment of flesh and was a consummate master in relief, ranging through its entire scope and power in the plastic effect, as was done by Ghiberti in his last period, however, his compositions became overcrowded, and the action is exaggerated. No other artist of the day understood perspective in sculpture as he did; Vasari records interesting anecdotes of the astonishment of the Florentines at the near and distant effects of his statues and reliefs. Of the large number of pupils formerly ascribed to him, Desiderio da Settignano (q.v.), Bertoldo in Florence, and Bellano in Padua are the only important ones of whom this can be certainly assumed. Nevertheless, his influence more than any other dominated the sculpture of Florence throughout the fifteenth century, until the culmination of Italian art in Michelangelo, his artistic descendant. It also was the inspiration of the sculpture of northern Italy, and even of the painting, as is seen in the case of Mantegna, the chief master of Padua, who copied statues of Donatello. Not only was he considered the greatest sculptor of his day, but modern criticism has confirmed this judgment, placing him among the greatest sculptors of all time.

Bibliography. The chief source of information for the life of Donatello is Vasari's *Vite* (ed. by Milanesi, Florence, 1878; Eng. trans., by Blashfield and Hopkins, New York, 1896), vol. i. Vasari's testimony has been much modified by recently published documentary evidence and by a sounder critique of the master's works. Among earlier biographies the best are those of Müntz (Paris, 1885) and especially, Semper (Innsbruck, 1887), probably the best authority. Others are by Schmarow (Leipzig, 1886); Cavallini (Milan, 1886), and in *Die Kunst* (Berlin, 1906); Rea (London, 1900); Pastor (Giesen, 1892); Trombetta (Rome, 1887); Angelini, Carocci, and Melani (Florence, 1887); Raymond (Paris, 1890); Meyer (Bielefeld, 1903)—the latter a popular yet very scholarly monograph (Eng. trans., London, 1904); Lord Balcarras (ib., 1903), the best English biography; Eber (Budapest, 1903); Schottmüller (Munich, 1904); Alexandre (Paris, 1905); Schubring (Stuttgart, 1907); Bertaux (Paris, 1910); Gorboff (Moscow, 1912). For certain phases of Donatello's life and art, see Gloria, *Donatello in Padova* (Padua, 1895), and Tschudi, *Donatello e la critica moderna* (Turin, 1887). The researches of Wilhelm Bode on Donatello are of fundamental importance in such works as *Die italienischen Bronzestatuetten der Renaissance* (Berlin, 1907) and *Florentiner Bildhauer der Renaissance* (Berlin, 2d ed., 1910; Eng. trans., London, 1908). An almost complete series of reproductions of Donatello's works is in Bode, *Denkmäler der Renaissance skulptur Italiens* (Munich, 1892-1905).

DONATELLO. A young Tuscan nobleman in Hawthorne's *Marble Faun*.

DONATH, dō'nāt, JULIUS (1849-). An Hungarian neurologist and psychiatrist, born at Baja, Hungary, and educated at the universities of Vienna, Innsbruck, Berlin, and Paris. He was an assistant in medical chemistry at Innsbruck (1871-74) and in chemistry at Vienna (1874-77) and a lecturer at the technical high school of Graz (1877). During the Russo-Turkish War (1877-78) he was chief physician and operator at the Turkish field hospital of

Adrianople. He was appointed lecturer on nervous diseases at the University of Budapest (1893), and (in 1902) chief physician of nervous diseases at St. Stephan-Spitals, where he also became assistant professor in 1908. Donath introduced new methods of treatment for epilepsy, progressive paralysis, and juvenile insanity. In 1890 he founded and became editor of the Hungarian medical journal *Klinikai Fuzzetek* and in 1909 also of the international quarterly *Epilepsia*. Besides numerous scientific studies in his special fields, popular-science articles, critiques, and philosophical and sociological essays appearing in the periodicals of various countries, his publications include: *Die Anfänge des menschlichen Geistes* (1898); *Bestrebung und Fortschritt in der Behandlung der Epilepsie* (1900); *Reflex und Psyche* (1910).

DONATI, dō-nā'tē, GIOVANNI BATTISTA (1826-73). An Italian astronomer, professor in the Royal Institute and director of the observatory at Florence. In his *Intorno alle strie degli spettri stellari* (1860) he discussed the desirability of a physical classification of stars. He discovered the gaseous composition of comets and also six new comets, one of which bears his name. See **DONATI'S COMET**.

DONATION (Lat. *donatio*, gift, from *donare*, to give, from *donum*, Skt. *dāna*, gift, from Lat. *dare*, Gk. *didōnai*, *didonai*, Skt. *dā*, to give). In strict legal usage, the word "donation" is confined to the transfer of personal property made without consideration; the word "gift" being at common law restricted to a particular kind of transfer of real estate—that by which there is created an estate in fee tail—an estate, i.e., which is granted to a man and the heirs of his body. In popular usage, however, the term "gift" is more commonly employed in the sense of donation, and in the United States this is its usual legal signification also. The general classification of gifts of personal property is twofold: gifts *inter vivos* (between the living), which go into effect at once and have no reference to future events; and gifts *mortis causa* (because of—i.e., in expectation of—death). This last form of gift is usually intended to avoid the necessity of making a will when circumstances render that impossible or difficult. Only personal property can pass in this way; the transfer must be made when the death of the donor appears imminent, there must be delivery of the property, and the gift takes effect only upon the death of the donor. The gift, therefore, is really a conditional one and is ipso facto revoked by the recovery of the donor, or may be recalled by him before death actually occurs. A gift *inter vivos*, on the contrary, is absolute, and not revocable. All kinds of personal property are subject to gift, including even a *chose in action*, i.e., property of which the owner has not the actual possession, but the right of possession, and which he may reduce to possession by legal action. Such a right can only be transferred by a written assignment.

A special use of the word "donation" in this country is in the expression "donation lands," which were certain lands set apart by the State of Pennsylvania after the Revolution, in the northwest part of its territory, as a gift to its citizens who had served in the Revolutionary army. See **CONVEYANCE**; **DELIVERY**; **GIFT**; **PERSONAL PROPERTY**.

The phrase *donatio propter nuptias* ('a gift on account of marriage') was used in the civil or Roman law to designate the sum paid by a husband as the offset to the wife's dowry; this was considered partly as a jointure for the wife in case of her survival, partly as security for the return of the wife's dowry to her heirs if she failed to survive her husband. See DOWER; MARRIAGE SETTLEMENT.

DONATION OF CONSTANTINE (Lat. *donatio Constantini*). A forged document of uncertain date, possibly published about 754 A.D., to be the record of a gift bestowed by the Great upon Pope Sylvester I. By it the Bishop of Rome was granted, besides certain marks and insignia of honor, such as the tiara, the lorum, and Imperial robes, the temporal sovereignty over "Rome and all the provinces, districts, and cities of Italy or of the western regions." The Donation of Constantine, though a very clumsy forgery, was regarded for a long time as genuine and was incorporated in the collections of Canon Law; but up to the eleventh century was never made use of to vindicate papal claims. The authenticity of the document was first seriously attacked by Laurentius Valla in 1440; it was defended by many partisans for over three centuries. Since then the controversy as to the date of the forgery has been active. A translation of the Donation is given in Henderson, *Select Historical Documents of the Middle Ages* (New York, 1892). Consult Scheffer-Boichorst, *Die Konstantinische Schenkung*, vols. x, xi (Vienna, 1889-90), and Doellinger, *Die Papstfabeln des Mittelalters* (2d ed., Stuttgart, 1890).

DONATION OF PEPIN. The gift of temporal sovereignty over the Exarchate of Ravenna, the Pentapolis, and the territory of Bologna and Ferrara bestowed upon the Pope by Pepin the Short, King of the Franks, in 756. In the preceding year Pope Stephen III had summoned the Frankish King to aid him against Aistulf, King of the Lombards. Pepin crossed the Alps and defeated Aistulf, but as the latter still continued hostile to the Pope, Pepin invaded Italy a second time in 756, and took from the Lombards 22 cities, the keys of which he presented to St. Peter's. In 774 Charles the Great confirmed the papacy in possession of the territories granted by Pepin and enlarged to a considerable extent the boundaries of the earlier grant. The donations of Pepin and Charles the Great laid the foundation of the temporal power of the Pope. Consult Abel, *Jahrbücher des fränkischen Reichs unter Karl dem Grossen* (Leipzig, 1883), and Schnürer, *Die Entstehung des Kirchenstaates* (Cologne, 1894). See PAPAL STATES.

DONAT'S COMET. A comet discovered by Giovanni Donati at Florence on June 2, 1858. When nearest the earth, its tail had an apparent length of 50°. . . . to the enormous linear size of . . . and was 10,000,000 miles wide. Its period was estimated at more than 2000 years. The comet was seen until March, 1859.

DONATISTS. The followers of Donatus the Great, a schismatic body of Christians in North Africa, who flourished during the fourth century. In the persecution under Diocletian (303 A.D.) the Christians had been ordered to give up their sacred books. Those who complied with this demand were called *traditores*, and the

question how to deal with them soon became a pressing one in church discipline. Should they be readmitted to church fellowship and, if so, upon what conditions? The main body of the church, led by Rome, favored a policy of mildness. But there was also a strict party, insisting that the *traditores* were unworthy, that their presence would corrupt the body ecclesiastic, and that any priestly functions which they might perform would be ipso facto null and void. For no priest could convey a grace which he himself had not, and a "holy" church must consist only of holy members. This puritan party demanded of all who would enter their fellowship that they should submit to baptism, whether they had previously received that rite or not, although to administer baptism a second time was not the practice of the Church at large.

There was also another cause at work to produce the Donatist schism, viz., the jealousy of Carthage felt by the Numidian clergy, under the lead of their primate, Secundus, Bishop of Tigris. In 311, after the death of Mensurius, Bishop of Carthage, Cæcilian was chosen as his successor. The strict party and the "confessors" opposed Cæcilian on the ground of his laxity in discipline. They also charged that a traitor had taken part in his ordination, which was thereby invalidated. The Numidian clergy, already jealous of Carthage and displeased at not having been invited to participate in Cæcilian's election, took sides with this opposition, and these combined forces proceeded to elect a rival bishop of Carthage in the person of Majorinus. On his death, two years later (313), they elected the man from whom their party name is taken, Donatus, called the Great. Thus the North African church was divided into two hostile camps.

At Constantine's command synods were held to settle the dispute (Carthage, 311; Rome, 313; Arles, 314), and each time the Donatists lost their case. But their hold upon North Africa continued strong, and at the close of the century they were more numerous there than the Catholics. Signs of internal weakness, however, were not wanting. The Donatists had been reinforced by various malcontents, especially by the fanatical Circumcelliones (q.v.), ascetics of poor morals and worse manners, and this kind of support tended to encourage outbreaks of violence. Rogatus and a few followers withdrew about 370, and the serious defection of the Maximianists came in 393. All this weakened the movement and helped prepare the way for its final collapse. The chief instrument in bringing it to an end was St. Augustine of Hippo.

Augustine worked out and applied the Catholic position, which had already been pretty clearly formulated. Against the Donatists he taught that the Church on earth is a *corpus permixtum*; the wheat and the tares must grow together until the harvest. The "holiness" of the Church consists in its possession of sacerdotal power, by which it can transmit divine grace to needy men, not in the actual holiness of all its members. At first Augustine sought to win back the schismatics by means of argument. But he later came to believe in the application of force. Accordingly he approved the Imperial policy of coercion, adopted by Honorius in 405. See AUGUSTINE, SAINT.

In 411 a synod was held in Carthage, at which the whole subject of Donatism was debated anew, 286 Catholic bishops opposing 279 Donatists. The verdict (prearranged) was on the side of

Catholicism. The Donatists were deprived of civil rights, and a little later they were debarred from holding religious meetings upon pain of death. From this time Donatism rapidly lost its power. Although adherents of the sect are to be found for two centuries longer, their number and their public influence steadily decreases. The Saracen invasion of the seventh century put an end to the power of Donatism and Catholicism alike in North Africa.

Consult: Augustine, anti-Donatist writings, in vol. iv of *The Nicene Fathers* (1st series, ed. by Schaff, Buffalo, 1886); also his 93d *Epistle*; Optatus of Mileve, *De Schismate Donatistarum* (ed. by Ziwsa in *Corp. Script. Eccles. Lat.*, xxvi, Vienna, 1893); Völter, *Der Ursprung des Donatismus* (Freiburg, 1883); Harnack, *History of Dogma* (Eng. trans., Boston, 1894-1900); Simpson, *St. Augustine and African Church Divisions* (New York, 1910).

DONATO DI BETTO BARDI, dō-nā'tō dē bēt'tō bār'dē. See DONATELLO.

DONATUS. See DONATISTS.

DONATUS, AELIUS. A well-known grammarian and commentator, who taught grammar and rhetoric at Rome about 335 A.D. and was the instructor of St. Jerome. He wrote treatises, *De Litteris, Syllabis, Pedibus et Tonis*; *De Octo Partibus Orationis*; *De Barbarismo et Solacismo*, etc., which form together a pretty complete course of Latin grammar and in the Middle Ages were the only textbooks used in the schools, so that *Donat* came, in the west of Europe, to be synonymous with grammar or with the elements of any science. *The Donat into Religion* is the title of a book by an English bishop, and there was an old French proverb, *Les diables estoient encore à leur Donat* ('The devils were still in their grammar'). The Latin grammar of Donatus has formed the groundwork of the elementary treatises on that subject to the present day. His was one of the first books in which the art of printing by means of letters cut on wooden blocks was tried, and copies of these Donatuses are reckoned among the greatest of bibliographical curiosities. The best edition of Donatus is in vol. iv of Keil's *Grammatici Latini* (Leipzig, 1864). The author also wrote a commentary on Terence, of which we possess only a part, covering five comedies, to be found in the edition of Terence by Klotz (2 vols., Leipzig, 1838) and, better still, in the edition of Wessner (3 vols., Leipzig, 1902-08); and an important commentary on the *Æneid* and *Georgics* of Vergil, which exists to-day only in numerous quotations, preserved by Servius (q.v.). For the commentary on Terence, consult Karsten, *De Commentationis Donati ad Terenti Fabulas Origine et Compositione* (Leyden, 1907).

From this Donatus we must distinguish a later grammarian, **TRIBERIUS CLAUDIUS DONATUS**, also of the fourth century A.D., author of a voluminous commentary, of little importance, on the *Æneid*. This is edited by Georgii (2 vols., Leipzig, 1905-06).

DONAÜWÖRTH, dō'nou-vért' (Ger., neck of land on the Danube). A town of Bavaria, at the confluence of the Wörnitz and the Danube, about 25 miles north-northwest of Augsburg (Map: Germany, D 4). It is built in the form of an amphitheatre around the side of a hill and has the most important monthly live-stock market in Bavaria. The chief industries are saw-milling, brewing, and making machinery. Do-

nauwörth is a river port and agricultural centre. It became a free imperial city in the fourteenth century. It was taken by Bavaria in 1607, as punishment for interference with Catholics by the Protestants, and this was one of the episodes that led up to the Thirty Years' War. Here Marlborough gained a victory over the Bavarians in 1704, and the French over the Austrians in 1805. Pop., 1890, 3733; 1900, 4400; 1910, 5500. Consult Königsdörfer, *Geschichte des Klosters zum Heiligenkreuz in Donaauörth* (Donaauörth, 1829), and Stieve, *Der Ursprung des dreizehnhundertjährigen Krieges*, vol. i, *Der Kampf um Donaauörth* (Munich, 1875).

DONAWITZ, dō'nā-vīts. A town of Styria, Austria, 2 miles north of Leoben. Its iron and smelting works and rolling mills are important, about 2000 men. There are also prospecting mines. The old pilgrims' church of Freienstein occupies an adjacent eminence. Pop., 1900, 13,093.

DON BENITO, dōn bā-nē'tō. A town in the Province of Badajoz, Spain, 57 miles east by north of the city of Badajoz, near the left bank of the Guadiana, on the Ciudad-Real-Badajoz Railway (Map: Spain, C 3). It is picturesquely situated and generally well built and possesses a fine square, the Plaza de la Constitución, with a central promenade. The town is the centre of a district noted for its melons and which produces also grain, wine, oil, and vegetables. It has manufactures of textiles, liquids, flour, and soap. Don Benito is a comparatively modern town, having been founded in 1477. Pop., 1900, 16,656; 1910, 19,212.

DON CARLOS. The title of several dramas and operas based on the life of the son of Philip II of Spain. 1. A tragedy by Otway, performed in 1676, called by Gosse the best English tragedy in rhyme. Its plot was borrowed from the historical romance by the Abbé de Saint-Réal. 2. A drama by Schiller, completed in 1787. 3. An opera by Verdi, produced in Paris, March 11, 1867.

DON CARLOS. See CARLOS.

DONCASTER, dōn'kas-tēr (*Don* + *caster*, AS. *ceaster*, from Lat. *castrum*, camp). A municipal borough and market town in the West Riding of Yorkshire, England, on the right bank of the Don, 32 miles south of York (Map: England, E 3). The country around is flat, but beautiful. Fine old elms line the broad and level road from the south. Doncaster is very clean and well built and contains a handsome church of St. George (a cruciform edifice in the Decorated style), built by Sir G. G. Scott in 1858; a fine market hall; a guildhall and corn exchange. The municipality owns its gas, water, and electricity supplies, as well as the tramways, and the race course and accompanying paddocks, where blooded stock is sold, all of which constitute an important source of revenue. Markets, slaughterhouses, a public library, and an art school are also maintained by the town. It has manufactures of iron, brass, sackings, linen, and agricultural machines. The principal locomotive and car works of the Great Northern Railway are situated here. Its corn market is one of the largest in the kingdom. Pop., 1901, 28,932; 1911, 30,520. It has long been famous for its annual races, begun as early as 1615, and held in the second week of September. On an eminence 7 miles south are the ruins of Conisborough Castle (of Scott's *Ivanhoe*), a Norman-

Saxon round tower, 37 feet in diameter and 86 feet high, with walls 15 feet thick, strengthened by square buttresses. The door is reached by an external flight of 37 steps. Doncaster was the Danum of the Romans and the Dona Ceaster of the Saxons and suffered severely during the Danish invasion. It received municipal rights towards the end of the twelfth century.

DONCELLA, or **DONZELLA**, dôn-sá'lyá or dôn-zél'la (Sp., It., girl). The name in the West Indies of several small, gaudy, and graceful fishes, as the snakelike carnivorous Ophidiidæ, of which one species (*Ophidion marginatum*), also called sand cusk, extends northward to New York; or of the labroid fishes of the genus *Platy-glossus*, especially *Platy-glossus radiatus*, also called bluefish and pudding wife.

DON CÉSAR DE BAZAN, dôn sá'zár' de bá'zân'. The title of a French comedy by Duma-noir and Dennery (1844), suggested by the humorous underplot in Hugo's *Ruy Blas*. The hero is also the subject of a comic opera by Massenet (1872).

DON COSSACKS, PROVINCE (OR TERRITORY) OF THE. A region in southern Russia, bounded by the governments of Voronezh and Saratov on the north, Saratov and Astrakhan on the east, Stavropol and Kuban on the south, the Sea of Azov and the governments of Ekaterinoslav, Kharkov, and Voronezh on the west (Map: Russia, F 5). Its area is about 63,532 square miles. The surface is generally level, the portion lying west of the Don being slightly elevated. The whole territory belongs to the basin of the Don. The soil is for a large part fertile. The Don, navigable throughout the province, is connected by a railway, 45 miles long, with the Volga. Large quantities of heavy freight move by these two streams, and considerable quantities are interchanged by rail.

Agriculture is the leading industry. Rye, wheat, oats, and barley are the chief cereals grown. The cultivation of the vine is carried on extensively, the output of wine being exported all over Russia. The raising of live stock is also an important industry, and fishing, especially for herring, gives occupation to a considerable portion of the inhabitants. The territory has some of the richest coal deposits in Russia, known as the Donetz Coal Basin. Coal has been mined in the territory since the end of the eighteenth century, and the present annual output exceeds 12,500,000 tons. Iron, lead, gypsum, and salt are also mined. The manufacturing industry is but slightly developed. Tobacco and cigarette factories, flour mills, potteries, and iron works are practically the only establishments. The government is administered by the Ministry of War and is divided for administrative purposes into nine districts. The capital is Novo-Tcherkask; the chief commercial centre is Rostov. The population was estimated in 1912 at 3,591,900, of whom Cossacks (q.v.) and other Russians composed nearly 98 per cent. Latest official estimates put the number of Kal-muck Tatars at approximately 30,000, Armenians 27,000, and Jews 16,000.

DON'DERBERG, or **DUNDERBERG** (Dutch; Thunder-Mount). The name of a mountain on the Hudson River, a short distance below West Point, the subject of a local legend.

DON'DERS, FRANZ CORNELIUS (1818-89). A Dutch physiologist and ophthalmologist, born at Tilburg, North Brabant. He was educated at the University of Utrecht, in 1842 was appointed

lecturer, and in 1847 professor at that institution. He established a modern physiological laboratory at the university and erected the *Nederlandsch Gasthuis voor Ooglijders*. His researches were chiefly devoted to the physiology of optics and were considered very valuable. The introduction of prismatic and cylindrical glasses is due to him. Among his principal publications may be mentioned: *Anomalies of Accommodation and Refraction of the Eye*, a subject to which he gave especial attention (published in English by the Sydenham Society); *Die Lehre von den Augenbewegungen* (in German, 1847); the so-called Law of Donders, *De leer der stofwisseling als bron der eigenwarme* (1845); *De harmonie van het dierlijk leven* (1847). Consult Mole-schutt, *Franciscus Cornelius Donders* (Giessen, 1888).

DONDO, dôn'dô. A town in the Portuguese colony of Angola, West Africa, on the Coanza River (Map: Congo, B 4). The town is important on account of its caravan trade and its proximity to the Loanda Railway. The surrounding country is fertile, but this entire portion of the Coanza River basin is known as the "furnace," or "hell," of Angola. Dondo is also the centre of the coffee trade. It is connected by steamers with Loanda. Pop. about 3000.

DONDÚKOV-KORSSÁKOV, dôn'du-kôv' kôr-sá'kôv', ALEXANDER MICHAILOVITCH, PRINCE (1820-93). A Russian statesman. After receiving a good education at St. Petersburg University, he entered the military service, participating in many important campaigns with considerable distinction. He quickly attained the rank of general in the Russian army and in 1878 was appointed Governor of Bulgaria. After the conclusion of the arrangement effected by the Berlin Congress, he remained in R. 1. 1. 1. whose first Parliament he opened at Tirnova in 1879. He was chosen Prince of Bulgaria, but was instructed by the Czar to refuse the dignity and to secure the election of Prince Alexander of Battenberg. From 1882 to 1890 he was commander in chief of the Russian forces in Caucasasia and administrator of the civil government in that region.

DONEAU, dâ'nô', HUGUES, Latin name DONELLUS (1527-91). A French jurist. He was born at Chalons-sur-Saône and was educated at Toulouse and Bourges. After having been for 20 years professor of Roman law at Bourges, he was compelled to flee to Geneva at the time of the massacre of St. Bartholomew's Day and subsequently became professor at Heidelberg (1573), Leyden (1579), and Altdorf (1588). The civil jurisprudence of modern times has availed itself of his systematic methods. His celebrated *Commentarii de Jure Civili* (16 vols., 6th ed., 1822-34) is a faithful compilation of the civil law and legal procedure of Rome.

DONEGAL, dôn'é-gál' (Ir. *Dun-na-n Gal*, Fort of the Stranger, in allusion to the Danish invaders). A maritime county of Ireland, in Ulster Province, bounded north and west by the Atlantic (Map: Ireland, C 2). It is the largest county in Ireland and has an area of 1870 square miles, and an extensive and much indented coast line, off which lie numerous islands. The surface is, for the most part, mountainous, moory, or boggy, interspersed with many small lakes and rivers. About 35 per cent of the land is pasture. The inhabitants are mainly engaged in agriculture, in which little progress has been made. Linen and

woolen manufactures are carried on, and the female population is largely engaged in the working of muslin. Many of the inhabitants on the coast are occupied in the fisheries, and the inland salmon fisheries are also important. Capital, Lifford. The population since 1841 shows a continual decrease (though less so than in other counties), having been at that date 296,500; 1851, 255,200; 1891, 185,635; 1901, 172,722; 1911, 168,537.

DONEGAL. A seaport in the south of Donegal County, Ireland, at the mouth of the Eske, on a shallow creek of Donegal Bay, 11 miles north-northeast of Ballyshannon (Map: Ireland, C 2). It lies in a rich alluvial tract, surrounded on three sides by hills, behind which rise lofty, picturesque mountains. Near the town are Donegal Castle, formerly belonging to the O'Donnells of Tyrconnell, and the ruins of a Franciscan monastery, founded in 1474 by the first wife of Hugh Roe, completed by his second wife, and richly endowed by the O'Donnell family, some of whom spent their last years in its cloisters. Here was written the collection of early Irish chronicles known as the *Annals of the Four Masters*, a record of Irish history to 1616, finished in 1636 by Michael O'Cleary, a Franciscan scholar, and his associates. Pop., 1901, 1214; 1911, 2647.

DONELUS. See DONEAU, HUGUES.

DON'ELSON, ANDREW JACKSON (1800-71). An American politician and diplomat. He was born near Nashville, Tenn., and was educated at Nashville College and at West Point Military Academy. Commissioned a lieutenant of engineers, he accompanied, in 1820, his uncle, Gen. Andrew Jackson, as his aid-de-camp, to Florida. In 1822 he resigned from the army, and after a year's study of law at Transylvania University at Lexington, Ky., he was admitted to the bar. He actively participated in the campaigns of Jackson for the presidency in 1824 and 1828 and after the latter's inauguration in 1829 became his private secretary at Washington, continuing to act in that capacity through his two administrations. While charged with the Republic of Texas (1844-45) by appointment of President Tyler, he arranged a new treaty of annexation, the first having been rejected by the Senate. His mission terminated successfully with the admission of Texas to the Union in 1845. In 1846 he was appointed by President Polk Minister Plenipotentiary to Prussia and in 1848 was accredited to the federal government of Germany. Returning to the United States towards the close of 1849, he took an active part in the discussion about the acquisition of territory in the Mexican War. He attended the Southern Convention at Nashville in May, 1850, where he was one of the ablest and most earnest champions of the Union. He was a strong supporter of Clay in the Compromise of 1850 and in the year following became editor of the *Washington Union*, an organ of the Democratic branch of the Democratic party, as he did. In 1853, however, he became entirely alienated from the Democratic party, and in 1856, when ex-President Millard Fillmore was nominated for President by the American party, Donelson was made the nominee for Vice President. After his defeat he retired to private life and, although always a strong Union man, took no part in the events preceding the Civil War, throughout which he lived quietly on his estates

in Tennessee. After the war he practiced law in Memphis, Tenn.

DON'ELSON, FORT. See FORT HENRY AND FORT DONELSON.

DONETZ, dô-nyët's'. A tributary of the Don rising in the Russian government of Kursk (Map: Russia, E 5). It flows through the Province of the Don Cossacks and joins the Don at Konstantinovskaya. Its total length is over 670 miles, and it is navigable during high water to Izum, in the Government of Kharkov. Its banks are thickly wooded, and there are coal deposits in its basin from which a considerable quantity of coal is mined.

DON'GAN, THOMAS, EARL OF LIMERICK (1634-1715). A Colonial governor of New York. He was born at Castletown, County Kildare, Ireland. He served in the English and French armies with the rank of colonel and in 1678 was appointed Lieutenant Governor of Tangier by Charles II. The Duke of York appointed him Governor of the Province of New York in 1682. Being a Roman Catholic he was at first looked upon with suspicion by the colonists, but he showed himself champion of their interests and managed the relations between the English, French, and Indians with great sagacity. He granted a charter to the city of New York, and another to the city of Albany, which still remains the basis of its municipal rights. In 1688, as a result of the scheme of confederation of the Northern Colonies furthered by James II, he was obliged to resign his governorship to Sir Edmund Andros whom the English King had named as the head of the government of New England and New York. He remained in America, however, until 1691, although he had to undergo some persecution at the hands of the government which had succeeded Andros as a result of the revolution of 1688. He succeeded to the title of Earl of Limerick by the death of his brother in 1698.

DON GIOVANNI, dön jô-vân'nê. The title of an opera by Mozart, produced with unexampled success at Prague in 1787. It is the composer's masterpiece. See DON JUAN.

DONGOLA, dön'gô-lâ. A province of Anglo-Egyptian Sudan, situated between lat. 18° 30' and 19° 40' N. and lying entirely within the region known as Nubia. It is a level and fertile and produces large quantities of wheat and dates for export. Its inhabitants about 50,000 in number, are a mixed race of Turkish, Arabic, and Mameluke descent and profess Islamism. Dongola, formerly a prominent province, was taken in 1812 by the Mamelukes, who had been expelled from Egypt but they were soon compelled to abandon their new place of refuge after the expedition of Ibrahim Pasha in 1821. During the Mahdist revolt the province fell into the hands of the dervishes, from whom it was regained by the Anglo-Egyptian forces under Kitchener in 1896. The present capital of the province is El-Ordeh (q.v.), or New Dongola, on the west bank of the Nile. Old Dongola, situated on the east bank of the Nile, about 75 miles above El-Ordeh, which was an important place and capital of Dongola in antiquity, is now a mere village. The province has now railway connection with Egypt, Khartum, and the Red Sea by a short line opened in 1906 from Kareima to Abu Hamed, on a railway line connecting the cities above named.

DONGOLA (from *Dongola* in Egyptian Sudan) **KID**. Sheepskin or goatskin tanned with a semibright finish and so finished as to resemble French kid. It was first put on the market in 1880 by James Kent, of Gloversville, N. Y., and created a revolution in certain branches of the leather industry.

DONIOL, dō'nyōl' (JEAN) HENRI (ANTOINE) (1818-1906). A French publicist and historian, born at Riom (Puy-de-Dôme). He studied at the University of Paris and in 1848-50 and 1871-72 was a member of the departmental administration. In 1882-95 he was director of the national printing establishment. His publications include the following scholarly works: *Histoire des classes rurales en France* (1857), partly revised in 1900 as *Serfs et vils au moyen âge*; *La révolution française et la féodalité* (1874); *Histoire de la participation de la France à l'établissement des États-Unis d'Amérique* (5 vols. and sup., 1886-1900), a valuable and monumental work, in which numerous important documents were first placed before the public, and for which he is best known, especially in America; *De 1815 à 1900* (1903); *La Fayette dans la révolution* (1904); *Thiers* (1905). Consult the "Notice" by Voisin in *Séances et travaux de l'Académie des Sciences morales et politiques* (1909).

DONIS CONDITIONALIBUS, dō'nīs kōn-dīsh'i-ō-nāl'i-būs, **STATUTE DE** (Lat., concerning conditional gifts). The usual legal title of the famous Statute of Westminster II (13 Edw. I, c. 1), passed in 1285, which created and stereotyped the form of estate which is known as a fee tail. Prior to its enactment such estates were known as conditional fees or gifts, whence the name of the statute. Thus, a gift of lands to a man and the heirs of his body was construed to be a fee simple, descendible to his heirs in general, in case he complied with the condition that he have lawful issue. He could then, by alienating the lands to a stranger in fee simple, defeat the expectations of his issue, just as a man may now, by alienation of an estate of inheritance, defeat the expectations of his heirs. By the same act the right or expectation of any remainderman to whom the estate was to go on failure of issue was also cut off. This disposition of the conditional fee contrary to the expressed intention of the one who created it (known as the *donor*) was regarded by the great landowners as a grave abuse, and it was to remedy this that the Statute *de donis* was passed. It provided that for the future the will of the donor of conditional gifts should be observed "so that they to whom the land was given under such condition shall have no power to aliene the land so given, but that it shall remain unto the issue of them to whom it was given after their death, or shall revert unto the giver or his heirs if issue fail," etc. This limitation upon the power of the donor of a conditional gift had the practical effect of restricting the descent thereof to the heirs of his body, and so created the fee-tail estate as it has come down to us. For the permanent effects of the statute, see **FEE TAIL**; **ESTATE**.

DONJON (OF. *donjon*, *dongon*, *dongeon*, Fr. *donjon*, Prov. *donjon*, *dompnhon*, from ML. *dominio*, *dungeon*, from *dominio*, Lat. *dominium*, lordship, from *dominus*, lord), or **DUNGEON**. The principal tower or keep of a castle or fortress. It was so called because from its

position it dominated or commanded the other parts of the fortress. From the circumstance that the lower or underground story of the donjon was used as a prison has come the modern meaning of the word. See **CASTLE**; **KEEP**.

A DONJON.

DONIZETTI, dō'nē-dzēt'tē, GAETANO (1797-1848). An Italian operatic composer, born at Bergamo, Nov. 29, 1797. He studied at the local conservatory under Simon Mayr, Salari, and Gonzalez, and later at Bologna. In 1819 his first opera, *Enrico di Borgogna*, won success at Venice, and he thereafter wrote about three operas a year. He mastered so perfectly the style of Rossini, then reigning supreme, as to rival the "Swan of Pesaro" himself. Then Bellini appeared and threatened to eclipse him. Donizetti took particular pains with his *Anna Bolena* (1830), which was presented at Milan on the same night as Bellini's *Sonnambula*. This marked the beginning of more serious work on his part. *L'Elisir d'Amore* (1832), a comic opera, and the tragic *Lucrezia Borgia* (1834) and *Lucia di Lammermoor* (1835) were his next particular successes. Upon the death of Bellini he remained the undisputed master of the Italian stage and was eagerly acclaimed all over Europe. He settled in Paris (1835) and began to write for the French stage. *La fille du régiment* (1840) had enormous success at the Opéra Comique; *Les martyrs* (forbidden by the censor in Italy as *Polvuto*) and *La favorita* were both given in Paris the same year, and *Don Pasquale*, a comic opera, in 1843. In 1842 *Linda di Chamounix* created a furore in Vienna, and the Emperor showered honors upon him. Amid this unexampled series of successes and honors his mind gave way, and the last four years of his life he was insane. A great festival was held in Donizetti's honor

at Bergamo on the one hundredth anniversary of his birth, and a monument was erected there in 1855. The facility of his pen was astounding; the fourth act of *La favorita* was composed in a tavern while he was waiting for a friend, and both music and libretto of *Il Campanello di Notte* were written within nine days. With this facility he combined an endless flow of melody and a genuine dramatic talent, but his workmanship was superficial and careless. In his comic operas, as, e.g., *Don Pasquale*, *La fille du régiment*, he exhibits an excellent comic vein, and the music is light and sparkling. In all he wrote about 70 operas. Consult F. Cicconetti, *Vita di G. Donizetti* (Rome, 1864), and Ferris, *Great Musical Composers* (New York, 1887).

DON JU'AN, *Sp. pron. dôn hwân* (Sp., Sir John). A legendary figure, and one of the most widely handled in all modern poetry. The ideal of the Don Juan legend is presented in the life of a profligate who gives himself up so entirely to the gratification of sense that he acknowledges no higher consideration, and proceeds to murder the man who stands between him and his wish, fancying that in so doing he has annihilated his very existence. Partly in wanton daring, partly to allay all uneasy misgiving, he then challenges that spirit in which he disbelieves to demonstrate to him its existence in the only way he holds valid, viz., through the senses. When this actually happens, when the spirit proves its existence and power, and compels him to acknowledge its supremacy and the worthlessness of a merely sensual existence, he is crushed and sinks into hell. Although the germinal idea of the Don Juan legend appears in Juan de la Cueva's *El Infamador* (1581), the legend did not assume definite form, nor did the hero become typical, until both had been treated by the master hand of Gabriel Téllez (Tirso de Molina), in *El Burlador de Sevilla y Convidado de Piedra*. In it the hero is described as a member of a celebrated Sevillian family, Tenorio, while the action of the piece turns mainly upon his betrayal of his friend, the Marqués de la Mota, and his attempt to seduce the latter's betrothed. Being opposed by her father, he kills him, forces his way into the family tomb of the murdered man, causes a feast to be prepared, and invites the statue which has been erected over his victim to be his guest. The stone guest appears at table as invited, compels Don Juan to follow him, and, the measure of his sins being full, delivers him over to hell. This drama was worked over in Italy by Ciccognini and by Giliberto, not later than 1650. It became the basis of Dorimond's *Festin de pierre* (1658), of *Le festin de pierre, ou Le fils criminel*, of De Villiers (1660), of the *Don Juan* of Molière (1665), and of still other versions by Rosimond and Thomas Corneille. In England it was utilized by Sir Aston Cokain in the *Tragedy of Ovid* (1669) and by Shadwell in *The Libertine* (1676). Tirso's play was recast, to its detriment, in the early years of the eighteenth century by Antonio de Zamora, and Goldoni used the versions of Molière and Thomas Corneille as the foundation of his *Don Giovanni Tenorio ossia Il Dissoluto*. In the seventeenth century it served repeatedly in Italy as a theme for opera, being first used by Gluck, and later handled successively by Righini, Cimarosa, Albertini, Gazzaniga, and other composers. All of these were eclipsed by Mozart's immortal

work, *Don Giovanni*. Among modern uses of the theme are: Prosper Mérimée, *Les âmes du purgatoire*; Dumas's drama, *Don Juan de Marana*; Byron, D'Aureville, Balzac, and Flaubert's posthumous fragment; also Bernard Shaw's fantastic episode in *Man and Superman*. But the most stirring and effective modern treatment of the legend was produced in its native land by José Zorilla, whose *Don Juan Tenorio: drama fantástico-religioso*, in two parts, overshadows all others and has become so popular that it is staged annually in practically every theatre in Spain for two weeks at the festivals of All Saints and All Souls (November 1 and 2). Consult: Picatoste, *Don Juan Tenorio* (Madrid, 1883); Engel, *Die Don Juan-Sage* (Dresden, 1887); A. Farinelli, *Don Giovanni, note critica* (Torino-Roma, 1896); Gendarme de Bévotte, *La Légende de Don Juan* (Paris, 1906) and *Le Festin de Pierre avant Molière* (ib., 1907); S. M. Waxman, "The Don Juan Legend in Literature," in *Journal of American Folk-Lore*, vol. xxi (New York, 1908); Victor Said Armesto, *La leyenda de Don Juan* (Madrid, 1908); Theodor Schröder, *Die dramatischen Bearbeitungen der Don Juan-Sage in Spanien, Italien und Frankreich, bis auf Molière einschliesslich* (Halle, 1912). Schröder's work contains an excellent bibliography.

DONKEY (from *dun*, with reference to its color + double diminutive *key*). The domestic ass. See ASS, and Colored Plate of HORSES.

DONNAI. See DONAI.

DONNAY, dō'nā', MAURICE CHARLES (1859-). A French dramatist, born in Paris. He made his first appearance on the stage in 1891 with *Phryné*, a Greek shadow play, followed in 1892 by an adaptation of the *Lysistrata* of Aristophanes. All his early work embodies the essence of Parisian *esprit*, but his later work is more serious in tone. His best-known plays are: *Amanants* (1895); *Douloureuse* (1897); *L'Affranchie* (1898); *Le torrent* (1898); *La bascule* (1901); *L'Autre danger* (1901); *Le retour de Jérusalem* (1903), in which he caricatures Max Nordau; *La Patronne*; *Parabole*. *Ménage de Molière* was produced in 1912. He was elected to the Academy in 1907.

DONNDORF, dōn'dōrf, KARL ADOLF (1835-). A German sculptor, born at Weimar. He studied under Rietschel in Dresden, and upon the latter's death he aided in completing the Luther Monument at Worms, after Rietschel's designs. The statues of Savonarola, Frederick the Wise, "Valdies," and "Mourning Magdeburg" are by Donndorf. His first important independent work was the equestrian statue of Grand Duke Karl August in the Fürstenplatz, Weimar (1872). Among his works are the tombs of Robert Schumann in Bonn and the Kessstner Family in Dresden; the statues of Peter Cornelius in Düsseldorf and of Bach in Eisenach; the "Angel of the Resurrection" at Castle Reineck; the James Fountain in New York City; and the busts of Bismarck and Moltke in the National Gallery, Berlin—said to be their most characteristic likenesses. His more recent achievements are the equestrian statues of William I at Saarbrück (1904) and at Heidelberg (1905), and the National Monument at Hohensyburg, Westphalia. His work is poetic and intellectual in conception, naturalistic and forceful in treatment. He was appointed professor at Stuttgart

in 1876, and in 1910 a Donndorf Museum was opened at Weimar.

DONNE, dōn, JOHN (1573-1631). An English poet and divine. He was born in London, where his father, John Donne, who was Welsh by descent, was a prosperous ironmonger. His mother was a daughter of John Heywood the epigrammatist. He was brought up a Roman Catholic. In 1584 he was admitted at Hart Hall, Oxford, but was transferred to Cambridge, and in 1592 he was entered at Lincoln's Inn. A little later he turned Protestant. In 1596 he served under Essex in the famous expedition to Cadiz, and on his return was appointed secretary to Sir Thomas Egerton, Keeper of the Great Seal. During the next few years he wrote many poems, some of which circulated in manuscripts, but none were published. In December, 1600, he secretly married Anne, then only 17 years old, the daughter of Sir George More, brother of the Lord Keeper's wife. In consequence of this act he was dismissed from office and was even committed to the Fleet, but he soon obtained his release. Though James was friendly towards him, the King gave him no post at court. Donne continued to write verse, sending the manuscripts of his *Divine Poems* to the mother of George Herbert in 1607. In 1610 he wrote for the King the *Pseudo-Martyr*, an argument against the attitude of the Catholics towards the oath of allegiance. This was his first publication. The next year he published a beautiful elegy on the death of Elizabeth, daughter of Sir Robert Drury, who was Donne's patron. This poem was followed in 1612 by a philosophical poem, called *The Progress of the Soul*. Donne soon began to look towards the Church for a career. In 1615 he was ordained in London, and the University of Cambridge made him a D.D. The next year he was presented to the livings of Keyston in Huntingdonshire and of Sevenoaks in Kent. He never resided in either parish, but he held Sevenoaks till his death. The same year he was appointed divinity reader at Lincoln's Inn, and in 1621 he was elected dean of St. Paul's. He died March 31, 1631, and was buried in St. Paul's. As a preacher, Donne at once attained eminence. His verse consists of satires, elegies, religious poems, epistles, and epigrams. Donne was among the first of a series of poets of the seventeenth century who, under the infelicitous name of "the metaphysical poets," fill a conspicuous place in English literary history. The directness of thought, the naturalness of description, the rich abundance of genuine poetical feeling and imagery, now began to give way to cold and forced conceits, and elaborate exercises of the intellect. Yet it is generally acknowledged, even in the case of Donne, that amid all this there is real poetry, and that of a high order. Especially beautiful are *The Storm*, *The Calm*, *The Blossom*, *The Primrose*, and *Upon Parting with his Mistress*. Donne's influence has been very great, for not only did he found a school of poetry which flourished till the advent of Dryden, but his intensity and obscurity passed into Browning. Donne published little, but from his voluminous manuscripts a collection of the poems was published in 1633; and 80 sermons in 1640, to which was prefixed a charming Life by Isaak Walton. For his poems, consult the editions by Grosart, in *Fuller's Worthies Library* (London, 1872); and by Chambers, with introduc-

tion by Saintsbury (ib., 1896); for sermons: Alford, *The Works of John Donne* (ib., 1839); for his life: Jessop (ib., 1897), and Gosse, *Life and Letters of John Donne* (ib., 1899); Donne's *Letters to Several Persons of Honour* (New York, 1910), edited and annotated by C. E. Merrill, Jr., throws new light on the poet. In 1912 (Oxford) appeared *Poems; With Introductions and Commentary*, edited by H. J. C. Grierson (2 vols. Vol. i contains text and appendixes; vol. ii, introduction and commentary).

DONNE CURIOSE, dōn'nā kūr'ō-sā, LÉ. An opera by Wolf-Ferrari (q.v.), first produced at Munich, Nov. 27, 1903; in the United States, Jan. 3, 1912 (New York).

DON'NELLY, IGNATIUS (1831-1901). An American journalist, politician, and essayist of eccentric ingenuity. He was born in Philadelphia, studied law there, and was admitted to the bar in 1852, went to Minnesota in 1856, and was elected Lieutenant Governor of that State in 1859 and 1861. From 1863 to 1869 he was a representative in Congress. In 1873-78 he edited at St. Louis the *Antimonopolist*, a weekly newspaper in support of the Greenback policy, and in 1876 was president of the Antimonopoly Convention that nominated Peter Cooper for the presidency of the United States. For many years he served as a Democrat in both houses of the Legislature of Minnesota. He was nominated for the vice presidency of the United States in 1898 by the People's party and in 1900 by the "Middle-of-the-Road" wing of that party. Latterly he edited at Minneapolis a journal called the *Representative*. His *Atlantis* (1882; 8th ed., 1910) endeavored to prove that the island of that name once really existed and was the original seat of civilization. *Ragnarök* (1883) undertook to explain the geologic formations of the drift age by cometary contact. *The Great Cryptogram* (1887) sought, by the application of an elaborate word cipher to the First Folio, to furnish convincing evidence of the Baconian authorship of Shakespeare. He also wrote *Cæsar's Column*, a novel (1890; 1906), and *Cipher in the Shakespeare Plays* (1900).

DONNELLY, SAMUEL BRATTON (1866-). An American public printer and union labor leader, born at Concord, Pa. He was educated at the State Normal School, Shippensburg, Pa., taught until 1886 in the schools of Franklin County, and then entered the printing trade. He was president of the New York Typographical Union No. 6 (1895-98) and of the International Typographical Union, Indianapolis (1898-1900), and served as secretary of the National Civic Federation (1901-02) and of the Joint Arbitration Board of the New York Building Trades Employers' Association (1903-08). He served as commissioner of the New York Board of Education from 1901 until 1908, when he was appointed public printer at Washington.

DON'NER, JOHANN JAKOB CHRISTIAN (1799-1875). A German translator of the classic poets. He was born at Krefeld and, after studying at Tübingen, was professor at Stuttgart from 1843 to 1852, when he resigned his professorship to devote himself entirely to literary labors. He rendered the works of the Greek and Roman poets into German in their original metres. Among his translations are those of the satires of Juvenal (1821), Persius

(1822), and the tragedies of Sophocles (1838-39; 11th ed., 1889). This work, his masterpiece, is still the basis for almost all the metrical translations of Sophocles. It was followed by translations of Euripides (1841-53), Aeschylus (1854), the *Iliad* (1855-57), the *Odyssey* (1858-59), Pindar (1860), and Aristophanes (1861). His translations of Terence (1864), Plautus (1864-65), and Quintus Smyrnaeus (1866), were less successful.

DONNER, RAPHAEL (1693-1741). An Austrian sculptor. He was born at Esslingen and studied under Giuliani in Vienna and later visited Italy. In 1725 he furnished statues for the Archbishop's palace in Salzburg, and in 1728 was appointed chief architect to the Hungarian Primate in Pressburg, where the decoration of the Eleemosynary Chapel in the cathedral is the only work of his which has survived. His masterpiece is the fountain in the Neu Markt at Vienna, the original of which was replaced by bronze copies in 1873. Other fine works are a lead relief for a fountain in the court of the Old Town Hall, Vienna, and a group of the "Crucifixion" in Gurk Cathedral. He was the most important representative of baroque sculpture in Austria, and substituted for the overelaborate and confused style of Bernini, then dominant in plastic art, a simpler method, combining the rococo and the antique.

DONNYBROOK (Ir., church of St. Broc). Now a part of the city of Dublin, Ireland. It was formerly famous for its fair, instituted under King John in 1204 and held annually in August. Originally of two weeks' duration, in later times the fair lasted only a week. It became notorious for its attendant debauchery and fighting and in 1855 was finally abolished. Consult B. Gray (pen name of R. B. Coffin), *Donnybrook Fair* (New York, 1865).

DONORA, dō-nōr'ā. A borough in Washington Co., Pa., 35 miles south of Pittsburgh, on the Pennsylvania and the Pittsburgh and Lake Erie railroads, and on the Monongahela River (Map: Pennsylvania, A 7). It is in a coal-mining and agricultural region and has manufactories of steel, wire, chemicals, fence, nails, and gas mantles. At Fells Church, 1 mile east of here, the Whisky Insurrectionists held several meetings in 1794. Donora was incorporated in 1900. Pop., 1910, 8174.

DONOSO, dō-nō'sō, Justo (1800-68). A Chilean bishop, jurisconsult, journalist, professor, and statesman, born at Santiago de Chile. He became rector of the Seminario Conciliar in that city and was subsequently appointed lecturer on theology and secretary of the theological faculty at the university, and judge of the ecclesiastical court. He was one of the founders of the *Revista Católica*, which was published for more than 30 years, and was distinguished for his versatility as a lecturer, author, and minister. He afterward became Bishop of Ancud (1844-55) and Serena (1855-68). His publication entitled *Instituciones de derecho canónico americano* (1849 and 1863) is regarded as a standard work. Of great importance, too, is his *Diccionario teológico, canónico, y litúrgico* (1855).

DONOSO-CORTÉS, dō-nō'sō kōr-tās', JUAN FRANCISCO MARÍA DE LA SALUD, MARQUÉS DE VALDEGAMAS (1809-53). A Spanish author and diplomat, born at Valle de Serena (Estremadura). He was educated in the humanities at Salamanca and for the bar at Seville,

entered public life, and took the part of Isabella against Don Carlos in the revolution of 1832. He was Secretary of the Council under Mendizabal and followed the Queen mother in her flight to France (1840). When she returned, he was made Secretary (1844), had charge of the education of the young Queen, and was finally sent as Ambassador to Berlin (1848). About this time he astonished his countrymen by proclaiming the absolute supremacy of the Catholic church in his work, *Ensayo sobre el catolicismo, el liberalismo y el socialismo* (1851). He died while Ambassador to Paris, his last official post. His works were published, with a biography by Tejado (5 vols., Madrid, 1854-55).

DON PASQUALE, pās-kwā'lā. A comic opera by Donizetti, first produced at Paris, Jan. 3, 1843; in the United States in 1849 (New York).

DON QUICHOTTE, dōn kē-shōt'. An opera by Massenet (q.v.), first produced at Monte Carlo, Feb. 19, 1910; in the United States, at New Orleans, Jan. 27, 1912.

DON QUIXOTE, dōn kwiks'ōt, *Sp. pron.* dōn kē-īō'tā. See CERVANTES.

DON SALTER'S COFFEEHOUSE. An eating house and museum, established by John Salter, a barber, in 1695, in Cheyne Walk, Chelsea, London, and demolished in 1866. It is frequently mentioned by Swift, Steele, and other writers of that period.

DON SANCHE D'ARAGON, dōn sūnsh dā-rā-gōn'. A comedy by Corneille, derived from a Spanish play, *El palacio confuso*, and produced in 1650.

DONUS, or **DOM'NUS** (?-678). Pope from 676 to 678. He was a patron of architecture and the arts, and made a rebellious archbishop of Ravenna acknowledge the claims of Rome. A Donus II is sometimes placed on the list of popes for the year 974. This is an error, the word *domnus* in the expression *domnus papa*, used as a shorter form of *dominus*, having been wrongly taken as a proper name.

DONZELLA. See DONCELLA.

DOO, GEORGE THOMAS (1800-86). An English engraver. He was born at Christchurch, Hants, and studied under Heath in London. His "Duke of York," after Sir Thomas Lawrence, engraved in 1824, was his first important work. In 1825 he went to Paris and studied under Suisse. Doo was appointed court engraver to William IV and also to Queen Victoria. In 1856 he was elected a fellow of the Royal Society and in 1857 an Academician. He devoted himself chiefly to old-style line engraving. Among the best known of his carefully executed plates are: "Nature," after Lawrence; "The Pan-hanger Madonna," after Raphael; "Ecce Homo," after Correggio; "The Pilgrims in Sight of Rome," after Eastlake; "Knox Preaching," after Wilkie; and "The Raising of Lazarus," after Sebastiano del Piombo.

D'OUGE, dō'gē, BENJAMIN LEONARD (1860-). An American classicist, brother of Martin L. D'Ouge. He was born in Grand Rapids, Mich., graduated at the University of Michigan in 1881 and studied also at the University of Bonn; was principal of the Coldwater (Mich.) high school (1881-83), taught Latin at the University of Michigan (1884-85), and in 1886 became professor of ancient languages at the Michigan State Normal College. He was presi-

dent of the Michigan Schoolmasters' Club in 1903-04 and of the Classical Association of the Middle West and South in 1910-11. He edited: *Colloquia Latina* (1888); *Viri Romæ* (1895); *Easy Latin for Sight Reading* (1897); *Cæsar's Gallic War* (1898) and *Second Year Latin* (1899), with James B. Greenough and M. Grant Daniell; *Helps to the Study of Classical Mythology* (1899); *Cicero, Select Orations* (1901); *Latin Composition* (1901); *Latin Composition for Secondary Schools* (1904); *Latin for Beginners* (1909; 2d ed., 1911).

D'OOGÉ, dō'kē, MARTIN LUTHER (1839-). An American classical scholar, born at Zonnenarie, Netherlands. He received the degrees of A.B., University of Michigan (1862); Ph.D., Leipzig (1873); LL.D., University of Michigan (1889), and was professor of Greek in the University of Michigan from 1870 to 1912. In 1878 he was ordained to the Congregational ministry. He was director of the American School of Classical Studies at Athens in 1886-87, and president of the American Philological Association in 1884. He was the editor of Demosthenes, *De Corona* (Chicago, 1888); Sophocles, *Antigone* (Boston, 1885); etc. He contributed also to various periodicals. In 1908 he published an elaborate work, *The Acropolis of Athens*.

DOOLEY, MR. See DUNNE, FINLEY PETER.

DOOLITTLE, CHARLES CAMP (1832-1903). An American soldier, born at Burlington, Vt. In 1862 he was appointed colonel of the Eighteenth Michigan Volunteers and subsequently served in the Peninsular campaign. He was in Kentucky in 1862-63 and Tennessee in 1863-64, was in command of Decatur, Ala., during the first day of the defense against Gen. J. B. Hood, led a brigade at Nashville, and in 1865 was placed in command of that city. For a time he was in 1865 a commander of the northeastern district of Louisiana. In that year he was brevetted major general.

DOOLITTLE, (CHARLES LEANDER (1843-). An American astronomer, born in Ontario, Ind. He graduated from the University of Michigan in 1874, served for a year on the U. S. Boundary Survey, and held the chair of mathematics and astronomy at Lehigh University from 1875 to 1895, when he was appointed professor of astronomy at the University of Pennsylvania and director of the Flower Astronomical Observatory. He was treasurer of the Astronomical and Astrophysical Society of America from 1899 to 1905 and after 1909, a vice president of the American Association for the Advancement of Science in 1893, and a curator of the American Philosophical Society. Besides contributions to scientific journals, his publications include: *Results of Observation with Zenith Telescope, Sayre Observatory* (1876-95); *Results of Observation with Zenith Telescope, Flower Observatory* (1894-1911); *A Treatise on Practical Astronomy, as Applied to Geodesy and Navigation* (1885; 4th ed., 1903).

DOOM, or **DUM PALM** (Ar. *daum*, dwarf palm, from *dāma*, to remain), *Hyphæne thebaica*. A species of palm, with fan-shaped leaves, remarkable for the repeated forkings of its stem, branching being unusual among palms. It is a native of Arabia, Upper Egypt, and the central parts of Africa. In some districts it is the most plentiful tree, sometimes forming forests; it also grows in the bare sands of the desert. Ropes are made of the fibre of its leaf-

stalks. Its fruit is about the size of an orange, but of a somewhat elongated, irregular shape. When the red outer skin is peeled off, a considerable thickness of a spongy dry substance is found within it, which has an insipid sweetness and a remarkable resemblance to gingerbread, so that the tree is sometimes called the gingerbread tree. This substance is used as an article of food, and an infusion of it as a beverage is cooling, gently aperient, and very salutary in fevers. The endosperm of the seed is hard and semitransparent, and is turned into beads and other little ornaments. Each fruit contains one seed.

DOOM BOOK. See DOM Boc.

DOOMSDAY BOOK. See DOMESDAY BOOK.

DOOMSTER. See DEEMSTER.

DOON, dōon. A river of Scotland, rising in the southeast of Ayrshire, in Loch Enoch, and flowing towards the northwest through Loch Doon past Dalmellington, Burns's monument, and Alloway Kirk, to the Firth of Clyde, 2 miles south of Ayr (Map: Scotland, D 4). It is 30 miles long. On leaving Loch Doon the river flows through Glen Ness, a picturesque rocky and wooded ravine. On an islet in the loch are the ruins of Doon Castle. Burns has immortalized the Doon in song.

DOOR (AS. *dor*, Goth. *daúr*, OHG. *tor*, Ger. *Thor*; connected with Lat. *foris*, Gk. *θύρα*, *thyra*, Ir., Gael. *dorus*, OChurch Slav. *dvǫr*, Lith. *duris*, Lett. *durvis*, Av. *dvara*, Skt. *dvār*, door). A contrivance for closing at will the opening which gives access to a building or room. Its usual form is that of a flat leaf or valve hung on hinges, and secured when closed by a latch, lock, bolt, or other device. It may be of wood, iron, bronze, or even stone or marble. The opening may be closed by a single "leaf," or valve, hung to one door jamb, or, if more than 4 feet wide, by two leaves meeting at the middle of the opening. Wide interior doorways, and doorways of barns and of railway cars may be closed by *sliding* doors, rolling on metal rails set on the inner or outer face of the wall, or in its central plane, in which case the doors, when open, disappear into pockets in the wall. For very wide openings between rooms, as in schools, *accordeon* doors are often used, consisting of a series of narrow valves or leaves hinged together so as to fold back and forth into a narrow space when open. *Storm* doors are removable doors, set outside of an entrance doorway, to provide protection against wind, snow, and rain. In modern buildings the necessity of storm doors is obviated either by two sets of permanent entrance doors with a lobby or vestibule between them, or by the use of Vankannel, or *revolving*, doors; these consist of four leaves at right angles to each other, revolving on a pivot in a cylindrical inclosure. *Double-swing* doors are hung on double hinges to swing either way, out or in. Doors in theatres, churches, and places of public resort are usually by law required to swing out; doors of ordinary rooms swing into the room, the doorway being rebated on that side to receive the door when closed. In rare cases doors slide vertically, being raised by counter weights to open them. *Fireproof* doors are either wholly of metal, or of wood covered with sheet iron, bright tin, or copper. Wooden doors are generally framed in panels, the vertical members of which are called stiles, the horizontal members rails; the panels being generally adorned with moldings. Large

and heavy doors are often made of vertical planks nailed on either side of a strong frame.

The earliest doors in Egypt and Chaldæa and many of those of ancient Greece and Rome were pivoted and not hinged. The famous doors of Balawat (Assyria) were of wood, adorned with bands of sheet bronze bearing reliefs of historic scenes. No Greek doors have been preserved, and of Roman doors the only extant examples are the magnificent bronze doors of the Pantheon (124 A.D.), somewhat altered in the sixteenth century. The Byzantine doors of Hagia Sophia at Constantinople are equally admirable, and Italy possesses many fine bronze doors of the eleventh and twelfth centuries, and even of earlier date (San Paolofuori, Rome; St. Angelo, Monte Gargano; Pisa; Monreale; San Zeno, Verona; and many others). These were made of thin bronze, hammered into reliefs, and applied to paneled frames of wood. With Andrea Pisano's north doors of the baptistery at Florence a new era began in Italy, of doors cast in solid bronze and then chiseled and finished by hand. The doors by Ghiberti for the baptistery (south and east doors; see Ghiberti), by Filarete for St. Peter's, and by L. della Robbia for the sacristy of the Duomo of Florence, are especially celebrated. The carved wooden doors of St. Maclou at Rouen, attributed to Jean Goujon, are fine examples of French Renaissance art, which in its later periods, from Henri IV to Louis XV, produced highly decorative types of wooden doors for mansions and public buildings. Modern bronze doors generally follow the Italian Renaissance types, e.g., those of the capitol at Washington and of St. Bartholomew's at New York. See DOORWAY.

DOORBA. See CYNODON.

DOORNBOOM, dôrn'bôm (*Acacia horrida*). One of the most common trees of the arid and steppe regions of Africa. The name "doornboom" (thorn tree), given to it by the Dutch colonists, and the botanical specific name, are due to the number and sharpness of its spines. It seldom much exceeds 30 feet in height. In house carpentry its hard, tough timber is much used. This tree yields a gum known as Cape gum, similar to gum arabic. See ACACIA.

DOORWAY (IN ART). The opening in a wall to provide access to and exit from a room or building. It may or may not be provided with a door (q.v.) or doors. The vertical sides of the opening are its *jamb*s; the beam or stone which spans the top of a square doorway is its *lintel*, whose under surface is its *soffit*. The woodwork which surrounds an interior doorway is collectively the *door casing*, and the portions of this casing which are visible on either face of the wall constitute the *trim*. It has in all ages been customary to frame or inclose the opening with some form of architectural adornment. The form of the doorway is determined by the architectural style of the building in which it is placed. In Egypt it was always rectangular, surmounted by a strongly projecting cornice. The portals between the great pylons are usually very impressive. That of the temple of Edfu is 74 feet high, with a lintel and cornice 23 feet thick. In Babylonia and Assyria the arched doorway was of brick, often decorated with faience and flanked with protecting colossi; those of the city and palace gates must have been as impressive in their way as the Egyptian. The Persians largely imitated the Egyptians in their scheme of doorways, as

is shown in the palaces of Persepolis and Susa, but surrounded them with banded architraves (q.v.). The primitive Greeks—Pelasgians, Achæans, etc.—used mainly the linteled doorway of huge, often . . . stone (e.g., Lion Gate, Mycenæ), but . . . also the forms of the true and false arch. The historic Greeks confined themselves to the rectangular doorway and evolved a type of which the most perfect example is the famous doorway of the Erechtheum. The Roman doorways were sometimes arched, but oftener rectangular, as in the Pantheon; many of them were of magnificent size and highly ornate, as at Baalbek and Palmyra. In the usual Roman type the doorway was surrounded by a banded architrave and surmounted by a rich cornice, the ends of which were sometimes supported on carved consoles or brackets. In the early Christian style doorways were of comparatively small artistic importance. Those of Byzantine buildings were, however, often of great size and splendor, as in Hagia Sophia, Constantinople, and St. Mark's, Venice.

Romanesque Doorways. The eleventh and twelfth centuries developed an entirely new type of doorway, which, originating almost simultaneously in Lombardy and France, spread through Europe. In this type the doorway was formed by a series of arches successively diminishing from the exterior face of the massive walls, the innermost and smallest arch inclosing a rectangular opening under a lintel, above which was a tympanum sculptured in relief. Nook shafts in the angles of the recessed jambs supported the successive arches, which were richly carved. In Italy elaborate canopies on columns often sheltered these doorways. In France figure sculpture was largely used in their decoration, as in the great portals of Saint-Gilles and Saint-Trophime at Arles, in Provence. The portals of Moissac, Vézelay, and Autun, in Burgundy, are hardly inferior. Such doorways were usually in a group of three, the central doorway, leading into the nave, being usually higher and broader than the lateral portals. In many cases a system of floral and geometrical ornamentation was substituted for figure sculpture, especially in England.

Gothic Doorways. About the middle of the twelfth century the French builders began to develop the pointed portals, singly or in groups of three, with severer and even more thoroughly architectural sculpture, as in the old cathedrals of Chartres, Bourges, and LeMans, and the Abbey of Saint-Denis. Out of these sprang the unrivaled Gothic doorways of cathedral architecture, of which the masterpieces in the thirteenth century are at Notre Dame (Paris), Amiens, Rheims, and Chartres. To secure sufficient depth for the increased sculptural adornments, and to allow the doorway to become itself a porch in which the worshiper might pray before entering the church, these portals were made to form gabled structures projecting beyond the face of the wall. The carved moldings of the earlier arches were replaced by concentric arched rows of arched under canopies; and life-sized or colossal figures of saints and prophets lined the deep jambs. The scholastic thought of the Middle Ages, its conceptions of the theory and history of the universe, are expressed in the sculptures of these cathedral doorways, which thus acquire an unequalled importance in the history of art. Only seldom is their importance equaled outside of France. In

Italy there are a few fine examples in the north (Verona, San Donnino) and centre (Lucca, Perugia, Orvieto), but it is in the southern region of Apulia that the most beautiful Italian examples occur, especially at Bitonto, Bitetto, Altamura, and their doorways from the thirteenth century.

Germany to some extent approached the French style. The portals of Strassburg are equal to the most brilliant French work (especially the portal of the Wise and Foolish Virgins); those of Freiberg and Nuremberg, are not much inferior, but the sculpture was usually neither as systematic nor as generally employed. Even more decidedly French imitations are found in Spain, e.g., in the portals of Burgos Cathedral. English art of the Norman and Gothic periods was far less successful; its doorways were usually insignificant, with but little sculpture and poorly composed with the façade.

Renaissance Doorways. The Renaissance returned to a more classic simplicity in doorways, in three principal types: (1) the arched doorway framed in rusticated masonry, as in the Riccardi and Pitti palaces, Florence, and Farnese at Rome; (2) the square-headed or arched doorway flanked by pilasters or columns bearing an entablature with or without a pediment; (3) the square-headed opening framed by a banded architrave carrying an entablature or pediment, often with consoles, as in the beautiful Massimi Palace doorway in Rome. In type (2) the pilasters were often carved with exquisite arabesques, and in north Italy an arched panel above the entablature often took the place of a pediment (Hall of the Two Hundred, Palazzo Vecchio, Florence; San Giobbe, Venice). The French developed monumental variations of these types in the seventeenth and eighteenth centuries. The German Renaissance doorways are low and broad, often adorned with fantastic and grotesque sculpture, as in the Fürstenhof, Wismar, and the extraordinary doorway of the Golden Hall in the castle at Bückeburg (1612); sometimes very rich (Piastenschloss at Brieg; Pfaffenstein Castle). The doorways, with and without pediments, of American Colonial houses are often of great beauty and refinement of design, especially in New England (Salem, Portsmouth, etc.). In modern work the historic styles are generally followed, as in the Romanesque portals of Trinity Church (Boston) and St. Bartholomew's (New York); but both in the United States and in Europe the individual note is often struck in designs of great beauty both of material and carving.

DOPPLER, CHRISTIAN (1803-53). An Austrian physicist and mathematician, born in Salzburg (crownland of that name). He studied at the Polytechnical Institute of Vienna and became an instructor in mathematics there. Sub-

sequently he held various academic appointments, including those of professor of elementary mathematics and practical geometry in the Technical Institute at Prague (1841-47), professor of practical geometry in the Polytechnikum of Vienna (1848-51), and director of the physical institute of Vienna University (1851-53). He is best known as the first to enunciate the well-known Doppler's principle (q.v.) in his monograph, *Ueber das farbige Licht der Doppelsterne* (1842; new ed., 1903). His further works include: *Optisches Diastemometer* (1845); *Beiträge zur Fixsternkunde* (1846); *Versuch einer systematischen Klassifikation der Farben* (1848); *Abhandlungen*, ed. by H. A. Lorentz (1907).

DOPPLER'S PRINCIPLE. A law in physics enunciated by Christian Doppler, an Austrian physicist, in 1842. If a body which is emitting waves of any kind recedes from the instrument which is receiving the waves, the wave number is apparently decreased; and conversely, if the vibrating body approaches the receiving instrument, the wave number is increased. Similar statements can be made, in general, of the effect of making the receiving instrument move away from or towards the vibrating source. This alteration in wave number is called "Doppler's Principle," having been first stated in 1842 by Prof. Christian Doppler, of Prague. If the natural velocity of waves in the medium connecting the vibrating body and the receiving instrument is V , if the velocity of approach of the vibrating body is v , and if N is the natural wave number of the waves, the new wave number will be N^1 , where

$$N^1 = N \frac{V}{V - v};$$

whereas, if v is the velocity of recession of the vibrating body,

$$N^1 = N \frac{V}{V + v}.$$

If, however, the vibrating body is not moving, but the receiving instrument is receding with a velocity v , then

$$N^1 = \frac{N}{V} (V - v);$$

and if v is the velocity of approach of the receiving instrument,

$$N^1 = \frac{N}{V} (V + v).$$

Illustrations of Doppler's principle are afforded in acoustics and in light. If a sounding body, e.g., a whistling locomotive, is approaching a listener, the pitch of the note heard is higher than when it is at rest or when receding. Similarly, if a source of light, e.g., a star or one edge of the rotating sun, is approaching an observer rapidly, the color due to any train of waves in the radiation produced in the human eye is not what would be seen if there were no relative motion in the line of sight; the color actually seen will be slightly shifted towards the blue portion of the spectrum. If a photographic plate is used to record the radiation, the actual change in wave number can be measured, and thus an idea obtained of the velocity of the source of light in the line of sight.

DOR, DORBEETLE, or DOR BUG. See CHAFER; JUNE BUG.

DO'RA. A play by Sardou, produced in 1877 and popular in an English version under the title of *Diplomacy*.

DORA, SISTER. See PATTISON, DOROTHY WYNDLOW.

DO'RAB. A fish (*Chirocentrus dorab*) of the Red Sea, Indian Ocean, and Malayan waters, allied to the herrings, but having some remarkable peculiarities of structure characterizing the separate family Chirocentridæ. "The upward direction of the cleft of the mouth, which is armed with formidable teeth, coupled with the position of the lower jaw, gives a rather peculiar expression to the head, and the eyes are remarkable for being covered with skin. . . . As this fish attains a length of more than a dozen feet, it is a sufficiently formidable monster, and when captured is said to bite viciously at any object within reach. Its flesh is of poor quality."

DO'RAD. A mailed catfish of the Amazonian genus *Doras*. See CATFISH; HASSAR.

DORA D'ISTRIA, dō'rā dē'strē-ā (1828-88). A pseudonym of Helen Ghika, Princess Koltzoff-Massalsky. She was the niece of Prince Alexander Ghika, Hospodar of Wallachia, and was born at Bucharest, Jan. 22, 1828. Thoroughly instructed in the classics under the care of Professor Pappadopoulos, she added to these, by frequent travels through Germany, France, and Italy, and extensive knowledge of modern languages and literature. At the age of 15 she commenced a translation of the *Iliad* into German and not long afterward wrote several pieces for the theatre. After her marriage with Prince Koltzoff-Massalsky she accompanied her husband to the court of St. Petersburg. Her first important work, *La vie monastique dans l'église orientale*, was published at Paris and Geneva in 1855. This was followed by two works, *Gli eroi della Rumenia* and *I Rumeni ed il papato*. Her studies in Switzerland resulted in a work entitled *La Suisse allemande*. She received an official invitation in 1865 to attend the sixth centenary festival in honor of the birthday of Dante. This event she described vividly in *Pèlerinage au tombeau de Dante*. In 1867 she went to Venice to examine the ample archives of that city; but the first thing she did was to publish *Venise* in 1867. Afterward she showed the fruits of her researches in *Les Albanais musulmans* and *Gli Albanesi nella Rumenia*; *storia dei principi Ghika nei secoli XVII, XVIII, XIX* (1873). In 1868 she gave some account of her own active life in *Di alcune opere della principessa Dora d'Istria*, a work which reappeared in 1871 under the title *Dora d'Istria e la poesia albanese*. Her work *Des femmes par une femme* (1864) was translated into Russian, Italian, and English. She died at Florence, Nov. 17, 1888.

DORALICE, dō'rā-lē'cl-ā. One of the stories in Straparola's *Nights* and an old version of *Cinderella*.

DOR'AN, JOHN (1807-78). An English miscellaneous writer, descended from an old Irish family of Drogheda. He was born in London. He acquired from his father, who had lived in France, a good knowledge of French. From 1823 to 1828 he was on the Continent as tutor to a young nobleman. He had already become a contributor to the *Literary Chronicle*. When only 17 he wrote a melodrama, which, under the title of *Justice, or the Venetian Jew*, was produced at the Surrey Theatre in 1824. Four

years later he published a selection from his contributions to the press, *Sketches and Reminiscences*, and, in 1835, *History of Reading*. In 1854 appeared *Habits of Men and Table Traits*, followed by *Lives of the Queens of the House of Hanover* (1855); *Knights and their Days* (1856); *Monarchs Retired from Business* (1857); *History of Court Fools* (1858); *New Pictures and Old Panels* (1859); *The Princes of Wales* (1860); and a *Memoir of Queen Adelaide* (1861). In 1864 he produced his most substantial work, *Their Majesties' Servants*, a history of the stage from Betterton to Kean (new ed., by Lowe, 1887); in 1868, *Saints and Sinners*; and in 1873, his most interesting work, an account of Mrs. Elizabeth Montagu and the "bluestockings" of her day, under the title of *A Lady of the Last Century*. In 1876 appeared *Mann and Manners*, based on the letters of Horace Mann to Horace Walpole, followed by *London in Jacobite Times* (1877) and *Memories of our Great Towns* (1878). After his death was published *In and About Drury Lane*. Doran was closely connected with the *Athenæum* and edited that periodical for a brief period, in 1869. At the time of his death he was editor of *Notes and Queries*.

DORAS'TUS and FAW'NIA. The chief characters in Robert Greene's romance, *Pandosto* (1588), and originally the subtitle, in later editions the main title, of the romance.

DORAT, dō'rā', CLAUDE JOSEPH (1734-80). A French poet, born in Paris. He was at first an advocate, then a mousquetaire, and finally gave himself up to authorship. His works include almost every form of verse and prose, plays, fables, madrigals, romances, and letters. The plays are decidedly mediocre. He celebrated the "little nothings" of his day in elegant but stilted and affected verse and may be summed up as a boudoir poet. His best-known romances are *Les sacrifices de l'amour, ou lettres de la vicomtesse de Senanges et du chevalier de Versenay* (1771) and *Les victimes de l'amour, ou lettres de quelques amants célèbres* (1776). Consult Desnoiresterres, *Le chevalier Dorat et les poètes légers au XVIIIe siècle*.

DORAT, JEAN. See DAURAT, JEAN.

DOR/CAS (Lat. gazelle, Gk. δορκάς, *dorkas*, from δέρεσθαι, *derkesthai*, to look, Skt. darś, to see) **GAZELLE.** One of the commonest gazelles (*Gazella dorcas*) of the hilly parts of the central Sahara desert, where in winter it gathers into large herds. It also occurs in Syria. It is about 2 feet high and fawn-colored, with the rump, abdomen, inside of the legs, and ears white; conspicuous white streaks encircle the eyes and curve down to the nostrils. Both sexes bear relatively long and slender horns. It is locally called, by the Sahara Arabs, rhezal and hemar. See GAZELLE, and Plate of GAZELLES.

DOR/CHESTER. A municipal borough and the capital of Dorsetshire, England, on the Frome, about 8 miles north of Weymouth (Map: England, D 6). The town is clean and well built and almost surrounded by avenues of beautiful trees. The church of St. Peter contains some curious monuments. Among the other notable buildings are the guildhall, county building, corn exchange, county prison, and barracks. The county museum contains an excellent collection of antiquities. The town owns its water supply, markets, and the corn exchange. Its chief industry is the brewing of

ale and beer, and the production of butter for the London market. Its markets for cattle and cereals are important. Pop., 1901, 9458; 1911, 9842. Near Dorchester are the "Maumbury Rings," the most complete remains of a Roman amphitheatre in England. Its dimensions are 220 by 165 feet, and 30 feet deep. The seats, rising from the arena cut in the chalk, are capable of holding 13,000 spectators. Poundsbury and Maiden Castle are two intrenched camps—the first perhaps of Roman origin, the second of British. Dorchester, British in origin, was the Roman Durnovaria, or Durinum, a walled town with a fosse. The walls are still partly visible. During the Civil War it was fiercely Parliamentary. At Dorchester, in September, 1685, Judge Jeffreys, in his "Bloody Assize," sentenced 292 persons to death for participation in the Monmouth Rebellion.

DORCHESTER. A port of entry, the capital of Westmoreland Co., New Brunswick, Canada (Map: New Brunswick, E 3). It is situated on the Memramcook River, 2 miles from Shepody Bay, 12 miles from Sackville, and on the Intercolonial Railway, 115 miles by rail northeast of St. John. It has a good harbor and carries on a considerable export trade in building stone from neighboring quarries, in gas coal, and in lumber. There is a worsted factory. The penitentiary of the Maritime Provinces is on a hill overlooking the town. Pop., 1911, 1080.

DORCHESTER. Formerly a town in Norfolk Co., Mass., but since 1870 a ward of the city of Boston. Dorchester was settled in June, 1630, by a company of Puritans headed by their pastors, Maverick and Warham, who came over in the *Mary and John* of Winthrop's fleet. The settlement was originally called Mattapan, but later in the year was incorporated as Dorchester, in the order by the court of assistants, at Charlestown, passed Sept. 17, and which also incorporated Boston. It was named after Dorchester, England, the home of some of the emigrants and of Rev. John White, the prime originator of the movement which resulted in the Massachusetts Bay charter. As a settlement, it antedates Charlestown and Boston, and was described in 1633 as "ye greatest towne in New England." The territory then extended nearly 35 miles, to within a few rods of the Rhode Island line. It instituted the first special town government in New England. From it in 1636 went the company under Roger Ludlow which founded Windsor, Conn.; and also, in 1695, the company which established a settlement of Dorchester in South Carolina and ultimately founded Midway, Ga. By fortifying Dorchester Heights, on March 5, 1776, Washington forced the English to evacuate Boston. The original town comprised Milton, Canton, Stoughton, Sharon, and Foxboro, besides parts of Wrentham, Dedham, the Hyde Park district of Boston, Squantum in Quincy, and South Boston. Dorchester was the birthplace and early home of Edward Everett. Consult: *History of the Town of Dorchester by a Committee of the Dorchester Antiquarian and Historical Society* (Boston, 1859); Orcutt, *Good Old Dorchester: A Narrative History of the Town, 1630-1893* (Cambridge, 1893); Everett, *Dorchester in 1630, 1776, and 1855: An Oration delivered on July 4, 1855* (Boston, 1855).

DORCHESTER, DANIEL (1827-1907). A Methodist Episcopal clergyman. He was born

in Duxbury, Mass., and was educated at Wesleyan University, Connecticut. For three terms of four years each he was a presiding elder, and in 1854 he was a member of the Connecticut State Senate. From 1881 to 1885 he was historiographer of the New England Methodist Historical Society and in 1885 was president of the National League (nonsectarian) for the Suppression of the Liquor Traffic and for some time was superintendent of Indian Schools for the United States. Among his published works are: *Concessions of "Liberalists" to Orthodoxy* (1878); *The Problem of Religious Progress* (1881); *Giving and Worship* (1882); *Latest Drink Sophistries Versus Total Abstinence* (1883); *The Liquor Problem in All Ages* (1884); *The Why of Methodism* (1887); *Christianity in the United States* (1888); *Romanism Versus the Public School System* (1888).

DORCHESTER, LORD. See CARLETON, SIR GUY.

DORDOGNE, dôr'dôny'. A river of south central France, formed by the junction of the Dor and Dogne at the foot of Mont Dore. It flows west through the departments of Corrèze, Lot, Dordogne, Gironde, and joins the Garonne 13 miles north of Bordeaux. It is about 305 miles long and navigable to Souillac, about 186 miles. Ocean steamers ascend to Libourne.

DORDOGNE. A southwestern department of France, formed of the ancient Province of Périgord, with small portions of Limousin, Angoumois, . . . (Map: France, E 3). Area, 3561 square miles. Pop., 1901, 452,951; 1911, 437,432. The surface is hilly, with occasional beautiful and fertile valleys, the borders of which are generally covered with vineyards. It has abundant mineral deposits. It raises potatoes, fruits, chestnuts, tobacco, and cattle. Capital, Périgueux (p.v.).

DORDRECHT, dôr'drêkt, or **DORT.** A town of the Netherlands, in the Province of South Holland, situated on an island in the Merwede (Meuse delta), 12 miles southeast of Rotterdam (Map: Netherlands, C 3). The town preserves a mediæval appearance. Its large Gothic Groote Kerk has some beautiful wood carving, a fine nave and tower. The Merwede forms a large, deep harbor. Its trade in wine and lumber is considerable; its products include ships, sugar, chocolate, cigars, metal wares, glass, flour, and lumber. It is a centre for the East India trade, exporting Rhine and Moselle wines, chalk, coal, dried fish, and millstones. Pop., 1900, 38,386; 1910, 47,304. Dordrecht, founded by Count Dietrich III of Holland in 1018, during the Middle Ages was the commercial centre of the country and a member of the Hanseatic League. The first assembly of the independent states of Holland was held here in 1572, and Dordrecht was the meeting place of the famous Synod of Dort (1618-19), which affirmed the doctrines of Calvin. (See DORT, SYNOD OF.) The city was formerly on the mainland, but was separated from it by the flood of 1421. Consult M. Graf, *Beiträge zur Geschichte der Stadt zu Dordrecht* (Basel, 1825).

DORE, dôr, or **MONT DORE** (often erroneously written Mont d'Or). A mountain mass in France, comprised in the great group of Auvergne (q.v.). Mountains in the Département of Puy-de-Dôme. They are of volcanic formation and rise in the Puy-de-Sancy, which is the highest peak of central France, to the height of 6190 feet.

DORÉ, dō'rā', PAUL GUSTAVE (1833-83). A French illustrator, etcher, painter, and sculptor. He was born at Strassburg. Jan. 6, 1833, the son of an engineer. His talent was very precocious. At the age of 12 he drew sketches for lithographs, and in his fifteenth year he was regularly employed as an illustrator by the *Journal pour Rire*, at the same time exhibiting series of pen sketches in the salons. He had but little education in art, and the demand for his designs was too great to allow him the requisite leisure for technical training. As a caricaturist, he was successful, but he soon turned his attention to the illustration of books. His *Rabelais Illustré*, which appeared in 1854, established his reputation, and this work was followed by an incredible number of others, equally famous. He was not only popular in France, but in the United States and throughout Europe, especially in England, where there was a Doré cult. He worked with amazing facility and fecundity, acquiring great sums of money through his art. He was made a chevalier of the Legion of Honor in 1861 and officer in 1879. He died in Paris, Jan. 23, 1883.

Doré's reputation as an artist is due to his illustrations, in which his weird and fertile imagination and his dramatic sentiment had opportunity for full sway. His drawing, however, is often faulty. He uses landscape with success, especially in order to obtain the weird and gloomy effects in which he excelled. Sometimes, as, e.g., in his last great work, *Orlando Furioso* (1880), his imagination runs riot, and his work becomes exaggerated and bizarre. His chief masterpieces of engraving, besides the *Rabelais*, mentioned above, are *Don Quixote* (1863) and Dante's *Inferno* (1861). Among the numerous other works which he illustrated were Balzac's *Contes drolatiques* (1856), *Atala* (1862), the *Bible* (1864), for which he furnished only the sketches, and La Fontaine's *Fables* (1866). He illustrated a number of important works of English literature, among which are Milton's *Paradise Lost* (1866), Tennyson's *Idylls of the King* (1867-68), Coleridge's *Ancient Mariner* (1876), and Poe's *Raven* (1883).

Doré aspired to be an historical painter and, with his accustomed facility, created many works, mostly of colossal proportions. In these his lack of technical training is particularly conspicuous, especially his faulty drawing and his lack of color sense. The English, however, made much of his painting, and there is still a permanent exhibition of his pictures in London. His first exhibited canvas was the "Battle of the Alma" (1855), and the best of his paintings are "Francesca da Rimini" and the "Neophyte" (1868). His illustrations, "Christ Leaving the Temple" and "Entry into Jerusalem," attracted much attention. Doré's landscapes and aquarelles are worse than his figure pieces. In them the artist strives after scintillating effects, but shows no real feeling for nature.

As a sculptor, his technical deficiencies are even more evident. His best-known work is the monument to Alexandre Dumas in the Place Maiesherbes, Paris. But he was more successful in a colossal vase, exhibited in the Exposition Universelle of 1878, and now in Golden Gate Park, San Francisco. The vase represents the "Vintage" and is decorated with numerous little figures of geniuses and animals, in which, in a graceful and delightful manner, the artist has expressed his exuberant fantasy.

Consult: Delorme, *Gustav Doré* (Paris, 1879); Roosevelt, *Life and Reminiscences of Gustav Doré* (London, 1885); Jerrold, *Life of Gustav Doré*; Claretie, *Peintres et sculpteurs contemporains* (2d series, Paris, 1884); Hamerton, in *Fine Arts Quarterly Review*, vol. iii (London, 1864); Beraldi, *Les graveurs du 19ième siècle* (Paris, 1885).

DORÉE. A local name in French-speaking parts of Canada for the wall-eyed pike (*Stizostedion*).

DORÉMUS, CHARLES AVERY (1851-). An American chemist, born in New York City. He graduated from the College of the City of New York in 1870 and gained his Ph.D. at Heidelberg. As assistant, and then as adjunct professor of chemistry, toxicology, and medical jurisprudence, he was a member of the faculty of Bellevue Hospital Medical College from 1874 to 1879; he held professorships in the University of Buffalo (1879-82) and in the American Veterinary College, New York (1882-92); and for 22 years taught chemistry and physics (acting professor, 1903-04) at the College of the City of New York. He obtained patents for a mechanical gas furnace and for processes for softening water, for making hydrofluoric acid, for treating kryolith, and for extracting alumina from clay. Besides numerous articles in scientific journals, his publications include *Report on Photography, Vienna Exposition* (1873) and the section "Gaseous Poisons," in the *Text-Book of Legal Medicine and Toxicology* (1903).

DOREMUS, ROBERT OGDEN (1824-1906). An American chemist, born in New York City. He graduated in 1842 at New York University, pursued studies in chemistry in Paris in 1847-48, established a chemical laboratory in New York in 1848, and graduated from the medical department of New York University in 1850. In 1861 he was appointed professor of chemistry and toxicology in the Bellevue Hospital Medical College and in 1864 professor of chemistry and physics in the College of the City of New York. He patented several chemical processes, including methods of fire extinguishing.

DOREMUS, Mrs. SARAH PLATT (HAINES) (1802-77). An American philanthropist, born in New York City. She early became interested in missionary and philanthropic enterprises and was active in organizing the Greek Relief Society in 1828, and in founding permanent homes and hospitals, particularly for women. Among these may be mentioned the Isaac T. Hopper Home for women . . . from prison, the House and School . . . for poor women, and the New York Woman's Hospital. In 1860 she established the Woman's Union Missionary Society. Her efforts in behalf of the wounded soldiers during the Civil War occupy an important place among her many noble works.

DORÉZ, LÉON (LOUIS MARIE) (1864-). A French librarian and writer on the Renaissance. He was born in Villemaur, Aube, and studied at the Ecole des Hautes Etudes, the Sorbonne, and the Ecole des Chartes. In 1890-93 he was in the French School at Rome, and then became an assistant in the Bibliothèque Nationale, where in 1905 he was made librarian of the department of manuscripts. In 1911 he received the honorary degree of LL.D. from St. Andrews University. He edited the *Revue des Bibliothèques* and the *Bibliothèque littéraire de la Renaissance*.

DORIA, dō'ri-ā, ANDREA (c.1468-1560). A

Genoese admiral. In the first half of his long career he fought in the service of various Italian princes. When Genoa was freed from French domination at the close of the reign of Louis XII, Doria, at the age of about 45 years, was appointed captain general of the galleys and cleared the northern Mediterranean of African pirates. During the first war between Francis I of France and Charles V, Doria commanded the French fleet, reinforced by his own galleys, and inflicted everywhere severe losses upon the enemy. After the defeat of Francis I near Pavia (1525) Doria accepted the command of the papal fleet, but upon the return of the King from captivity entered once more the French service, with the title of High Admiral of the Levant. He blockaded Genoa because it had espoused the cause of the Emperor, but, finding the independence of his country threatened by the French, Doria with his whole force went over to the Emperor and by so doing hastened the deliverance of Italy from French domination. In 1528 Doria entered Genoa without resistance, and, refusing the title of sovereign offered by the Emperor, established a new form of government, which remained in vigor up to the end of the republic. The grateful country decreed him the title of "Father of Peace." In 1532 Doria won a decisive victory over the Turks near Patras, and the conquest of Tunis (1535) was chiefly his work. He distinguished himself in the disastrous expedition of Charles V against Algiers in 1541. Disturbed in his last years by the conspiracy of Fiesco (q.v.), Doria took fierce revenge upon the conspirators for the death of his nephew Gianettino. He died without offspring at Genoa in the ninety-third year of his life. Consult Petit, *André Doria* (Paris, 1887), and Guerrazzi, *Vita di Andrea Doria* (Milan, 1874).

DORIAN (Gk. *Dawpeis*, *Dōrieis*, Lat. *Dores*, from Gk. *Dawpls*, *Dōris*). One of the three principal peoples of ancient Greece. According to the legend they took their name from Dorus, the son of Hellen, who settled in Doris (q.v.), which was always regarded by the Dorians as their mother country. The ancestors of the Dorians seem to have come from the north or the northwest, under the pressure of the great southward movement of the Illyrian tribes, which brought to a close the Mycenaean age in Greece. At first they probably occupied much of the later Phocis and Locris, and were only later forced back into the little mountain district of Doris. From the north coast of the Corinthian Gulf they seem to have crossed to the Peloponnesus and to have made extensive voyages from Naupactus. Dorians invaded and occupied Crete, and, though the northern coast of the Peloponnesus was not conquered, other adventurers seem to have attacked by sea Laconia, Argolis, and Corinth. Only in Laconia do the invaders seem to have kept themselves separate from the conquered tribes, and the Spartans were always regarded as the representatives of the unmixed Dorian blood. In Greek legend this conquest of Peloponnesus was connected with the mythical return of the Heracleidae, or descendants of Heracles, and placed about 1104 B.C. It is probable that the migrations did occur during the twelfth and eleventh centuries B.C., or even earlier, and from the north or the northwest. From Peloponnesus the Dorians colonized the southwest corner of Asia Minor and the neighboring islands and planted settlements in Sicily and southern Italy. In historical times the Dorians seem, in general,

characterized by a conservative and somewhat stolid character, though by no means insensible to art and poetry. Consult: K. O. Müller, *Die Dorier* (2d ed., by Schneidewin, Breslau, 1844); Busolt, *Die Lakedaemonier und ihre Bundesgenossen* (Leipzig, 1878); Beloch, "Die Dorische Wanderung," in *Rheinisches Museum*, 45 (1890); Wilamowitz, *Euripides' Herakles* (2d ed., Berlin, 1895); Meister, "Dorier und Achäer," in *Abhandlungen der königlich sächsischen Gesellschaft der Wissenschaften*, 24 (Leipzig, 1904); and the histories of Greece by Grote, Beloch, Busolt, Holm, and Ed. Meyer. For the Doric dialect, see GREEK LANGUAGE.

DORIC ORDER. The oldest and simplest of the three Greek orders and the second of the five Roman orders, as usually enumerated. See ORDERS OF ARCHITECTURE.

DORID. A sea slug. See NUDIBRANCHIATA and accompanying Colored Plate.

DORIGNY, dō're'nyē', NICOLAS (1657-1746). A French engraver and painter. He was born in Paris and was the most celebrated of a well-known family of artists. His father, MICHEL (c.1617-65), a pupil of Vouet, was a painter and line engraver who developed a peculiar technique well suited to reproduce Vouet's pathetic style. His brother LOUIS (1654-1742), a clever fresco painter and etcher, was a pupil of Lebrun and afterward went to Verona, where he lived many years. Most of his work is still in that city. During a visit to Austria he executed his best work, the frescoes in the church of Santa Maria Maggiore at Trent (since destroyed), and decorative paintings for the present Ministry of Finance in Vienna. Nicolas was a pupil of his father. He spent 28 years in Italy and after his return to France was called to England by Queen Anne to engrave Raphael's cartoons at Hampton Court (see RAPHAEL), representing scenes from the New Testament. After this commission, which required from 1711 to 1719, he returned to Paris and was made a member of the Academy (1725). He is the first of the noted Raphael engravers and reproduced many other old masters. His technique is richer and more varied than that of his father, and his art, which was influenced by Audran, marks the transition from the seventeenth to the eighteenth century. His paintings were of historical and religious subjects and are of less value.

DORION, Fr. pron. dō'rē'ōn', SIR ANTOINE AIMÉ (1818-91). A Canadian statesman and jurist. He was born at Sainte Anne de la Pérade, Province of Quebec, was educated at Nicolet College, and was admitted to the bar in 1842. He represented Montreal from 1854 to 1861 and Hochelaga from 1862 to 1867 in the Legislative Assembly of the Province of Canada, and after confederation was a member of the Dominion Parliament for Hochelaga from 1867 to 1872 and for Napierville from then until 1874. With L. J. Papineau (q.v.) he was one of the founders, and during his political career a leader, of "Le Parti Rouge," the advanced section of French-Canadian Liberals, corresponding in some degree to the "Clear Grits" of Upper Canada (Ontario). (See POLITICAL PARTIES, *Canada*.) In 1858 he was Commissioner of Crownlands and French-Canadian leader in the famous two-days-long Brown-Dorion administration. In 1859, dissatisfied with the legislative union of Upper and Lower Canada, he helped to set on foot a movement for the federation of those provinces. In

1862 he became Provincial Secretary in the Macdonald-Sicotte administration and in 1863-64 was again French-Canadian leader in the Macdonald-Dorion administration, of which John Sandfield Macdonald (q.v.) was Premier. After confederation Dorion in 1873 became Minister of Justice in the Liberal administration of Alexander Mackenzie. In 1874 he was appointed Chief Justice of the Province of Quebec, a position he adorned for 17 years.

DORIS (Lat., from Gk. *Δωρίς*). A small mountainous district of ancient Hellas, between Phocis, Ætolia, and Locris, the original home, tradition said, of the Dorians (q.v.). With its four towns, Boium, Cytinium, Erineus, and Pinus, it formed the Doric Tetrapolis, which suffered severely in the Phocian, Ætolian, and Macedonian wars. Doris was also the name of the southwestern part of Caria, together with the islands of Cos and Rhodes, where were situated Dorian colonies, which formed at one time a hexapolis. In modern Greece Doris forms an eparchy in the nomarchy of Phocis. Consult Lolling, in *Athenische Mittheilungen*, vol. ix (Athens, 1884).

DORIS. See **NUDIBRANCHIATA**.

DORISLAUS, dō'rēs-lous, ISAAC (1593-1649). A Dutch-English scholar, lawyer, and diplomatist, born at Alkmaar, North Holland. He studied at the University of Leyden, removed to England, and in 1627 was appointed to the chair of history, newly established at Cambridge by Lord Brooke, and first offered to him.

From this professorship he was compelled to withdraw for his justification of the Dutch revolt against Spain. In 1629 he became a commoner of the College of Advocates, about 1640 was appointed Judge Advocate, and in 1648 a judge of the Court of Admiralty. He assisted in the trial of Charles I, and in 1649 was sent by the Council of State of the Commonwealth to conclude a treaty between England and the Dutch Republic. He was murdered at The Hague by a party of Royalists on May 12, 1649, an attack the day before having failed.

DORKING. A market town of Surrey, England, in a picturesque valley on the Mole, 26 miles south-southwest of London, on the ancient Roman road between London and Chichester (Map: England, F 5). Its chief trade is in flour; and in lime and chalk from adjacent pits. Dorking gives its name to a five-toed breed of domestic fowl. Pop., 1901, 7670; 1911, 7850. Near the town is Deepdene, the beautiful countryseat of the Duke of Marlborough, where Disraeli conceived and wrote part of *Coningsby*.

DORKING (from *Dorking* in England). A long-established breed of domestic fowls, distinguished chiefly by the presence of a fifth toe on the hinder part of the foot below the spur. The breed is especially valuable for the table. See **FOWL**, and Colored Plate of **FOWLS**.

DORKING, BATTLE OF. The history of an imaginary invasion of England, written by Gen. George J. Chesney, in 1871, to call attention to the weakness of British defenses.

DOR/MANT (Fr., sleeping). A term in heraldry denoting an animal in a sleeping or recumbent attitude, with its head resting on its forepaws.

DORMER (OF. *dormeor*, sleeping room, from Lat. *dormitorium*, from *dormire*, to sleep; so called as being primarily a bedroom window), or **DORMER WINDOW**. A structure, usually gabled, projecting from a sloping roof to hold a ver-

tical window, for the lighting of a room or other space under the roof. The structure may extend out to the plane of the wall, and its front be of masonry resting upon the wall, as in the more monumental types; or the whole structure may be of wood or metal, set farther back and higher up on the roof slope. The dormer appears in early Gothic buildings and becomes a rich feature of late Gothic stone and timbered architecture and of the Renaissance in France and those northern countries where steep roofs abound.

DORMITORY (Fr. *dormitoire*, Lat. *dormitorium*, from *dormire*, to sleep). 1. A sleeping apartment containing several beds, especially one in a large institution, asylum, or school. The dormitories of mediæval monasteries were often of artistic interest, being large halls divided lengthwise by rows of columns. They were of two types: (a) The open hall where all slept, together or in cubicles separated merely by low wooden partitions, with hangings at the entrances; (b) a building with separate cells opening from a corridor. The first was the primitive Benedictine type and was brought back among the Cistercians by St. Bernard, but the self-indulgent Order of Cluny (tenth century) had allowed to each monk a separate cell, and this became the general custom after the fourteenth century. 2. A college building containing living rooms for students (especially in American usage).

DOR/MOUSE (from archaic *dorm*, to sleep, from Icel. *dorma*, from Lat. *dormire*, to sleep + *mouse*). A small, arboreal rodent of the Old World family Muscardinidæ. The dormice, in adaptation to a squirrel-like existence, have come to resemble those animals in miniature, but in organization are much more nearly allied to the true mice (Muridæ). There are four molar teeth on each side in each jaw, their summits marked by transverse ridges. There are no cheek pouches and no cæcum. The ears resemble those of mice. The fur is very fine and soft. The tail is long and somewhat squirrel-like. The dormice are beautiful little animals, natives chiefly of the south of Europe; but some species are also found in Asia and Africa, and the genus *Graphiurus* is entirely African. Four genera, containing about a dozen species, are included in the family. The best-known species is the red dormouse, muscardine, or hazel mouse (haselmaus) (*Muscardinus avellanarius*), an inhabitant of woods in most parts of Europe. It is about the size of a house mouse, with head proportionally large; has a rather pointed muzzle, large prominent eyes, and a flattened tail thickly clothed with rather long hair; and is of a tawny red color on the upper parts and white beneath. It is extremely gentle and easily tamed; feeds on beech mast, acorns, hazelnuts, grain, etc.; and spends the colder parts of winter in a state of torpidity, although in mild weather it wakens up to consume a little of the store of food which, like squirrels, it lays up for that season. It makes a nest of tangled or interlaced herbage, entered from above, usually in some copse or underwood, and produces about four young ones at a birth. It often assumes a remarkable posture in feeding, suspending itself by its hind feet: more generally it sits upon its haunches and holds its food in its forepaws. The fat dormouse (*Myomys*, or *Glys. glis*) is a larger species, grayish brown, about the size of a rat, with a tail very much like that of a squirrel,

and is a native of the south of Europe, where it inhabits forests, leaping from branch to branch with great agility. The garden dormouse (*Eliomys nitela*, or *Dymomys nitedula*), common in Europe as far north as Poland, is frequently found in gardens and even in outhouses. It is often very destructive of the fruit of wall and espalier trees. It is rather smaller than the fat dormouse and has the tail tufted only at the extremity. It is called *lerot* in France and *Gartenschläfer* in Germany.

DORN, ALEXANDER VON (1838-). An Austrian economist, born at Wiener-Neustadt. He became editor of the *Triester Zeitung* in 1872 and in 1884 established at Vienna the *Volkswirtschaftliche Wochenschrift*—a publication followed in 1888 by the *Exportkompass*, a commercial yearbook of the Austro-Hungarian monarchy. He was editor of the illustrated work entitled *Die Seehäfen des Weltverkehrs* (1889 et seq.) and in 1885 published the important work *Kriegsmarine und Volkswirtschaft in Oesterreich-Ungarn*. He wrote also *Amerikanisches* (1900).

DORN, EARL VAN. See VAN DORN.

DORN, JOHANN ALBRECHT BERNHARD (1805-81). A Russian Orientalist, born at Scheuerfeld, Duchy of Coburg. He studied at Halle and Leipzig and later successively became professor of Oriental languages at the University of Kharkov (1826), professor of the history and geography of Asia at the Oriental Institute, St. Petersburg (1835), director of the Asiatic Museum (1842), and chief librarian of the Imperial Public Library (1843). His works, which are devoted to the history and language of Afghanistan and Caucasus, include: *Ueber die Veranlassung des persischen, germanischen, und griechisch-lateinischen Sprachstammes* (Hamburg, 1827); *Auszüge aus muhammedanischen Schriftstellern* (St. Petersburg, 1858); *Catalogue des manuscrits et xylographes orientaux de la Bibliothèque Impériale* (1852); *Caspia: Ueber die Einfälle der alten Russen in Tabaristan* (1875); *A Chrestomathy of the Pushtû, or Afghan Language* (with a glossary, 1847); *History of the Afghans, translated from the Persian of Nî'mat Allah* (2 vols., 1829-36). The two works last-mentioned were written by the author in the English language.

DORNER, dör'nër, AUGUST JOHANNES (1846-). A German theologian and philosopher, son of Isaac August Dörner. He was born in Schiltbach, Baden, and was educated at the universities of Berlin, Göttingen, and Tübingen. In 1869 he was minister of German congregations in Lyons and Marseilles. He traveled in the Orient, became a teacher at Göttingen (1870), and after a trip to North America in 1874 became professor and director of the Wittenberg Theological Seminary. In 1890 he went to Königsberg and in 1908-09 was rector of the university. He edited his father's correspondence with Martensen (1888) and his *System der christlichen Sittenlehre* (1885); and he wrote: *Augustinus* (1873); *Kirche und Reich Gottes* (1883); *Predigten vom Reiche Gottes* (1880); *Dem Andenken von I. A. Dörner* (1885); *Das menschliche Erkennen* (1887); *Das menschliche Handeln, philosophische Ethik* (1895); *Grundriss der Dogmengeschichte* (1899); *Encyklopädie der Theologie* (1901); *Grundriss der Religionsphilosophie* (1903); *Heilsglaube und Dogma* (1905); *Die Entstehung der christlichen Dogmen* (1907); *Pessimismus, Nietzsche,*

und Naturalismus (1911); *Die Metaphysik des Christentums* (1913); and many contributions to theological journals.

DORNER, ISAAC AUGUST (1809-84). A German theologian. He was born at Neuhausen ob Eck, Württemberg, June 20, 1809, the son of a Lutheran minister. He studied at Tübingen and became a professor there in 1837, at Kiel, 1839, and in 1843 professor of divinity and counselor of the consistory at Königsberg. From 1847 to 1853 he held a chair at Bonn, then removed to Göttingen, and in 1861 was appointed professor of systematic theology and exegesis in the University of Berlin. His best-known work is the *History of the Development of the Doctrine of the Person of Christ* (1861-63). Other works, translations of which have been published, are: *History of Protestant Theology* (1871); *System of Christian Doctrine* (1880-84); *Christian Ethics* (1887). He died at Wiesbaden, July 8, 1884. He was a strong upholder of Christianity as opposed to Germanism. His eschatological views, which were not fully in accord with the prevalent theology, were separately translated by Newman Smyth, *Dörner on the Future State* (New York, 1883). Consult the important *Briefwechsel zwischen H. L. Martensen und I. A. Dörner* (Berlin, 1888). Consult also Pfeiderer, *The Development of German Theology Since Kant* (New York, 1890).

DOR/NICK, DORNIC, or DORNOCK. A species of stout linen cloth woven in a simple diaper pattern. Dornicks were formerly made in considerable quantity at Dornich, or Tournay, in the Netherlands, and hence their name. From this place the manufacture was probably carried to Norfolk, England, by the Dutch, who emigrated thither during the persecution of the Duke of Alva.

DORNOCH, dör'nòc. A royal burgh and the capital of the County of Sutherland, Scotland, situated on the north shore, near the entrance to the Dornoch Firth—an inlet of the North Sea, running 25 miles inland, and separating Sutherlandshire from Ross and Cromarty (Map: Scotland, D 2). The cathedral, built about 1245 by Bishop Gilbert Murray, was partially burned in 1570, but was restored in 1837 and is now used as the parish church. Dornoch was in olden times the residence of the bishops of Sutherland and Caithness. The castle, which was the bishop's palace, was destroyed in 1570, and only its west tower remains. The town is a favorite summer resort on account of its excellent golf links and sea bathing. Skibo Castle, 4 miles west of Dornoch, was bought in 1898 by Andrew Carnegie. Pop. (of municipal burgh), 1901, 624; 1911, 741.

DORNROSCHEN, dörn'rës-ken. The German equivalent for 'The Sleeping Beauty.'

DOROHOL, dör'ò-hò'è. A town of northern Rumania, situated near the Austrian frontier (Map: Turkey in Europe, F 1). It is connected by rail with Jassy and has a population of (1899) 12,701, of whom nearly 7,000 are Jews. A lively trade in timber is carried on in the town. An annual fair is held on the 12th of June.

DOR'OTHE'A. 1. An unfortunate lady, whose story is told in Cervantes' *Don Quixote*. 2. The heroine of Goethe's idyllic poem "Her-mann and Dorothea." 3. The courageous Scottish Queen in Greene's *James the Fourth*, who

sacrifices herself for the good of her country. 4. The overserious Miss Brooke in George Eliot's *Middlemarch*.

DOROW, dō'rō, WILHELM (1790-1846). A German archæologist, born in Königsberg. He held various diplomatic positions from 1812 to 1827. In the latter year he visited Italy, where he began an important series of excavations which resulted in numerous discoveries and the valuable collection of Etruscan antiquities now owned by the Berlin Museum. He published: *Opferstätten und Grabhügel der Germanen und Römer am Rhein* (2 vols., 1819-21); *Etrurien und der Orient* (1829); *Voyage archéologique dans l'ancienne Etrurie* (1829).

DOROZSMA, dō'rōzh-mō. A market town of Hungary, in the County of Csongrad, about 10 miles west-northwest of Szegedin. It is in the midst of a fertile country, the inhabitants of which are largely engaged in cattle raising. There are several salt lakes near by. The town was almost wiped out by an inundation of the Theiss in 1879. Pop., 1900, 15,014; 1910, 17,719.

DORPAT, formerly also written **DÖRPT** (Russian official name *Yuriev*, Esth. *Tartolin*, Lett. *Tehrpatā*). A town in the Russian Government of Livonia, on the Embach, 163 miles southwest of St. Petersburg (Map: Russia, C 3). The fame of the town is due to its university. The Domberg, situated at the northwest extremity of the town, was formerly occupied by a citadel, a cathedral, and a bishop's palace; it now is the site of an observatory, a library, and a number of buildings connected with the university. Dorpat has a number of Protestant churches, a town hall, a monument to Barclay de Tolly, a native of Dorpat, fine promenades, and a botanical garden. It is protected by dikes from the overflowing of the Embach. Besides the famous university there is a teachers' seminary, a veterinary school, several gymnasias, and a number of scientific societies. In industrial importance Dorpat occupies in Livonia a position next to Riga. Its situation at the meeting point of the Riga, Peman, Revel Narva, and Pskov roads confer on it trade advantages which have benefited its inhabitants. There are a number of manufacturing establishments. The population (42,421 in 1897) was 44,140 in 1911, consisting principally of Estonians and Germans, including also some Russians and Jews. The official language is Russian, but German is spoken by a large proportion of the inhabitants. Dorpat is believed to have been founded by Prince Yaroslav I in 1030. With its capture by the Teutonic Knights in 1225 the town became the seat of a bishop and subsequently a commercial centre and a member of the Hanseatic League. In 1559 it was captured by the Russians, who in 1582 ceded it to Poland. It was subsequently taken by the Swedes, the Poles, and the Russians. In 1704 it came into the permanent possession of Russia. In 1708 the Russians nearly destroyed the town and removed the inhabitants to the interior of Russia. Consult Hausmann, *Aus der Geschichte der Stadt Dorpat* (Dorpat, 1872).

DORPAT UNIVERSITY. See YURIEV UNIVERSITY.

DÖRPFELD, dērp'fēlt, WILHELM (1853-). A German archæologist. He was born at Barmen and was educated at the Bauakademie, Berlin. From 1877 to 1881 he took part in

the excavations at Olympia (q.v.), becoming director of the technical operations there in 1878. In 1887 he was appointed secretary of the German Archæological Institute at Athens, with which institution he had for several years been associated as architect. He conducted excavations in many parts of the ancient Greek world, notably in connection with the study of the ancient Greek theatre; the results of these were set forth in Dürrfeld-Reisch, *Das griechische Theater* (Athens, 1906). This book was elaborately examined by Goodell, in *American Journal of Philology*, vol. xviii (1897). He occasionally cooperated with Schliemann (q.v.), and completed his excavations at Troy. He was collaborator with Curtius and others on the work entitled *Ausgrabungen zu Olympia* (1877-81) and assisted Schliemann in the preparation of the publications *Troja* (1884) and *Turyns* (1886). He wrote *Troja und Ilion* (2 vols., 1902), and published many articles in archæological journals, on the results of excavations, conducted by himself or others, in widely separated parts of the Greek world.

DORR, JULIA CAROLINE (RIPLEY) (1825-1913). An American author. She was born at Charleston, S. C., but early removed to New York and then to Rutland, Vt., where she married Hon. Seneca R. Dorr. She wrote much from her earliest years, but published nothing till 1848, when her verse and prose began to take a prominent place in American literature. Among her books are: *Isabel Leslie* (1854); *Farmingdale* (1854); *Lanmere* (1856); *Sybil Huntingdon* (1869); *Expiation* (1872); *Bermuda* (1884); *The Flower of England's Face* (1895); *A Cathedral Pilgrimage* (1896); *In King's Houses* (1898). She is best known, however, for volumes of thoughtful, artistic verse: *Poems* (1871); *Friar Anselm and Other Poems* (1879); *Daybreak: An Easter Poem* (1872); *Afternoon Songs* (1885); *Afterglow* (1900); *Beyond the Sunset* (1909); *Last Poems* (1913). A collected edition of her poems appeared in 1892.

DORR, RHETA CHILDE. An American author and social worker, born in Omaha, Neb. After studying for two years at the University of Nebraska she became editor of the woman's department of the *New York Evening Post* (1902-06), and a member of the staff of *Hampton's Magazine* (1908-11). She made special investigations as a worker in factories, mills, and department stores in order to study the labor conditions for women and children. Besides magazine articles, she is author of *What Eight Million Women Want* (1910).

DORR, THOMAS WILSON (1805-54). An American politician, famous as the leader of "Dorr's Rebellion" in Rhode Island. He was born in Providence, R. I., graduated at Harvard in 1823, studied law and was admitted to the bar, was a member of the State Assembly from 1833 to 1837 and became identified with the movement for an extension of the right of suffrage in the State. By an Act of 1798 the suffrage had been granted only to those who had a freehold valued at \$134 or bringing an annual rental of \$7. The apportionment of representatives, moreover, was unfairly made, Providence and Portsmouth, e.g., having the same number, though in 1840 the population of the former was 20 times as great as that of the latter. A suffrage party organized (1840) to effect the needed reforms called a constitutional convention, which met in October and framed a consti-

tution which in December was accepted by a large majority of the people. A constitutional convention called by the Legislature adopted a constitution (in February, 1842) which was rejected at the polls. In April the "Suffragists" elected Dorr Governor, while the opposing party, or "Landholders," chose Samuel W. King; both were formally inaugurated. In answer to a "Suffragist" attempt to seize the arsenal at Providence, Governor King, on May 18, proclaimed martial law. Dorr made an effort to secure the support of the Federal authorities at Washington, but failed, and returned to Rhode Island, where his support soon collapsed. He fled to Connecticut, but upon his return was arrested, convicted of high treason, and, in June, 1844, sentenced to imprisonment for life. In 1845, however, he was released. Though the methods of Dorr were revolutionary and unwise, they served to attract general attention to the archaic and inequitable provisions of the State constitution and led to the adoption in November, 1842, of the present constitution. By its provisions, and by amendments passed in 1886, 1888, and 1893, the suffrage has at last been made virtually universal. Consult King, *The Life and Times of Thomas W. Dorr* (Boston, 1859), and Mowry, *The Dorr War* (Providence, 1901).

DORRANCETON. A borough in Luzerne Co., Pa., opposite Wilkes-Barre, on the Susquehanna River, and on the Delaware, Lackawanna, and Western Railroad. It is purely residential and contains a hospital. Pop., 1900, 2211; 1910, 4046.

DORRIFORTH. A character in Mrs. Inchbold's *Simple Story*.

DORRIT, AMY. The unselfish heroine of Dickens's novel, *Little Dorrit*.

DORR'S REBELLION. See DORR, THOMAS WILSON.

D'ORSAY, dôr'sá', ALFRED GUILLAUME GABRIEL, COUNT (1801-1852). A French gentleman, famous chiefly as a leader of society in London and Paris. Through a morganatic marriage he was a grandson of the King of Württemberg and his family known for its devotion to the Bonapartes. In December, 1827, he married Lady Harriet Gardiner, then 15 years of age, the daughter of the English Earl of Blessington. The union was not happy and was dissolved soon after Blessington's death, in 1829. From that time until his death D'Orsay lived near the Countess of Blessington and made her residence at Gore House the centre of the fashionable, artistic, and literary society of London. In 1849 the change of government brought about their return to Paris, where D'Orsay painted a portrait of ex-King Jerome, executed busts of Lamartine and Prince Napoleon, and just before his death was appointed director of fine arts. He was tall and well built, was strikingly handsome, and was an excellent conversationalist, and for many years was regarded as an *arbitre elegantiarum* and the beau ideal of the fashionable gentleman. An accurate description of him is given by Disraeli in his novel *Henrietta Temple*, where D'Orsay appears as "Count Mirabel." Consult Richard Madden, *Life of Lady Blessington* (London, 1855).

DORSE (Ger. *Dorsch*, haddock, Dan. *torsk*, Eng. also *torsk*, tusk). The Baltic cod (*Gadus callarias*), a variety of the common cod, found in the Baltic and the neighboring seas.

DORSET or **DORSETSHIRE** (from AS.

Dorsæte, from *dor*, water, from OWelsh *dubr*, Welsh, *dufr*, Corn. *dofer*, *dour*, Ir. *dobar*, Gall. *dubron*, water + AS. *sæte*, settlers + *scire*, *scyre*, shire). A maritime county in the south of England, on the English Channel, between Devonshire and Hampshire (Map: England, D 6). It is an agricultural and stock-raising county, with an area of 987.9 square miles. Pop., 1901, 202,063; 1911, 223,274. On the east shore is Poole Harbor, a deep, lakelike inlet, south of which are the Isle of Purbeck and, to the west, St. Albans Head, Weymouth Bay, and Portland Roads. Along this coast are Lyme Regis, Charmouth, Bridport, Weymouth, Lulworth, and Swanage, all attractive watering places. Inland the surface is mostly irregular, the ranges in the southeast occasionally reaching an altitude of nearly 1000 feet. The principal rivers are the Stour, the Cale, the Lidden, the Frome, the Yeo, and the Char. The county contains a number of valuable prehistoric ruins, the most noted of which is Maiden Castle, near Dorchester, which was probably erected many years before the Roman invasion. Many interesting relics of the Roman occupation have also been discovered. Capital, Dorchester (q.v.).

DORSET, EARL OF. See SACKVILLE.

DORSEY, GEORGE AMOS (1868-). An American anthropologist, born at Hebron, Ohio. He graduated from Denison University in 1888, studied at Harvard, made anthropological investigations in South America, and was superintendent of archaeology in the department of anthropology at the Chicago Exposition (1892-93). After two years of teaching at Harvard he became assistant curator of anthropology (1896) at the Field Museum of Natural History, Chicago, and curator (1898). He also served as professor of comparative anatomy in the dental school of Northwestern University, as assistant professor of anthropology and associate professor (after 1908) at the University of Chicago, and as a member of the editorial staff of the *Chicago Tribune*. For the Field Museum he traveled through Europe, Africa, Asia, and Australasia in 1908. Dorsey was president of the American Folklore Society in 1903. He is author of more than 70 papers on anthropology and anatomy.

DORSEY, JAMES OWEN (1848-95). A distinguished American anthropologist, born in Baltimore, Md. After a course at the Theological Seminary of Virginia he was ordained a deacon in the Protestant Episcopal church in 1871 and assigned to missionary work among the Ponca and Omaha Indians of South Dakota and Nebraska. Through his linguistic and sociologic studies among these tribes he was led to form a connection with the Bureau of American Ethnology, of which he continued an active and useful member until his death, devoting special attention to the Siouan tribes. His most important work is that upon the Dhegiha language, published under the auspices of the bureau, besides which he is the author of numerous contributions in bureau reports and other scientific publications.

DORSEY, STEPHEN WALLACE (1842-). An American politician. He was born in Benson, Vt., and removed in early life to Oberlin, Ohio. He served in the Union army during the Civil War, becoming colonel of volunteers. Elected president of the Arkansas Central Railway in 1869, he removed to Arkansas, where he became prominent in reconstruction politics and

was chosen chairman of the Republican State Committee. In 1873-79 he was United States Senator, being chosen by the almost unanimous vote of both the Democratic and Republican members of the State Legislature. He was a member of the Republican National Committee in 1872, 1876, and 1880, in the last year being secretary. He was implicated in the "Star Route" frauds and indicted but escaped conviction. After 1880 he retired from politics.

DORSIVENTRALITY (from Lat. *dorsum*, back + *venter*, belly). In plants, a term of symmetry, indicating that a structure has two dissimilar (dorsal and ventral) faces, which are differently related to the environment. For example, the thallus body of an ordinary liverwort, like *Marchantia*, is dorsiventral. It is prostrate, so that one surface (the dorsal) is exposed to the air and sunlight, and the other (the ventral) is in contact with the earth or other substance on which the plant grows. As a consequence of these different exposures, the two surfaces are not only unlike in appearance, but they give rise to different organs. In *Marchantia*, e.g., the dorsal tissues, being exposed to light, develop chlorophyll, and the dorsal surface, being free, gives rise to the reproductive structures; while the ventral surface puts out rhizoids (simple rootlike structures) which penetrate the substratum and act as holdfasts. Ordinary horizontal leaves are illustrations of dorsiventral organs, the two surfaces usually differing in appearance, and the dorsal and ventral tissues differing even more decidedly in their arrangement. For example, the dorsal (upper) epidermis of such a leaf is often made up of compact cells without stomata ("breathing pores"), and is covered by a well-developed cuticle; while the ventral (lower) surface contains multitudes of stomata and may be hairy. In such a leaf the dorsal working cells (mesophyll) are closely packed together to form a dense tissue, while the cells of the ventral mesophyll are loosely aggregated. These differences in structure are due to the character of the exposure, as is evidenced by the fact that if a very young dorsiventral leaf is fixed in an inverted position, the normally dorsal region will develop the ventral arrangement of tissues and vice versa. Many underground stems, such as those of the common ferns and the ordinary rootstocks of seed plants, are dorsiventral, giving rise to roots beneath and leaves or branches above. As contrasted with a dorsiventral structure, the "radial structure" is one in which all sides are exposed alike, and such organs as are produced are repeated uniformly about the centre, as in an ordinary upright stem with its radially arranged leaves. See LEAF.

DORSTENIA. See CONTRAYERVA.

DORT. See DORDRECHT.

DORT, SYNOD OF: The largest and most important legislative council ever held by the Reformed churches, the confessional outcome of which, the "Canons of the Synod of Dort," have binding doctrinal force upon the Reformed Dutch churches. It was convened on Nov. 13, 1618, dissolved May 9, 1619, and held 154 formal sessions. Its expenses, amounting to over 100,000 guilders, were borne by the States-General of Holland, which convened it and invited all branches of the Reformed church to participate. It consisted of 84 clerical and 18 secular delegates. Of these, 58 were Dutch, England sent 8, the Palatinate and Hesse 7, Switzerland 7,

Bremen, 3 delegates. Those appointed by Brandenburg were excused on account of age; those by the National Synod of France were forbidden by the King to leave the country. The ostensible object of the gathering was to compose doctrinal differences in the church; its practical outcome was the condemnation of Arminianism as represented by the Remonstrants, defended by Barneveldt, Grotius, and most eloquently by Simon Episcopius; but opposed by the government, headed by the Stadtholder, Prince Maurice of Nassau. The entire Dutch delegation were orthodox; Utrecht alone sent Arminian delegates, and they were not allowed to sit. The synod listened to the arguments of the Remonstrants, but was uninfluenced by them. On May 8, 1619, it was voted, Hesse and England alone dissenting, that the Arminians should be excluded by the synods and classes from their ecclesiastical places. This drastic order was subsequently ruthlessly executed. The canons adopted are rigorously Calvinistic and cover the famous five points: (1) Divine Predestination; (2) Death of Christ [limited atonement]; (3) Corruption of Man; (4) Irresistible Grace; (5) Perseverance of the Saints. The Belgic Confession and the Heidelberg Catechism were also adopted, and a revision of the Dutch Bible from the Hebrew and Greek was ordered. The closing of the Synod of Dort was followed within a few days by the execution of Barneveldt, the political leader of the Arminians and the victim of the jealousy and hatred of Maurice of Nassau. Consult Schaff, *Creeds of Christendom*, vol. i, and for text, id., vol. iii (New York, 1884), and Curtis, *History of Creeds and Confessions of Faith* (Edinburgh, 1911). See ARMINIUS; EPISCOPIUS; GOMARUS.

DORTMUND, dôrt'munt. The largest city of the Prussian Province of Westphalia, and a notable mining centre, situated near the Emscher, about 73 miles northeast of Cologne (Map: Prussia, B 3). The Dortmund and Ems Canal connects the city with the Dollart at Emden, 150 miles away. The city was formerly surrounded by a massive wall, which has been removed, and the site is now marked by handsome promenades. Four of its churches are worthy of notice: the church of St. Reinoldi, of the thirteenth century; St. Mary's, built about 1150, in the Romanesque style; St. Peter's, completely restored; and the Roman Catholic parish church. The weather-beaten Rathaus, dating from the thirteenth century, restored in 1899, is still extant. Its institutions embrace two municipal gymnasia, an industrial school, numerous elementary schools, and a municipal theatre. Dortmund is in the most fertile part of Westphalia and is an important railway centre. Situated in the midst of a coal-mining district, its iron industry has grown rapidly. One large corporation, the Harpen Mining Company, employs 26,000 men; the Dortmund Union Iron Works, 12,000; the Hüsche Iron and Steel Works, 9800. It manufactures locomotives, cars, and various kinds of heavy machinery. There are flour and saw mills and numerous breweries; the zinc industry is also important. Pop., 1900, 142,418; 1910, 214,226. It is first mentioned in 899, became eventually a free Imperial city, and finally joined the Hanseatic League. It began to decline in the fifteenth century and especially from the time of the Thirty Years' War, but has grown phenomenally since the Franco-Prussian War. Consult: Thiersch, *Geschichte der*

freireichstadt Dortmund (Dortmund, 1854); Rübél, *Dortmunder finanz und steuerwesen* (ib., 1892); Sievers, *Übersichtskarte der Berg- und Huttenwerke im Oberbergamtsbezirk Dortmund* (Leipzig, 1890); A. Shadwell, *Industrial Efficiency* (London, 1906).

DOR'Y, or **DORE**, dō-rā' (Fr. *dorée*, gilded Lat. *deaurare*, to gild, from *de*, down + *aurum*, gold). 1. A local name about the upper Great Lakes for the wall-eyed pike. (See **PIKE** **PERCH.**) 2. See **JOHN DORY**.

DORYPHORUS, dō-rif'ō-rūs. See **ATHLETE**, **THE**.

DOSITHEANS. The followers of Dositheus, a Samaritan, contemporary with Jesus and the Apostles. According to Origen, he claimed to be the prophet mentioned in Deut. xviii. 18 and insisted on a curiously strict observance of the Sabbath. It is said that he starved to death in a cave. The early Christian writers often confused Dositheus with John the Baptist or with Simon Magus. There were Dositheans in Egypt as late as the sixth century, but the sect never attained great importance.

DOSITHEUS, dō-sē'tē-ūs, from Gk. Δωσιθεός), called **MAGISTER**. A Greek grammarian and instructor of Roman students, belonging to the fourth century of the Christian era. He compiled a *Latin Grammar*, using the authorities employed by Charisius and Diomedes, and translated part of this into Greek. For his *Latin Grammar*, see Keil, *Grammatici Latini*, vol. vii (Leipzig, 1871). A work styled *Ἐμπνεύματα* ('Commentaries') was long erroneously attributed to him, because in some manuscripts it appeared in connection with his *Latin grammar*. Consult Krumbacher, *De Codicibus Quibus Interpretamenta Pseudo-dositheana Nobis Tradita Sunt* (Munich, 1883).

DOSO DOSSI, dōs'sō dōs'sē, GIOVANNI DI LUTERO (1474-1542). A celebrated Italian painter of the Renaissance, head of the Ferrarese school. He was assisted in many of his works by his brother **BATTISTA** (?-1548), whose work is difficult to distinguish from his. According to traditional authorities, on whose side is Berenson, they studied under Lorenzo Costa, but later critics usually name Panetti as their master. In their youth they are presumed to have visited Rome and Venice; for Giovanni shows the influence of the Venetian colorists, and Battista—the inferior of the two—that of Raphael. About 1512 the Dossi were working for the Gonzagas at Modena, and after 1514 they were employed by the dukes of Ferrara, where they decorated palaces, churches, and villas, designed cartoons for tapestries, and designed for porcelains. In 1531 they painted the frescoes in the Castello del Buon Consiglio in Trent. Aside from these facts little is known of the life of either. The poet Ariosto mentions them in *Orlando Furioso* with the highest praise. It now seems certain that many paintings hitherto attributed to Garofalo, Giorgione, and others are Giovanni's. As a colorist he ranks first among the Ferrarese painters, and his portraits may often be compared with Titian's. His subject pictures are also of great interest, for Dosso, along with a rich and glowing color, had a whimsical originality. The artificially pastoral spirit, of which the Italy of his day was full, appealed strongly to him, and the fantastic chivalry of the poetry of his friend Ariosto touched his imagination. One of his best pictures is "Circe in the Woods," in the Borghese

Gallery, a work full of romance and mystery; a second "Circe" is in the Benson collection, London. Other notable pictures by him are: "Madonna with St. Michael and St. George," in the Modena Gallery; "Holy Night," the portrait of Ercole D'Este, and five other pictures; "St. Sebastian," in the Brera at Milan; and a number of works in the Dresden Gallery, which has more of the Dossi pictures than any other European museum outside of Italy. "St. Hieronymus," in the Vienna Gallery, and the "Rest during the Flight into Egypt" (Palazzo Pitti), are among the works attributed to Battista alone. The landscapes in their pictures are often of great beauty and had much influence on the development of independent landscape painting, of which the brothers are said to have furnished an early example in the frescoes of the Villa Imperiale in Pesaro. Consult: Morelli, *Critical Studies of Italian Painters*, trans. by Ffoulkes, vol. ii (London, 1893); Zwanziger, *Dosso Dossi* (Leipzig, 1911); Mendelssohn, *Das Werck der Dossi* (Munich, 1913).

DOST MOHAMMED KHAN, dōst mō-hām'mēd kân (1793-1863). Ameer of Afghanistan from 1826 to 1863 and founder of the Barakzai dynasty. He was a son of Poyndah Khan, an able man, prominent in the civil and military life of Afghanistan. To avenge the assassination of his father, Futteh Khan, at the behest of the Ameer Mahmud, Dost Mohammed and two of his brothers headed a rebellion, confined Mahmud to the Province of Herat, and divided the remainder of the country. Discord arose between the brothers, and Dost Mohammed, in 1826, made himself master of the country. Meanwhile Runjeet Singh, the Sikh Rajah, had occupied Peshawar, and Shah Sujah, who had been driven from the throne in 1809, had sought English aid to restore him to power. Dost Mohammed attempted to win the friendship of the Anglo-Indian government; but that body rejected his advances and entered upon a costly course of blundering in regard to Afghan affairs. Captain Burnes was sent to Kabul in 1837, where the Ameer acknowledged frankly that, despairing of English support, he was looking towards Russia and Persia. At the same time he declared his wish to be on friendly terms with England. Meanwhile Lord Auckland, Governor-General of India, had adopted a policy of interference and now undertook to restore Shah Sujah. In 1839 an Anglo-Indian army invaded Afghanistan and occupied Kabul, Shah Sujah being nominally placed on the throne, and in 1840 Dost Mohammed delivered himself up to the British. Thereupon the Afghan tribes rose under Akbar, the son of the captive Ameer. In January, 1842, the British army left Kabul to return to India and was trapped in the Afghan defiles and annihilated. The advance of an army under General Pollock by way of the Khyber Pass enabled the British to recover from their defeat and overthrow Akbar; but Shah Sujah had been assassinated soon after the English left him at Kabul. In 1842 Dost Mohammed was allowed to return to his country and resume his interrupted reign. He assisted the Sikhs during their war with the British, but after the occupation of the Punjab he concluded a treaty with the Anglo-Indian government in 1855. In 1863 Dost Mohammed added to his dominions the Province of Herat, which had remained independent since the expulsion of Mohammed from Kabul. He died May 29, 1863, having directed that his son Shere

Ali (q.v.) should succeed him. Dost Mohammed had a certain rugged barbaric honesty not always found in Oriental princes. In spite of his hard experience with the government, he always leaned to the side in the frontier politics which involved Russia, Persia, Great Britain, and Afghanistan. He showed statesman-like qualities in external and internal affairs and brought a measure of order into the Afghan chaos. Consult Mohan Lal, *Life of the Amir Dost Mohammed, Khan of Kabul* (London, 1846). See AFGHANISTAN.

DOSTOYEVSKY, dōs'tō-yěv'skē, FRÉDOIR MIKHÁYLOVITCH (1821-81). A famous Russian novelist, the son of a Moscow physician. His home training was one of strict discipline and undue formalism. Reading early developed into a passion with him—a passion much favored by a lack of outdoor life and by the pedantic character of his home influence. In 1834 he entered a famous Moscow boarding school, from which he returned to his country home only during vacations, when he studied with great interest the peasant community in which he found himself. He was still an omnivorous reader, but his reading was gradually losing its desultory character. At 17 he entered the School of Engineering at St. Petersburg. On graduation he obtained a position in the Department of Engineers in 1843, but gave it up a year later for literary pursuits, making his début with *Poor People* (1846). A number of other sketches followed, and Dostoyevsky's head was full of literary plans and projects when, suddenly, a halt was called to them all. In 1849, for his connection with the revolutionary plot of Petrashevsky, he was condemned to death. On the scaffold, this sentence was commuted to hard labor in Siberia. During the years in prison he gave way to religious mysticism. Pardonned in 1855 by Alexander II, he resumed his literary activity at St. Petersburg, after five years' interruption, and remained hard at work till the end of his life. The first fruit of this renewed activity was *The Down-trodden and Oppressed*, his first long novel, published serially in the magazine *Vremya* ('The Times'), then newly founded and published in conjunction with his brother. This was followed by *Memoirs from a Dead House* (1861-62), wherein were related his own experiences in prison. He then became an ardent Slavophile and mystic, with a tendency towards absolutism, and his *Crime and Punishment* (1866) marked his break with the Liberals and Radicals. In his periodical, in his *Author's Diary*, in his *The Brothers Karamazov* (1879-80, unfinished), and other works, these new tendencies became more and more marked. The Liberals were almost reconciled with him after his famous speech at the banquet on the occasion of the unveiling of Pushkin's monument at Moscow in 1880.

His works are seriously deficient from the purely technical point of view, the language is rarely polished, and he lacks a sense of proportion. His power of psychological analysis, however, especially of pathological conditions, aided as he was in this by his complete self-identification with the lowly and degraded characters depicted, is unique in literature. The accuracy and the scientific value of his pictures are fully attested by great Russian criminologists. The last edition of his works, in six volumes, was published at St. Petersburg in 1904. English translations of the following works have appeared: *Crime and Punishment* (New York,

1886); *Poor Folk* (London, 1894); *Prison Life in Siberia* (ib., 1886); *The Idiot* (ib., 1887); *Uncle's Dream* and *The Permanent Husband* (ib., 1888); *The Brothers Karamazov* (New York, 1912); *Letters from the Underworld and Other Tales* (New York and London, "Everyman's Library," 1914). Consult: Brandes, *Dostoyevsky* (Berlin, 1889); Hoffmann, *F. M. Dostoyevsky* (ib., 1899); Koni, "Dostoyevsky criminaliste," in *Revue Internationale de Sociologie* (Paris, 1898); Phelps, "Dostoyevsky," in *Essays on Russian Novelists* (New York, 1912); Lloyd, *A Great Russian Realist* (New York, 1912); Merezhkovsky, "Tolstoi and Dostoyevski," in *Tolstoi, as Man and Artist* (ib., 1902).

DOT. See PEERYBINGLE, MRS.

DOTARD (so called from alleged stupidity). A name formerly applied by sailors to various Arctic seals, especially in Newfoundland, and to a young harbor seal (*Phoca vitulina*).

DOTEN, CARROLL WARREN (1871-). An American statistician, born at Panton, Vt. He graduated in 1895 from the University of Vermont; taught there until 1903, meanwhile taking an M.A. at Harvard (1902); and was an instructor at Massachusetts Institute of Technology from 1903 to 1905, when he was made assistant professor of economics. He also directed the research work of the Boston School for Social Workers (1907-09) and served as expert special agent for the United States Census Bureau (1909). In 1906 he became secretary of the American Statistical Association and in 1910 chief investigator of the Massachusetts Commission on Compensation for Industrial Accidents. His publications include statistical papers, monographs, and reports such as *Recent Railroad Accidents in the United States*.

DOTHAN, dō'than. A city and the county seat of Houston Co., Ala., 119 miles by rail southeast of Montgomery, on the Atlantic Coast Line, the Central of Georgia, and the Atlanta and St. Andrews Bay railroads (Map: Alabama, D 4). It is an important commercial centre for that part of the State and has extensive compressed cotton and fertilizer interests, sash and door factories, and ice, cotton-oil, and lumber mills. It has several fine public buildings and a public library and owns its water works and electric plant. First settled about 1885, it was incorporated under a revised charter of 1901, is vested in a mayor, elected biennially, and a council of nine members. Pop., 1900, 3275; 1910, 7016.

DOTHEBOYS (dō'the-boiz) **HALL**. A Yorkshire school kept by one Squeers, in Dickens's *Nicholas Nickleby*, where Nicholas was assistant for a time—a picture of abuses in the country boarding-school system. The caricature was efficacious in causing the abolition of many similar educational horrors of Dickens's time.

DOTONID, dō-tō'nīd. A sea slug. See NUDI-BRANCHIATA, and accompanying Colored Plate.

DOTTEREL (OE. *dotrelle*, little doll, from *dotien*, to be stupid, Dutch, *dutten*, Icel. *dotta*, to nod from sleep). A reddish plover (*Charadrius*, or *Pluvialis*), which in summer inhabits the northern parts of Europe and Asia, breeding chiefly in the highest latitudes, and migrates on the approach of winter to the countries around the Mediterranean and those of similar climate. It appears in Great Britain as a bird of passage, but is now almost extinct,

GERARD DOU

PORTRAIT OF HIMSELF. FROM THE PAINTING IN THE DUCAL MUSEUM, BRUNSWICK

owing to the incessant shooting of it in spring and the taking of its eggs.

DOTTIN, HENRI GEORGES (1863-). A French Celtic scholar, born in Liancourt (Oise) and educated at the Laval Lycée, at Rennes, and at the Sorbonne. He taught at Dijon in 1891-92 and then at Rennes, where he was made professor of Greek in 1903 and dean of the faculty of letters in 1910. His article, "La littérature gaélique d'Irlande," in vol. iii of *Revue de Synthèse Historique*, contains a valuable bibliography; it has been translated and enlarged by Dunn, *The Gaelic Literature of Ireland* (1906). His publications include: *Glossaire des parlers du Bas-Maine* (1899); *Contes irlandais traduits du gaélique* (1901); *Contes et légendes d'Irlande traduits* (1901); *Manuel pour servir à l'étude de l'antiquité celtique* (1905); *Louis Eumius, mystère breton* (1911); *Manuel d'irlandais moyen* (1913). He edited the *Revue Celtique*.

DOTY, ALYAH HUNT. An American physician. He graduated from the Bellevue Hospital Medical College (New York University) in 1878. He was health officer of the Port of New York until 1911, and he also lectured on quarantine sanitation at Bellevue. In 1913 he was appointed medical director for the Employees' Benefit Fund Committee of the American Telephone and Telegraph Company, the Western Union Telegraph Company, and the Western Electric Company. He is author of a *Manual of Instruction in the Principles of Prompt Aid to the Injured* (1889; 6th ed., 1913); *Prevention of Infectious Diseases* (1911); *The Mosquito: Its Relation to Disease and its Extirpation* (1912).

DOU, DOW, or DOUW, GERBET (GERARD) (1613-75). A Dutch genre painter. He was born at Leyden, April 7, 1613, and apprenticed first to an engraver and later to Pieter Kouwenhoven, a painter on glass; but his real master was Rembrandt, with whom he studied at Leyden, and to whom he was indebted for his skill in chiaroscuro. He first devoted himself to portrait painting, in which he achieved great success; good examples are his two portraits of himself in the Dresden Gallery and of Rembrandt's parents in Cassel. But genre subjects were better fitted to display his genius, and he excelled in simple domestic scenes, painted with infinite attention to detail. He would depict a broomstick or a pan of vegetables with as much carefulness as the figures that were introduced. It is said that he not only prepared his own brushes and pounded his colors, but worked with his own hands at everything required in the construction of a picture. Dou often painted with charming effect the artificial light produced by candle or lantern. His picture "The Evening School" (Rijks-Museum, Amsterdam) is the best example of candlelight effect. Along with the "Young Mother" (1658, Mauritshuis, Hague), it ranks among his very best works.

Other fine examples are the "Woman Sick of the Dropsy" (1663), "The Bible Reader," and the "Grocer Woman," in the Louvre; the "Girl at the Window," the "Schoolmaster," the "Hermit," and others, at Dresden; the so-called "Portrait of Dou's Wife" and the "Poulterer's Shop," in the National Gallery. He painted upward of 300 works and ranks as one of the most important Dutch genre painters, whose pictures were more sought after at home and abroad than any other of his day. His color

is soft and harmonious, his treatment of light and shade masterly, his draftsmanship (except during his last years) impeccable; but he is often tiresome in his excessive attention to detail. Among his pupils were Franz van Mieris, Gabriel Metsu, Van Slingeland, and Schalken; and the Leyden School of genre, which he founded, continued its activity until the middle of the nineteenth century. Consult: Van Dyke, *Old Dutch and Flemish Masters* (New York, 1895); Martin, *Gerard Douw* (Leyden, 1901; Eng. trans. by Bell, London, 1902 and 1908); also Martin, in *Klassiker der Kunst* (Stuttgart and Berlin, 1913).

DOUAI, or DOUAY, dōw'ā. A town of France, in the Department of Nord, situated on the river Scarpe, about 20 miles south of Lille. (Map: France N., J 2). Among the manufacturing establishments are salt and sugar refineries, ironworks, a cannon foundry, glass, bottle, and chemical works, breweries, and file factories, and there is an active trade in corn, seed, and linen. The town possesses a library of 96,000 volumes and a scientific and archaeological museum. There are many buildings dating back to the sixteenth and seventeenth centuries, and the church of Notre Dame was built in the twelfth century. Pop., 1901, 33,649; 1911, 36,314. It was held by the dukes of Burgundy after 1384, from whom it passed into the possession of the Hapsburgs. It was taken by Louis XIV in 1667, lost in 1710, and retaken in 1712. Douai was the seat of a celebrated seminary for English Catholics, founded by Cardinal Allen in 1568. It was formerly also the seat of a Catholic university. An English Benedictine seminary exists here. For the Douai Bible, see BIBLE.

DOUARNENEZ, dōw'ār-ne-nēs' or -nēf (Bret., Land of the Isle, alluding to the island of Tristan opposite). A seaport of Brittany, France, on a bay of the same name in the Department of Finistère. It has some shipbuilding, and its extensive sardine fisheries employ 4,000 men annually. Rope and net making is also carried on. Pop., 1901, 12,865; 1911, 13,753.

DOUAY. See DOUAI.

DOUAY, FÉLIX CHARLES (1816-79). A French general. He served in the wars in the Crimea, in Italy, and in Mexico, and for bravery at Magenta and Solferino he was made a brigadier general. In the Franco-German War he led the Seventh Army Corps, and he was taken prisoner at Sedan. As commander of the Fourth Army Corps, organized against the Communes, he was the first to enter Paris (May 22, 1871) and saved the Louvre from entire destruction.

DOUBLE BASS. The largest instrument of the violin family in common use. The double bass is the foundation of the orchestra, for to it is given the lowest part of the harmony. It probably received its name because it often doubles in the lower octave the bass of the harmony given to the bassoon, violoncello, or some other instrument. Not before the beginning of the nineteenth century were independent parts assigned to this instrument. It appears first about the beginning of the seventeenth century. Its origin is attributed to Gaspar di Salò in 1580, but he may have only added improvements to an instrument that already existed. The double bass was first used in the orchestra about 1696. It was originally mounted with three strings, but is now used with four strings

tuned in E₁, A₁, D, and G, and the notes sound an octave lower than written. Its compass is from E₁ to a. The double bass is an orchestral rather than solo instrument, but a few persons have excelled as virtuosi upon it, e.g., Dragonetti (q.v.), Bottesini (q.v.), and at the present day Kussewitzky (q.v.). The instrument is sometimes called a contrabass. Consult F. Warnecke, *Der Kontrabass: Seine Geschichte und Zukunft* (Hamburg, 1911). See BASS, and Plate of VIOLINS.

DOUBLE COCONUT. See SEYCHELLES COCONUT.

DOUBLE CONSCIOUSNESS. A morbid mental condition, also known as double personality, observed in cases of hysteria, hypnosis, and trance, characterized by the existence of two or more independent, self-consistent groups of conscious processes which alternate periodically or are called up in irregular sequence as favorable circumstances arise. Usually these groups are strictly separated from one another, so that, while the one group is in operation, the other is utterly shut out from consciousness—a fact which, from the purely psychological point of view, stamps the phenomenon as an instance of general derangement of memory. When the two sets of ideas become complex, and the mutual obliviscence is complete, each group develops that “aura” of sensations and feelings which constitutes selfhood; and the individual whose mind is thus partitioned may be rightly said to possess a “double” or “secondary personality.” When this division of mentation is radical, there is oftentimes exhibited a curious antithesis between the types of the two personalities—a condition popularly set forth, in an exaggerated degree, in Stevenson’s *Dr. Jekyll and Mr. Hyde*.

The ultimate basis of double consciousness must be sought in certain physiological conditions of the central nervous system. Partial light is thrown upon the conditions which favor the mental schism by the frequent demarcation of the two “selves” by specific antithetical moods. This feature makes it probable that the organic sensations, the chief determinants of our general mood or temper, may constitute the nucleus around which are gathered the remaining elements of the segregated “personality.” This function of the somatic elements of consciousness is well illustrated in Flournoy’s study of a remarkable case of divided consciousness, that of the medium “Mademoiselle Smith,” who “incarnates” several distinct personalities, and whose “guiding spirit” has his origin, in Flournoy’s judgment, in the sexual cœnæsthesis of the subject.

Prince, again, describes in detail a case in which there are three highly developed personalities besides several lesser ones. He concludes that the normal consciousness tends to break up into separate groups of processes, which may become completely dissociated from one another, and which tend under frequent recurrence to develop into independent personalities. His explanation, however, is couched, not in physiological terms, but in terms of a “subconscious” mental life, in which the several personalities are continuous and thus coexistent, though at a given time one alone rises to the rank of “primary consciousness,” i.e., the consciousness of which the “primary self” is aware. This concept of the subconscious or “co-conscious” is convenient for exposition, but throws

no light on the physiological principles to which we must go for our final explanation.

Finally, double consciousness may be regarded as, in a certain sense, merely an exaggeration of what is termed “motor automatism”—a condition which is often present, or at least easily developed, in the normal consciousness. Solomons and Stein have shown experimentally that there exists “a complete analogy between the performances of the second personality and the automatic acts of normal persons.” They were able, by practice, to cultivate automatisms of a complicated nature, such as spontaneous automatic writing and reading. If, e.g., A reads aloud to B, who simultaneously dictates to A, and the reading is sufficiently interesting, B will unconsciously dictate sentences which A unconsciously writes. It remains to be added that hypnosis furnishes excellent examples of the alternation of consciousnesses. Subjects who when awakened are totally ignorant of their hypnotic experiences, may in a succeeding hypnosis return without break to the consciousness of the former somnambulistic state. Consult: Flournoy, *From India to the Planet Mars* (New York, 1900); Kuelpe, *Outlines of Psychology*, trans. by Titchener (London, 1909); Wundt, *Lectures on Human and Animal Psychology*, trans. by Creighton and Titchener (ib., 1901); Dessir, *Das Doppel-Ich* (Leipzig, 1889); Janet, *L’Automatisme psychologique* (Paris, 1891); Prince, *The Dissociation of a Personality* (New York, 1906).

DOUBLEDAY, ABNER (1819–93). An American soldier. He was born at Ballston Spa, N. Y. At Cooperstown, N. Y., in 1839 he helped draw up the first baseball rules in the United States. He graduated at West Point and was assigned as brevet second lieutenant of artillery in 1842. He served in the First Artillery during the Mexican War and participated in the battles of Monterey and Buena Vista. He was stationed at Fort Moultrie at the breaking out of the Civil War and took part in the defense of Fort Sumter. A month later he was promoted major and served with General Patterson in the Shenandoah valley, and on Feb. 3, 1862, he was made a brigadier general of volunteers and placed in command of the defenses of Washington. He commanded a division at the battle of Bull Run and at Antietam. He became a major general of volunteers in November, 1862; fought at Fredericksburg, Chancellorsville, and at Gettysburg, where on the first day of the battle, when General Reynolds fell, he commanded the troops in the field for several hours. He continued to serve (as colonel in the Thirty-fifth Infantry) in the regular army after the war, but retired in 1873. He published *Reminiscences of Forts Sumter and Moultrie in 1860–61* (1876), and *Chancellorsville and Gettysburg* (1882) in the “Centennial of the Civil War Series.”

DOUBLEDAY, FRANK NELSON (1862–). An American publisher, born in Brooklyn, N. Y., and educated at Brooklyn Polytechnic Institute. He was connected with Charles Scribner’s Sons from 1877 to 1895, during which time he re-founded and edited *The Book Buyer* (1884) and served as manager of *Scribner’s Magazine* after it was established in 1886. From 1897 to 1900 he was a member of the publishing house of Doubleday & McClure Co., and he then became president of Doubleday, Page & Co., publishers of *Country Life in America*, *The World’s Work*,

The Garden Magazine, and *Farming*, and of books in all departments of literature.

DOUBLEDAY, NELTJE DEGRAFF ("NELTJE BLANCHAN") (1865-). An American writer on nature, born in Chicago. She married Frank Nelson Doubleday in 1886. In addition to pamphlets and ... articles she is author of: *The Pie* ... (1894); *Bird Neighbors* (1897; 4th ed., 1904); *Birds that Hunt and Are Hunted* (1898; 3d ed., 1905); *Our Wild Flowers and their Insect Visitors* (1900); *How to Attract the Birds* (1902); *Birds Every Child Should Know* (1907); *The American Flower Garden* (1909; 2d ed., 1913).

DOUBLE DRAGON, ORDER OF THE. A Chinese military order with five grades. It was established in 1865 for the purpose of rewarding European officers who had been of service to China, but was extended to other classes in 1882. See Plate II of ORDERS.

DOUBLE EYE, or FOUR-EYES. See ANA-BLEPS.

DOUBLE FERTILIZATION. See FERTILIZATION.

DOUBLE FLOWER. See FLOWER.

DOUBLE MARRIAGE, THE. A tragedy by Fletcher and Massinger (1619), printed in 1647.

DOUBLE PERSONALITY. See DOUBLE CONSCIOUSNESS.

DOUBLE REFRACTION. See LIGHT.

DOUBLE STARS. As seen by the naked eye, all stars appear to be single, but the telescope shows us that many are double, while it resolves others into several distinct bodies. In some instances telescopes of low power suffice to reveal the separation; others require instruments of the largest kind. It is not possible to decide by a single observation whether these stars are "optical" doubles, of which the two components are merely projected upon contiguous points of the sky, or true "binary" systems, whose components are really near each other in space. But if the lapse of time reveals to observers an orbital motion of the components, it is safe to assume that we have to deal with a pair of stars physically connected—a double star, as it were. About 15,000 double stars are known, and of these some 700 are almost certainly binary. Their periods of revolution range from five and a half years up to perhaps 10 centuries.

In addition to these optical doubles and binary systems observed visually with the telescope, astronomers have discovered a number of so-called "spectroscopic" binaries. These have an orbital revolution which is often extremely short, and the components are so near together that they cannot be separated in the ordinary way by the most powerful telescopes. But a study of their spectra reveals a duplication of the spectral lines, explicable only on the theory that we have to do with a double source of light. Periodicity in this duplication then allows the observational determination of the time of orbital revolution in the double system. See STAR.

DOUBLET (from *double*; cf. OF. *doublier*, *doublour*, lining of a garment; so called from being originally lined or wadded for defense). A close, tight-fitting garment with or without sleeves, reaching a little below the girdle. It was almost identical with what was afterward called the jerkin, which, as a matter of strict chronology, belongs rather to the sixteenth and seventeenth centuries. The sleeves were sometimes detachable, being tied on the arms. In

its various forms the doublet was the forerunner of the modern coat, jacket, and waistcoat. See COSTUME.

DOUBLET. An imitation gem, usually made by cementing a thin layer of a genuine gem by means of a colorless gum, such as mastic, on the line of the girdle, to a piece of glass that has been colored to imitate the real gem. See GEMS, IMITATION AND ARTIFICIAL.

DOUBS, dōō (ancient, *Dubis*). An eastern department of France, separated from Switzerland by the Jura Mountains (Map: France, N., M 5). Area, 2030 square miles. Pop., 1901, 298,864; 1911, 299,935. Doubs is traversed by the river Doubs (highest point Mont Dore, 4800 feet), a tributary of the Saône, the Des-soubre and the Loue. The surface is hilly, being crossed by four parallel ranges of the Jura Mountains. The climate is more rigorous than in most similar latitudes of Europe. Pine, walnut, and common orchard trees thrive well; mines of iron and coal are worked; and gypsum, building stone, lime, and marble are abundant. The trade is principally in iron, cattle, horses, and dairy products. It is famous for its cheese. Capital, Besançon. The department was formed out of part of the old Franche-Comté.

DOUBTING CASTLE. In Bunyan's *Pilgrim's Progress*, the dwelling of Giant Despair.

DOUBTING INSANITY. A form of melancholia (q.v.).

DOUC, dōōk (Fr. *douc*, of uncertain etymology). A small monkey (*Semnopithecus*, or *Pygathrix nemaus*) of Cochín-China, curiously variegated with black, white, and red. It is a little more related to the hanuman (q.v.).

DOUCET, dōō'sā', CHARLES CAMILLE (1812-95). A French dramatist, born in Paris. He wrote *Léonce* (1838) in collaboration with Bayard, and the play was followed by several comedies in verse. These have been collected and published under the title *Comédies en vers* (1858). The most successful of his plays was *La considération* (1860). He was elected a member of the Academy in 1865. His *Œuvres complètes* were published in 1874.

DOUCET, HENRI LUCIEN (1856-95). A French figure and portrait painter. He was born in Paris, studied there under Lefebvre and Boulanger, and in 1880 won the Prix de Rome. His pictures are usually piquant, sparkling representations of modern life, eminently Parisian in style, but the audacious realism of his earlier work is not maintained in his later, which is somewhat characterless. His portraits in pastel also are notable. His most widely known picture is "Après le bal" ('After the Ball,' 1889). Other excellent examples are the portraits of Madame Galli-Marie as "Carmen" (1884, Marseilles Museum), the Princesse Mathilde and "My Parents" (1890, Lyons Museum); "A Spanish Woman" (Pontoise Museum), and a "Nude Figure" (1890). He was awarded a first-class medal for pastel in 1889 and the decoration of the Legion of Honor in 1891.

DOUCHE. dōōsh. See BATH; HYDROTHERAPY.

DOUGALL, dōō'gal, LILY (1858-). A Canadian novelist, born in Montreal. She completed her education at the universities of Edinburgh and St. Andrews and passed much of her time at Melbourne, in Derbyshire, England. The scope of her work extends from Canadian themes to a portrait of the new woman. Among her popular novels are: *Beggars All* (1891);

What Necessity Knows (1893); *The Mermaid* (1895); *Zeitgeist* (1895); *Question of Faith* (1895); *The Madonna of a Day* (1896); *A Dozen Ways of Love* (1897); *The Mormon Prophet* (1898); *The Earthly Purgatory* (1904); *The Spanish Dowry* (1906); *Paths of the Righteous* (1908).

DOUGH BIRD. See CURLEW.

DOUGHFACE. A contemptuous nickname applied before the Civil War to any Northern man who was accused of truckling to the slave power. Lowell explains the term in his glossary to the *Biglow Papers* as meaning "a contented lickspittle, a common variety of Northern politicians," and makes his "pious editor" say:

"For any office, small or gret,
I couldn't ax with no face,
'thout I'd ben, thru dry an' wet,
Th' unrizzest kind o' doughface."

Works, viii, 102.

The term was probably first used in this connection by John Randolph, of Roanoke, who in 1820 referred to the eighteen Northern Congressmen who had supported the Missouri Compromise as "Northern Doughfaces."

DOUGHTY, do'ti or do'ti, ARTHUR GEORGE (1860-). A Canadian historian and archivist. He was born at Maidenhead, England, and was educated at New Inn Hall (later part of Balliol College), Oxford, and Dickenson College, Carlisle. He afterward prepared to enter the church, and was associated with All Hallows' Mission, Southwark, London; but later he came to Montreal to engage in commercial pursuits and was a music and dramatic critic for newspapers and 1901-04 he was joint librarian Legislature, and in the latter year was appointed Dominion archivist and keeper of the records. He was created a C.M.G. in 1905. In 1912 he was appointed a deputy minister. His principal publications are: *The Life and Work of Tennyson* (1893); *The Siege of Quebec*, with G. W. Parmelee (2 vols., 1901-02); *Quebec under Two Flags*, with N. E. Dionne (1903); for *Supremacy* (1905); *Documents the Constitutional History of Canada*, with Adam Shortt (1907); *The Cradle of New France* (1908); *Index and Dictionary of Canadian History*, with L. J. Burpee (1911). In 1912 he and Adam Shortt became general editors of a projected work in 22 volumes entitled *Canada and its Provinces: A History*. In 1913 several volumes had been published.

DOUGHTY, CHARLES MONTAGUE (1843-). An English explorer. He was born at Theberton Hall, Suffolk, and was educated at Cambridge. During a sojourn of two years in Arabia he made a valuable study of the geography, archaeology, and ethnography of the country, the results of which were afterward embodied in the work entitled *Travels in Arabia Deserta* (1888). He received the Royal medal of the Royal Geographical Society in 1912. His writings include: *Documents epigraphiques* (1884); *The Dawn of Britain* (6 vols., 1906); *Adam Cast Forth* (1908); *The Cliffs* (1909); *The Clouds* (1912).

DOUGHTY, THOMAS (1793-1856). An American landscape painter, born in Philadelphia, Pa. He had hardly any instruction in art and was 30 years old when he took up painting as a profession. A highly successful exhibition of paintings in Boston in 1831 gave him a national reputation and enabled him to travel

abroad; but later he suffered greatly through lack of appreciation. Doughty was the precursor of the Hudson River school. Although his works now possess chiefly a historic interest, their fidelity to nature, luminous, silvery tone, and wide perspective give them undoubted poetic charm. They are, moreover, entirely independent of foreign models. Among his best paintings are: "A View of the Schuylkill" (Edinburgh Museum); five works in the Pennsylvania Academy of Fine Arts, Philadelphia; "On the Hudson" and "A River Glimpse" (Metropolitan Museum, New York).

DOUGLAS, düg'las (Ir. *Dubh-ghlaise*, black stream). The capital and principal seaport of the Isle of Man, situated on the margin of a highly picturesque bay on the east side of the island (Map: England, B 2). It has become an important e. The old town, standing on the edge of the bay, with narrow, tortuous streets, has mostly given way to the handsome modern terraces and villas which occupy the rising ground beyond. A fine promenade skirts the edge of the bay. The Tower of Refuge, a castle-like structure, occupies a dangerous rock in the southern area of the bay, called Conister, and was erected in 1833 for the safety of shipwrecked mariners. Douglas was incorporated in 1895, and since that date much has been done by the authorities to promote the prosperity of the town. The water supply has been municipalized; many improvements in streets, promenades, etc., have been carried out; new municipal buildings and artisans' dwellings have been erected. The tramways were acquired by the municipality in 1902, and in 1906 an elaborate public-bathing service was established. The town maintains a public library, markets, and Douglas is the principal packet island and is in steamship communication with Liverpool, Belfast, Dublin, and Glasgow. Pop., 1901, 19,223; 1911, 21,101.

DOUGLAS. A city in Cochise Co., Ariz., 33 miles southeast of Bisbee, on the El Paso and Southwestern Railroad, and the terminus of the Nacozari Railroad of Mexico (Map: Arizona, F 6). It contains two of the largest copper smelters in the United States, gypsum, cement, and plaster works, and a brewery. Two miles distant from the city, on the Mexican side, is the battlefield of Agua Prieta. The water works are owned by the municipality. Pop., 1910, 6437.

DOUGLAS. A city and the county seat of Coffee Co., Ga., 43 miles northwest of Waycross, on the Atlanta, Birmingham, and Atlantic, and the Georgia and Florida railroads (Map: Georgia, D 4). It contains an agricultural college and a normal school. There are cotton gins, an oil mill, saw and grist mills, novelty works, and a turpentine and rosin factory. The city owns its water works and electric-light plant. Pop., 1900, 617; 1910, 3550.

DOUGLAS. A family of great prominence in the history of Scotland. The legend of the sixteenth or seventeenth century, attributing its rise to the bravery of Sholto Douglas in 770, is impossible from the details of the legend itself. Nor can any connection be traced, as Chalmers supposed there could be, between the Douglasses and the Fleming Theobald, who held the lands on Douglas water from 1147 to 1164.

WILLIAM OF DOUGLAS appears as a witness

of charters in 1175 and 1213. He was doubtless so called from the vale of Douglas, in Lanark, which he held. His son Bruce was made Bishop of Murray in 1203.—**SIR ARCHIBALD**, or **ERKENBALD**, of **DOUGLAS**, who appears in charters between 1190 and 1232, was the first of the family to attain the rank of knighthood. Besides the family inheritance he held land under the monks of Dunfermline and the Earl of Fife, and in Clydesdale through his wife, one of the heiresses of Sir John Crawford. His son, **SIR WILLIAM**, figures in charters from 1240 to 1273, and appears in 1255 as a Scottish partisan of Henry III of England in the baronial wars and was granted the manor of Faudon in Northumberland by the future Edward I. His son, **SIR HUGH**, died in 1287, and was succeeded by his brother, **WILLIAM THE HARDY**, as he is called in family traditions, a daring and restless man. He was the first man of influence to join Wallace in his rising against the English, but soon deserted him, submitting to his old patron, King Edward I, to whom he had again and again sworn fealty. He was sent prisoner to the Tower of London, where he died in 1298. It appears that he possessed lands in one English and in seven Scottish counties—Northumberland, Berwick, Edinburgh, Fife, Lanark, Ayr, Dumfries, and Wigton.

The history of his son, the **GOOD SIR JAMES OF DOUGLAS**, is familiar to every one, as Bruce's greatest captain in the long War of the Succession. The hero of 70 fights, he is said to have won them all but 13, leaving the name of the "Black Douglas"—so he was called from his swarthy complexion—as a word of fear by which English mothers stilled their children. He was slain in Andalusia, in 1330, on his way to the Holy Land with the heart of his royal master, and was succeeded by his son, **WILLIAM, LORD OF DOUGLAS**, who was slain at Halidon in 1333.—**SIR ARCHIBALD L. DOUGLAS** (1296–1333), a younger brother of the Good Sir James, was a prominent Scottish leader during the minority of David II. In 1332 he surprised and defeated Edward de Baliol, the rival claimant of the throne. He was made Regent of Scotland in 1333 and in the same year invaded England, but was defeated and slain at Halidon. In 1357 **SIR WILLIAM OF DOUGLAS**, son of the Regent of Scotland, who had fought at Poitiers and elsewhere, himself in other fields, was made Earl of Douglas and afterward, by marriage, became Earl of Mar. In 1371 he even disputed the succession of the Scottish crown with Robert II, the first of the Stuarts, which he claimed as a descendant of the Baliols and Comyns. His pretensions were abandoned only on condition that his son should marry the King's daughter. He died in 1384. His son, **JAMES**, second Earl of Douglas and Mar, the conqueror of Hotspur (q.v.), fell at Otterburn in 1388; and, as he left no legitimate issue, the direct male line of William the Hardy and the Good Sir James now came to an end.

The Earldom of Douglas, meanwhile, was bestowed on an illegitimate son of the Good Sir James—**ARCHIBALD**, Lord of Galloway, surnamed the Grim. By his marriage with the heiress of Bothwell he added that barony to the Douglas domains; and, having married his only daughter to the heir apparent of the Scottish crown, and his eldest son to the eldest daughter of the Scottish King, he died in 1400 or 1401. His son and successor, **ARCHIBALD**, fourth Earl of Douglas,

was, from his many misfortunes in battle, surnamed "the Tyneman"—i.e., the loser. He was taken prisoner at Homildon (1402), and at Shrewsbury in the following year. Repairing to France, he was there made Duke of Touraine, and fell at Verneuil in 1424. He was succeeded by his son **ARCHIBALD**, who distinguished himself in the French wars and, dying in 1439, was buried in the church of Douglas, where his tomb still remains. His son and successor, **WILLIAM**, a boy of 16, by the splendor of his court aroused the fear of the Scottish King, and was treacherously beheaded in Edinburgh Castle in 1440. His French duchy and county died with him; his Scottish earldom was bestowed on his grand-uncle (the second son of Archibald the Grim), **JAMES**, surnamed the Gross, who in 1437 had been made Earl of Avondale. He died in 1443, being succeeded by his son **WILLIAM**, who, by marriage with his kinswoman (the only daughter of Archibald, fifth Earl of Douglas, and second Duke of Touraine), again added the lordship of Galloway to the Douglas possessions. He was for a time all-powerful with King James II, who made him lieutenant general of the realm; but, afterward losing the royal favor, he seems to have entered into a confederacy against the King, by whom he was killed in Stirling Castle in 1452. Leaving no child, he was succeeded by his brother **JAMES**, who in 1454 made open war against King James II as the murderer of his brother and kinsman (the sixth and eighth Earls of Douglas). The issue seemed doubtful for a time; but, the Hamiltons and others being gained over to the King's side, Douglas fled to England. The struggle was still maintained by his brothers—**Archibald**, who by marriage had become Earl of Murray, and **Hugh**, who in 1445 had been made Earl of Ormond. They were defeated at Arkinholm in May, 1455, Murray being slain on the field and Ormond taken prisoner and afterward beheaded. Abercorn, Douglas, Strathaven, Thrieve, and other castles of the Douglasses, were dismantled, and the Earldom of Douglas came to an end by forfeiture, after an existence of 98 years, during which it had been held by no fewer than nine lords. The last Earl lived many years in England, where he had a pension from the crown and was made a knight of the Garter. In 1484 he leagued himself with the exiled Duke of Albany to invade Scotland. He was defeated at Lochmaben, but James III spared his life on condition of his taking the cowl. He died in the abbey of Lindores in April, 1488; and so ended the elder illegitimate line of the Douglasses.

Earls of Angus. This line was begun with **GEORGE**, the illegitimate son of William, first Earl of Douglas, and Margaret Stewart, Countess of Angus and Mar. He received a grant of his mother's Earldom of Angus in 1389, married in 1397 the youngest daughter of King Robert II, was taken prisoner at Homildon in 1402, and died of the plague in England in the following year. He was succeeded by his son, **WILLIAM**, who, dying in 1437, was succeeded by his son **JAMES**, who died without issue, when the title reverted to his uncle, **GEORGE**, fourth Earl of Angus, took part with the King against the Douglasses in 1454: his loyalty was rewarded by a grant of their old inheritance of Douglasdale; and so, in the phrase of the time, "the Red Douglas"—such was the complexion of Angus—"put down the Black." He died in 1462, being succeeded by his son **ARCHIBALD**, surnamed Bell-

the-Cat, and sometimes also called the Great Earl. After filling the highest offices in the state and adding largely to the family possessions, he retired to the priory of Canons Regular at Whithorn, in Galloway, where he died about 1514. He was succeeded by his grandson ARCHIBALD, who in 1514 married the Queen Dowager of Scotland, Margaret, sister of Henry VIII of England and widow of James IV of Scotland. The fruit of this marriage was a daughter, Margaret, who, marrying the Earl of Lennox, became the mother of Henry, Lord Darnley, the husband of Queen Mary and father of King James VI. The Earl of Angus had for a time supreme power in Scotland; but in 1528 the young King James V escaped from his hands, and sentence of forfeiture was passed against Angus and his kinsmen. The King swore that while he lived the Douglasses should have no place in his kingdom, and he kept his vow. On his death, in 1542, Angus returned to Scotland and was restored to his honors and possessions. He died at Tantallon in 1556. His nephew, who succeeded him, died two years afterward, leaving an only son, ARCHIBALD, eighth Earl of Angus. This Good Earl, as he was called, died in 1588, when his title devolved on his kinsman WILLIAM, the grandson of Sir William Douglas of Glenbervie, second son of Archibald Bell-the-Cat. Dying in 1591, he was succeeded by his son WILLIAM, who next year obtained from the crown a special recognition of his high privileges as Earl of Angus. He turned Roman Catholic, and died in Paris in 1611.

Marquises and Dukes of Douglas, and Lords Douglas. WILLIAM, eleventh Earl of Angus, was created Marquis of Douglas in 1633 and, dying in 1660, was succeeded by his grandson JAMES, who died in 1700, leaving issue one son and one daughter. The son, ARCHIBALD, third Marquis of Douglas, was created Duke of Douglas in 1703 and died childless in 1761, when his dukedom became extinct and his marquissate devolved on the Duke of Hamilton. The descendants of the sister, Lady Jane Douglas, were British peers, under the title Baron Douglas of Douglas Castle, from 1790 till 1857. The claims of the rivals to the Earldom of Angus in 1762 were never decided, and the title is still in abeyance. The right attached to it of bearing the crown of Scotland was debated before the Privy Council in 1823, when it was ruled that Lord Douglas's claim to that honor, being a claim of heritable right, fell for decision to a court of law. The motto of the Douglas arms, *Jamais arriere* ('Never behind'), probably alludes to the peculiar precedence inherent in their Earldom of Angus. The bloody heart commemorates Bruce's dying bequest to the Good Sir James; the three stars which the Douglasses bear in common with the Murrays seem to denote the descent of both from one ancestor.

Earls of Morton. SIR ANDREW OF DOUGLAS, who appears in record in 1248, was apparently a younger son of Sir Archibald, or Erkenbald, of Douglas, the second chief of the house. His son, WILLIAM OF DOUGLAS, swore fealty to King Edward I for his lands in West Lothian in 1296 and was probably the father of Sir James of Douglas—surnamed the Lothian, to distinguish him from his kinsman of Clydesdale—who in 1315 had a grant from Bruce of the lands of Kincavil and Calder-clere. He died about 1320, being succeeded by his son, SIR WILLIAM OF

DOUGLAS, of Liddesdale, who greatly enlarged the family possessions in Fife and elsewhere. The "Knight of Liddesdale"—as he was called by his contemporaries, who regarded him as "the flower of chivalry"—was assassinated in 1353 by his kinsman, William, first Earl of Douglas, to revenge his wife's dishonor. He was succeeded by his nephew, SIR JAMES OF DOUGLAS, of Dalkeith, a man of literary tastes, who entertained Froissart at his board and possessed a valuable library for the day. He was of great power and influence, and contracted princely alliances. His first wife was a daughter of "Black Agnes," the heroic Countess of Dunbar; his second was a sister of King Robert II; and he matched his eldest son, Sir James of Douglas, of Dalkeith, with a daughter of King Robert III. Their grandson married a daughter of King James I and in 1458 was created Earl of Morton. His grandson, the third Earl, dying without male issue in 1553, the earldom devolved on his daughter's husband, the Regent Morton, JAMES DOUGLAS, great-grandson of Archibald Bell-the-Cat. (See MORTON, JAMES DOUGLAS.) After his fall the title went to ARCHIBALD, eighth Earl of Angus; and when he died childless, in 1588, it passed to SIR WILLIAM DOUGLAS, of Lochleven, who thus became seventh Earl of Morton. His losses in the great Civil War compelled him, in 1642, to sell Dalkeith to the Earl of Buccleuch, and his Tweeddale and Eskdale lands to others; but Aberdour and other old domains of the family still remain with his descendant, the Earl of Morton, who descends legitimately in the male line from William of Douglas, the progenitor of the race in the twelfth century.

Other Branches. In the seventeenth century the descendants of Sir William Douglas of Drumlanrig, an illegitimate son of the hero of Otterburn, were created earls, marquises, and dukes of Queensberry, earls of March, and earls of Solway, of which titles only that of the Marquis of Queensberry remains in the family. During the same period younger branches of the family were earls of Selkirk, Forfar, and Dumbarton, and held other titles, of which that of the Earl of Selkirk is the only one not now dormant or extinct.

Bibliography. Hume of Godscroft, *A History of the House of Douglas and Angus* (Edinburgh, 1644; reprinted 1748), preserves the traditions of the family, but its accuracy is not to be trusted. The earlier history of the Douglasses has been critically examined by Chalmers in his *Caledonia*, vol. i (London, 1807); by Riddell in his *Remarks upon Scotch Peerage Law* (Edinburgh, 1833); by Cosmo Innes, in the *Registrum Episcopatus Moraviensis* (ib., 1837), and the *Liber S. Marie de Calchou*, vol. i (ib., 1846); and by Joseph Robertson, in the *Origines Parochiales Scotiæ*, vol. i (ib., 1851). The descent of the houses of Angus and Dalkeith was first ascertained by Riddell in his *Remarks upon Scotch Peerage Law*, pp. 154-164 (ib., 1833), and in his *Stewartiana*. The charters and correspondence of the Morton family have been edited for the Bannatyne Club by Mr. Cosmo Innes, in the *Registrum Honoris de Morton* (ib., 1853). Consult Maxwell, *A History of the House of Douglas* (London, 1902). This book contains an extensive bibliography on the Douglas family.

DOUGLAS, SIR ARCHIBALD LUCIUS (1842-1913). A British admiral, born at Quebec, Canada, and educated at the Quebec high school.

Having in 1856 joined the *Boscawen*, the flagship of the North American and West Indian stations, he became a lieutenant (1861), commander (1872), captain (1880), and vice admiral (1901). He served with the naval brigade that went up the Congo and the Gambia in 1860; in 1873-75 he was director of the Japanese Imperial Naval College. At various times he commanded the *Serapis* (Soudan, 1884), the *Edinburgh*, the *Cambridge*, and the *Excellent*; and he was commander in chief in the East Indies (1898-99), at the North American and West Indian stations (1902-04), and at Portsmouth, England (1904-07). From 1896 to 1898 he served as vice president of the ordnance committee, and from 1899 to 1902 he was Lord of the Admiralty. He retired in 1907. In 1893-95 he was aid-de-camp to Queen Victoria, he was created G.C.V.O. in 1905 and G.C.B. in 1911, and he received also several foreign decorations.

DOUGLAS, SIR CHARLES WHITTINGHAM HORSLEY (1850-1914). A British soldier. In 1869 he joined the Ninety-second Regiment, with whom he served during the Boer War (1879-80). In the following year he took part in the Boer War, in 1884 he acted as quartermaster-general in the Suakim expedition, and after home service at Aldershot (1893-98) he was actively engaged in the South African War. At its close he was promoted major general. Returning to England, he commanded the First Infantry Brigade (1901), the Second Division of the First Army Corps (1902-04), and the Chief Southern Command (1909-12). He was second military member of the Army Council and adjutant general of the forces in 1904-09 and inspector general from 1912 to 1914. In the latter year he was further promoted, being appointed Chief of the Imperial General staff, succeeding Field Marshal Sir J. D. P. French at the time of the Ulster crisis. (See *IRELAND, History*.) General Douglas was created G.C.B. in 1911.

DOUGLAS, DAVID (1798-1834). A Scottish botanist and traveler, born at Scone, Perthshire. He visited the United States in behalf of the Royal Horticultural Society in 1823. In his capacity as a collector he set out on a tour to the Pacific in 1824 and in the following year reached Fort Vancouver. It was on this scientifically fruitful journey that he discovered *Pseudotsuga douglasii*, the well-known "Douglas spruce." Although the name of the species should probably be *P. mucronata*, the common name will always commemorate Douglas. After another sojourn of five years in California and British Columbia he visited the Sandwich Islands in 1834, where he died from wounds inflicted by an infuriated bull. He introduced into botany more than 150 specimens of trees and plants indigenous to America.

DOUGLAS, ELLEN. A character in Scott's *Lady of the Lake*.

DOUGLAS, GAWIN or GAVIN (c.1474-1522). A Scottish poet, the third son of Archibald, fifth Earl of Angus. He was educated at St. Andrews for the church and was early appointed to Prestonkirk, near Dunbar. In 1501 he was made provost of St. Giles, Edinburgh. From the marriage of his nephew, the sixth Earl of Angus, to the widowed queen of James IV, Douglas expected rapid preferment; but the jealousy of the nobility and the Regent Albany was such that Douglas, who had, through the

influence of the Queen, obtained the bishopric of Dunkeld directly from the Pope (January, 1515), was tried before the Scottish peers, found guilty of conspiring against the privileges of the crown, and condemned to imprisonment. He was set at liberty in about a year and inducted into his bishopric. Owing to his nephew's ill-treatment of the Queen, who thereupon joined with the Regent against the Douglas, he was deprived of his bishopric (1520). He went to England to obtain the aid of Henry VIII, but accomplished nothing, and died suddenly of the plague in London. His poems belong mostly to his early life. They comprise two allegories, entitled *The Palace of Honour* and *King Hart*, and a translation of Vergil's *Aeneid* into Scottish verse. There is, besides, a minor poem on *Conscience*. To each book of the *Aeneid* is prefixed a description of Scottish scenery, and the translation, finished in 1513, is the first complete rendering of a long Latin classic into English. In his original poems Douglas carried on the tradition of Chaucer. His allegories are beautiful, and his landscapes surpass any others in our early poetry. His *Works*, edited, with a memoir, by Small, were published in four volumes (Edinburgh, 1874). Consult J. H. Millar, *Literary History of Scotland* (London, 1903), and *Cambridge History of English Literature*, vol. ii (Cambridge and New York, 1907-13).

DOUGLAS, GEORGE. The temporary keeper of Lochleven Castle, in Scott's *Abbot*. He falls in love with Mary, Queen of Scots, helps her to escape, and is killed in the battle of Langside.

DOUGLAS, GEORGE (1825-94). A Canadian clergyman, born at Ashkirk, Scotland. As a boy, he was brought by his parents to Montreal, Canada, was apprenticed to a blacksmith, and later was clerk in a bookstore. He started to study medicine, but, having decided to be a Methodist minister, he went to England in 1849 to finish his training at the Wesleyan Theological College. Thence he was at once sent as a missionary to the Bahamas. Ordained to the ministry in 1850, he went to Bermuda, where he remained a year and a half and contracted an illness from which he never fully recovered. During the nine years following his return to Canada he filled pastorates in Kingston, Toronto, and Hamilton. His preaching was remarkable for an ornate and stately eloquence which gave him rank as one of the greatest pulpit orators of Canada. He filled the highest administrative offices of his church, and was for seven years president of the Wesleyan Theological College at Montreal. In 1869 McGill University conferred upon him the degree of LL.D.

DOUGLAS, GEORGE WILLIAM (1850-). An American clergyman, born in New York City. He graduated from Trinity College (Conn.) in 1871 and from General Theological Seminary and studied also at Oxford and Bonn, and, being ordained a priest in the Protestant Episcopal church (1878), thereafter until 1898 had charges in New York, Washington, and New Haven. He was select preacher for Grace Church, New York, and an instructor in the Training School for Deaconesses from 1898 to 1904, when he became examining chaplain for the diocese of New York and senior canon of the cathedral of St. John the Divine. His writings include: *Hints to Sunday School*

Teachers (1883); *Prayers for Children* (1884); *Sermons Preached in St. John's Church, Washington* (1893); *The Many-Sided Roosevelt* (1907); *Essays in Appreciation* (1912; enlarged, 1913).

DOUGLAS, SIR HOWARD, BART. (1776-1861), son of Admiral Sir Charles Douglas. An English general and author of important military and naval treatises, born at Gosport. After serving in Spain and Portugal he was appointed Governor of New Brunswick (1823-31) and Lord High Commissioner of the Ionian Islands (1835-40) and elected member of Parliament for Liverpool (1842-47). He was made general in the army in 1851, and colonel of the Fifteenth Infantry Regiment. He died at Tunbridge Wells. His best-known work is *Military Bridges and the Passage of Rivers* (London, 1816), an essay which, it is claimed, suggested the suspension bridge. His treatise on *Naval Gunnery* (1820) was regarded as authoritative in several countries.

DOUGLAS, JAMES. See MORTON, JAMES DOUGLAS, fourth EARL OF.

DOUGLAS, SIR JAMES (1803-77). A Canadian administrator and the chief founder of British Columbia. He was born in Demerara, British Guiana, but in early youth was taken to Scotland, where he was educated in a private school at Lanark. When 16 years old he came to Upper Canada and was employed at Fort William by the Northwest Company, the rival of the Hudson's Bay Company in the fur trade. Upon their meeting in 1821 he was sent into the Hudson's Bay Company's territory west of the Rocky Mountains and known as the Columbia Department. In 1824 he was transferred to New Caledonia, the nucleus of British Columbia. In that department his qualifications as accountant, explorer, trader, and organizer, enhanced by his dependable character, gained the confidence of the company and made him especially valuable in the establishment and oversight of new posts. In 1830 he was sent to Fort Vancouver, Oregon Territory, where, as coadjutor to the chief factor, John M. Douglas, he shared the weighty responsibility of carrying out a policy of expansion which promised dramatic results. During 1830-46 the company's forts were built northward towards Alaska, southward towards California, and also into the interior of Oregon; but the hopes founded on these successes were not realized. In 1842 Douglas, who foresaw that the incoming tide of settlement would destroy the fur monopoly in the region immediately tributary to Fort Vancouver, decided that an Indian village situated where Victoria, B. C., now stands, was the best northerly site for the western headquarters, and in 1843 he built a fort there, the nucleus of the present city. The Treaty of 1846 finally broke the company's monopoly in United States territory below lat. 49° N. (See NORTHWEST BOUNDARY DISPUTE; OREGON, *History*.) In 1846 Douglas was appointed senior officer of the Western Department, and in 1851 he became Governor of Vancouver Island, which had been acquired by the company and was afterward created a crown colony. For seven years he combined the functions of civil ruler and chief factor of the company, whose long discipline of its officers and servants, as well as of the Indian tribes, had instilled habits of order and justice. In 1858 the rush of miners into the country con-

sequent to the discovery of gold severely tested his administrative skill; but in this Douglas, though competent, was assisted by Sir Matthew Baillie Begbie (1819-94), a judge whose fearless vigilance and impartial decisions were thoroughly effective in preserving order. In 1859, after the exciting episode of the military occupation of the island of San Juan by the American General Harney, the mingled firmness and forbearance of Douglas made possible the subsequent joint occupation of the island by American and British troops. (See SAN JUAN BOUNDARY DISPUTE.) In 1856 representative government was established in Vancouver Island, and in 1858 the crown colony of British Columbia was created. Douglas held the governorship of the two colonies concurrently until 1863. His vigorous promotion of road building was essential to the progress of British Columbia. He retired from public life in 1864. Although in full vigor of mind and body, he relinquished office chiefly because of his lack of training for, and intelligent sympathy with, the complicated tasks of representative government. His official experience had been that of a benevolent autocrat. In 1863 he was knighted. After his retirement he made a trip to Europe and returned to Victoria, where he died. Consult Begg, *History of British Columbia* (1894), and Coats and Gosnell, *Sir James Douglas* (1908), in the "Makers of Canada Series."

DOUGLAS, JAMES (1837-). An American mining engineer and metallurgist. He was born in Quebec and was educated in Edinburgh and at Queen's University, Kingston, where he graduated in 1858. He studied theology and was ordained to the Presbyterian ministry, but after some years resigned. For a time he was professor of chemistry in Morrin College, Quebec, and in 1869 and subsequently he was president of the Literary and Historical Society of that city. In 1875 he went to Phoenixville, Pa., to take charge of copper works. He was remarkably successful in mining and railway enterprises and became president and business manager of a number of mining corporations, besides serving as president of several railways in Mexico. He was a delegate from the United States to the Mining Congress at Paris in 1900, and he was president of the American Institute of Mining Engineers in 1899-1900. He published: *Memoir of J. S. Hunt, F.R.S.* (1898); *Untechnical Addresses on Technical Subjects* (1905); *Old France in the New World* (1905); *The Influence of the Railroads of the United States and Canada on the Mineral Industry* (1909); *Journals and Reminiscences of James Douglas, M.D.* (1910).

DOUGLAS, JOHN (1721-1807). An English author and divine, the son of a shopkeeper at Pittenweem, Fifeshire, Scotland, educated at Dunbar and Oxford, and ordained deacon in 1744. As an army chaplain he was present at the battle of Fontenoy (1745). Two years later he was ordained priest. Preferment after preferment followed until in 1791 he became Bishop of Salisbury. He died May 18, 1807. Douglas only occasionally resided on his livings. He generally spent the winter in London and the summer at fashionable watering places, in the society of the Earl of Bath, who was his great patron. Among his writings, mostly controversial, are: *Vindication of Milton from the Charge of Plagiarism, Adduced by Lauder* (1750); *A Letter on the Criterion of Miracles*

(1752), a reply to Hume; and many political pamphlets. He also edited the journals of Captain Cook. His *Miscellaneous Works*, edited and with a *Life* by Macdonald, were published in 1820).

DOUGLAS, SIR JOHN SHOLTO. See QUEENSBERRY, MARQUIS OF.

DOUGLAS, SIR ROBERT KENNAWAY (1838–1913). An English Sinologue, born at Larkbear House, Devon. He was attached to the English Legation at Peking, and subsequently taught Chinese in King's College, became governor of Dulwich College and keeper of Oriental books and manuscripts in the British Museum, and retired in 1907. He wrote articles on China and the East in the *Encyclopædia Britannica*, a catalogue of the Chinese books and manuscripts in the British Museum (1877), and *Two Lectures on the Language and Literature of China* (1875); *The Life of Jenghiz Khan* (1877); *Confucianism and Taoism* (1879); *China* (1882); *The Life of Li Hung-chang* (1895); *China* (1906); *Europe and the Far East* (1904; 1913).

DOUGLAS, ROBERT LANGTON (1864–). A well-known English art critic, lecturer, and author. He was educated at New College, Oxford, was for years a University Extension lecturer, and for a time was in holy orders in the Church of England. From 1895 to 1900 he resided in Italy, and from 1900 to 1902 was professor of modern history at the University of Adelaide (Australia). He also lectured on art at the Royal Institution and the Society of Arts, was made dean of the faculty of arts in 1901, and contributed to many magazines and reviews. Known chiefly as an authority on Sienese art, his most important publications are: *Ira Angelico* (2d ed., 1902); *History of Siena* (1902); *Le Maioliche di Siena* (1904); a new edition of Crowe and Cavalcaselle's *History of Painting in Italy* (1903 et seq.); *Illustrated Catalogue of Pictures of Siena and Objects of Art* (Burlington Fine Arts Club, 1904). He was elected a fellow of the Accademia di Belle Arti, Milan.

DOUGLAS, STEPHEN ARNOLD (1813–1861). An eminent American political leader. He was born in Brandon, Vt., April 23, 1813. He passed his boyhood in his native State and in western New York, went to Illinois in 1833, taught school and studied law for a year, was admitted to the bar in 1834, and began practice in Jacksonville. Within a year he was elected State's attorney for the most important judicial circuit in Illinois, and his rise thenceforward was rapid and brilliant. In 1836 he was elected to the Lower House of the State Legislature and in the following year was made register of the Federal land office at Springfield. In 1838 he was an unsuccessful Democratic candidate for Congress, but in January, 1841, was appointed Secretary of State of Illinois, which position, however, he resigned within a month to take a seat on the bench of the Supreme Court of the State. After two years he resigned this position also, and thereafter served in Congress, first as a representative (from 1843 to 1847) and then as a senator, from 1847 until his death. In figure he was below the middle height, but his frame was vigorous and his manner impressive. "Little Giant," says Schouler, "he was presently called: for, being both able and adroit in policy and full of resources, he gave the image of power under

close compression." As chairman of the Committee on Territories, first in the House and then in the Senate, his position was peculiarly important. He favored the annexation of Texas and the Mexican War, opposed the Wilmot Proviso (q.v.), defended the Compromise measures of 1850, and upheld the extreme demands for the Oregon Territory. He became especially conspicuous, however, through his proposal and advocacy of the doctrine of "popular sovereignty," or "squatter sovereignty," which denied the power of the Federal government to legislate on slavery within the Territories and recognized the right of the people of each Territory to legislate upon the subject for themselves. This doctrine, first announced by Lewis Cass (q.v.), in December, 1847, was definitely formulated by Douglas in 1854, when he presented the Kansas-Nebraska Bill, which precipitated anew the struggle over the extension of slavery in the national Territories. The bill, in its first draft, also in precise terms announced the doctrine that the Missouri Compromise had been superseded by the Compromise of 1850, and, although nothing in the statutes warranted such an assertion, its political effect was great and immediate. The passage of the act brought upon Douglas much harsh criticism throughout the North, and indicated, on the other hand, the increasing strength of the upholders of slavery. (See KANSAS-NEBRASKA BILL.) Douglas now became, more than ever, a national force. Nevertheless, in 1856, as in 1852, he failed to secure the presidential nomination. In 1857 he broke with President Buchanan and the "administration" Democrats, thereby losing much of his prestige in the South. His campaign in 1858 for the election of the State I . . . which was to name his successor . . . led to the famous debates with Lincoln, in which the problems of slavery were thoroughly discussed and the foundation laid for the national reputation of his opponent. Douglas secured a reelection to the Senate, but his position had become so altered through his opposition to the recognition of the Lecompton Constitution in Kansas and by reason of his "Freeport Doctrine" (see FREEPORT, Ill.), that in 1860 he was unacceptable to Southern Democrats as a presidential candidate. However, the Northern Democrats would not support for the presidency a man holding the prevailing Southern views on slavery. This brought about a sectional division of the nominating convention and the subsequent nomination of Douglas for the presidency by his Northern followers assembled in Baltimore. In the ensuing election he received only 12 electoral votes, but his popular vote was next to that of Lincoln. His influence continued to be strong, and his hearty support of Lincoln's administration upon the outbreak of the Civil War was of powerful effect in the defense of the Union. Consult: *Life of Stephen A. Douglas*, by J. W. Sheahan (New York, 1860); vols. i and ii of Rhodes's *History of the United States from the Compromise of 1850* (7 vols., New York, 1892–1906); *Stephen Arnold Douglas* (Boston, 1902), by W. G. Brown, in the "Riverside Biographical Series"; E. C. Carr, *Stephen A. Douglas* (Chicago, 1909).

DOUGLAS, THOMAS. See SELKIRK, THOMAS
DOUGLAS, fifth EARL OF.

DOUGLAS, SIR WILLIAM FETTES (1822–91). A Scottish figure and landscape painter, born

in Edinburgh. He was a pupil of Lauder, but in the main was self-taught. After exhibiting portraits in the Royal Scottish Academy he gained a reputation with his pictures representing occult and romantic subjects, such as "Bibliomania" (1852, National Gallery, London); "The Rosicrucian"; "The Alchemist" (1855, South Kensington Museum); "Visit to the False Astrologer" (1860). These compositions are simple and dignified, with a gleaming, luminous tone, reminiscent of the old masters. He was an ardent antiquarian and introduced the objects of his collection into his pictures. After 1870 he started to paint landscapes which include "Stonehaven" and the "Bay of Lunan," in the Edinburgh Gallery, and towards the close of his life he produced some delicate water colors. Douglas was curator of the National Gallery of Scotland, and president of the Royal Scottish Academy for many years. Consult *Photogravures from the Works of Sir W. F. Douglas, with a Critical Sketch by J. M. Grey* (1885).

DOUGLAS, WILLIAM LEWIS (1845-). An American manufacturer and politician, born in Plymouth, Mass., and educated in the public schools. He began work at the age of seven in a shoe factory and in 1865 went to Colorado, returning to Brockton, Mass., in 1876 and establishing a shoe factory. From this beginning he had built up by 1914 a business having six factories with a combined capacity of more than 20,000 pairs of shoes daily, the source of supply of his 78 retail stores. He was a member of the Massachusetts Legislature from 1883 to 1887 and in 1891 was elected mayor of Brockton. In 1904 he was elected Governor of Massachusetts on the Democratic ticket.

DOUGLAS CITY. A town on Douglas Island, opposite Juneau, Alaska, mainly occupied by workmen of the adjacent Treadwell gold mines. The native village, or quarter, has a government school for the training of the Tlinkit children. Pop., 1910, 1722.

DOUGLAS FIR. See SPRUCE.

DOUGLASS, DAVID BATES (1790-1849). An American civil and military engineer, born at Pompton, N. J. He graduated at Yale in 1813, entered the army, and rendered effective service in the defense of Fort Erie against the British. In 1819-20 he was assistant professor of natural and experimental philosophy at West Point. Subsequently he held the professorship of mathematics and from 1823 that of civil and military engineering, which he resigned in 1831 to become chief engineer of the Morris Canal Company. His most important engineering work for New York City was the making of surveys and plans for the Croton Aqueduct and for Greenwood Cemetery. He was president of Kenyon College from 1841 to 1844 and was made professor of mathematics at Hobart College in 1848.

DOUGLASS, FREDERICK (1817-95). An American antislavery orator and journalist, born at Tuckahoe, near Easton, Md. His father was a white man, his mother a negro slave, and he was reared as a slave on the plantation of Col. Edward Lloyd until he was 10 years old, when he was transferred to a relative of his owner in Baltimore. There he worked in a shipyard and taught himself to read and write. In 1838 he escaped from slavery under the disguise of a sailor and changed his name from Frederick Augustus Washington Bailey to Fred-

erick Douglass. He proceeded first to New York City and then to New Bedford, Mass., where he married a negro woman, and where for several years he was employed as a day laborer. In 1841 he attended an antislavery convention at Nantucket and spoke with such power and eloquence that the Massachusetts Antislavery Society sent him out as a lecturer under its auspices. He met with so much success that an invitation to lecture in Great Britain was extended to him and was accepted. In 1845 he published his autobiography and went to England, where he remained two years, and where a contribution of £150 was raised to buy his freedom in regular form. On his return to America in 1847 he settled at Rochester, N. Y., and began to publish a weekly Abolition newspaper, which was continued until 1860, being called the *North Star* until 1850, when it was renamed *Frederick Douglass's Paper*. In 1855 he rewrote his autobiography, which was republished in 1882 as the *Life and Times of Frederick Douglass*. During the Civil War he was among the first to suggest the employment of negro troops by the United States government. In 1871 he was secretary to the Santo Domingo Commission; in 1872 a presidential elector for the State of New York; in 1877-81 United States Marshal for the District of Columbia; in 1881-86 recorder of deeds in the District; and in 1889-91 Minister to Haiti. Consult lives by Holland (New York, 1891) and by Chesnut (Boston, 1899). Consult Booker T. Washington, *Frederick Douglass* (Philadelphia, 1907).

DOUKHOBORS. See DUKHOBORTSKY.

DOULS, CAMILLE (1864-89). A French explorer, born at Rodez. He entered upon his tours of exploration in 1887, when he visited the region south of Morocco in the disguise of a Mussulman merchant. He was captured and imprisoned by one of the native tribes, but subsequently liberated, and succeeded in reaching Morocco. In 1888 he began another tour, intending to proceed through the Sahara as far as Timbuktu; but after penetrating for a considerable distance into the country he was assassinated by his two Tuareg guides. The results of his first voyage were published in the *Bulletin de la Société de Géographie* (1888), *Revue de Géographie* (1888), and in *Le Tour du Monde* (1888).

DOULTON, SIR HENRY (1820-97). An English potter, born in Vauxhall. He learned his profession in his father's factory at Lambeth, which he soon developed into the largest pottery works in the world, and it was chiefly he who effected the revival of "art pottery." The most noteworthy of his ware was the "sgraffito," which traced its origin to the agate or self-glazed stoneware of the latter part of the seventeenth century. He created a sensation at the South Kensington Exhibition in 1871, which was followed by further exhibits in Vienna and Paris. Branch factories were opened throughout England and in Paris, and the ware was introduced into the United States in the seventies by John Bennet, a former director of the Lambeth works. A school of art was conducted in conjunction with the undertaking, and distinctive features were introduced. Since the business was turned into a joint-stock company in 1899, the artistic value of its ware has declined. Consult Chaffers, *Pottery and Porcelain* (London, 1900), and Barber, *The Pottery and*

Porcelain of the United States (3d ed., New York, 1909).

DOUMER, dōm'mē', PAUL (1857-). A French statesman, born at Aurillac (Cantal). He became in 1885 chief assistant to Floquet, President of the Chamber of Deputies, and in 1888 and 1890 was elected as a Radical deputy. He was Minister of Finance in the Bourgeois cabinet (1895-96) and from 1896 to 1902 was Governor-General of French Indo-China, where he carried through important public works and the political and financial unification of the French possessions. Reëntering the Lower House in 1902, he became head of the Budget Commission, and, in 1905, President of the Chamber. In 1906 he was the candidate of the moderate and reactionary parties for President of the Republic to succeed Emile Loubet, but received only 371 votes to 449 for Armand Fallières (January 17). In 1909 he was again head of the Budget Commission. In 1910 he failed of reelection to the Chamber. He published *L'Indo-Chine française* (1904) and *Livre de mes fils* (1905).

DOUMERGUE, dōm'mērg', EMILE (1844-). A French Protestant church historian, born in Nîmes, and educated at Geneva, Montauban, Erlangen, and Berlin. In 1871-80 he edited the periodical called *Le Christianisme au XIXe Siècle*, and he became professor of Church history and dean of the Protestant theological faculty at Montauban. His great work is his biography of Calvin, entitled *Jean Calvin: les hommes et les choses de son temps* (5 vols.: vol. i, 1899; vol. iv, 1910), the result of a lifelong study of the subject, upon which he wrote many minor volumes, notably *Iconographie calvinienne* (1909).

DOUMERGUE, GASTON (1863-). A French statesman, born at Algues-Vives (Gard). He studied law, served as an advocate at Nîmes in 1885-90, and was colonial magistrate in Cochinchina in 1888 and in Algiers in 1890-93. As a member of the Radical-Socialist party, he was elected a deputy from Nîmes and reëlected in 1898, 1902, and 1906, and he was Secretary in 1895-96 and Vice President in 1905-06 of the Chamber. He served as Minister of the Colonies (1902-05) in the Combes cabinet, as Minister of Commerce (1906-08) in the Sarrien and Clémenceau cabinets, and as Minister of Public Instruction (1908-10) in the Clémenceau and the first Briand cabinets. Later Doumergue became a member of the French Senate, and in December, 1913, he was called on to form a new ministry, in which he held the portfolio of Foreign Affairs as well as the premiership. In June, 1914, he resigned, with his cabinet.

DOUMIC, dōm'mēk', RENÉ (1860-). A French literary and dramatic critic, born at Paris and educated at the Lycée Condorcet and the Ecole Normale Supérieure. Besides serving as professor at Stanislas College, he lectured in Canada and at Harvard University in 1898. He became especially known for his criticisms published in the leading French journals. He became Chevalier of the Legion of Honor and in 1909 was elected a member of the Academy. His writings include: *De Scribe à Ibsen* (1893); *Ecrivains d'aujourd'hui* (1894); *Etudes sur la littérature française* (5 vols., 1896-1905); *Les jeunes* (1896); *Essais sur le théâtre contemporain* (1897); *Hommes et idées du XIXe siècle* (1903); *Les*

lettres d'Elvire à Lamartine (1905); *Le théâtre nouveau* (1908); *George Sand* (1909); *Lamartine* (1912); *Histoire de la littérature française* (30th ed., 1913).

DOUR, dōr. A town in the Province of Hainaut, 9 miles S. of Mons (Map: Belgium, B 4). Coal and iron mines and stone quarries are worked in the vicinity, and some coke is produced. There is also a thread mill and a rope factory. Pop., 1900, 11,425; 1910, 12,670.

DOURINE, dōr'ēn. Dourine, or maladie du coït, is a specific infectious disease of the horse and ass, transmitted from animal to animal by the act of copulation and caused by a protozoan parasite, the *Trypanosoma equiperdum*. The disease is characterized by an irregular incubation period, the confinement of the first symptoms to the genital tract, the chronic course which it runs, and by finally producing complete paralysis of the posterior extremities, with a fatal termination in from six months to two years. It occurs in Asia, Africa, and continental Europe, and has been introduced into the United States several times with imported stallions. At the present time (1914) its eradication from eastern Montana and the Dakotas, in which it is known still to occur, is under way by the United States Department of Agriculture.

In mild cases an apparent recovery may follow, and through such animals the disease is disseminated. It is now readily detected by the blood test known as complement fixation. Treatment of the disease has proved unsatisfactory. It should be stamped out by the slaughter or castration of every horse or mare that has had sexual congress with a diseased animal or which gives a positive blood test.

Consult: Hutyra and Marek, *Pathology and Therapeutics of the Diseases of Domestic Animals*, vol. i (London, 1912); E. W. Hoare, *A System of Veterinary Medicine*, vol. i (2d ed., New York, 1906); J. R. Mohler, "Dourine of Horses: Its Cause and Suppression," in *United States Department of Agriculture, Bureau of Animal Industry, Bulletin 142* (Washington, D. C.).

DOURO, dō'e-rō. See DUERO.

DOUROUCOULI, dōr'ōō-kōō'lē (South American Indian). A small monkey of Brazil of the genus *Nyctipithecus* or *Aotus*, sleeping by day but active and fierce at night in pursuit of birds and insects. The body is about 9 inches long, the tail 14; fur soft and grayish white, with a brown stripe down the back. The head is round, and the eyes are extremely large and prominent. Douroucoulis look more like cats than monkeys and sit up like dogs. Several species are known, all confined to South America, where they represent the lemurs of the Old World. Consult Bates, *The Naturalist on the River Amazon* (London, 1863), and Elliot, *Review of the Primates*, vol. ii (New York, 1913).

DOURRA, dōr'rā. See SORGHUM, paragraph *Nonsaccharine*.

DOUSA, JANUS (JAN VAN DER DOES) (1545-1604). A Dutch statesman, scholar, and historian, born in Noordwijk, and educated at Delft, Louvain, Douai, and Paris. In 1572 he was sent by the Estates of Holland on an embassy to England; and in 1574 was Governor of Leyden when it was besieged by the Spaniards. When the University of Leyden was founded, he was appointed first curator, and the

success of the university was largely due to his wisdom. In 1584 and 1585 he was again in England trying to interest Queen Elizabeth in the cause of the States. In 1591 he was appointed a member of the Sovereign Council. His principal work was the *Annals of Holland* (*Annales Rerum*), a Latin hexameter history, covering the period 898-1218 A.D. He wrote a commentary on Horace and criticized Catullus, Tibullus, Petronius, etc.

DOUVILLE, döo'vél', JEAN BAPTISTE (1794-c.1835). A French traveler, born at Hambye, Manche, France. He traveled extensively in Asia and South America, and in 1832 published in three volumes *Voyage au Congo et dans l'intérieur de l'Afrique équinoxiale*, describing his discoveries in Central Africa. For this he was honored with the gold medal of the Société de Géographie de Paris and with honorary membership in the Royal Geographical Society of London. Later, however, his work was shown to be a fabrication based on early Portuguese discoveries.

DOUW, dou, GERARD. See DOU, GERARD.

DOUZETTE, döo-tsét'te, LOUIS (1834-). A German landscape painter. He was born at Triebsees, Pomerania, and studied with Eschke at Berlin. His specialty was moonlight painting, in which genre he excelled. Among his best works are "Moonlight Night in Winter" (1865); "Swedish Coast by Moonlight" (1866); "Moonlight on the Gulf of Venice" (1876, Melbourne); "Moonlight on the Fjord" (1883, Dresden Gallery); "Harbor of Lübeck by Moonlight" (1891); "Old Prerow on the Dars" (Berlin Gallery), one of many paintings of the German beech and oak forests. He was strongly influenced by the Barbizon painters and also by the Dutch, especially Ruysdael. Douzette received the gold medal at the Berlin Art Exhibition of 1886.

DOVE (Icel. *dúfa*, Ger. *Taube*, Dutch *duif*, Goth. *dūfō*, perhaps connected with Ir. *dub*, black, or possibly with AS. *dyfan*, to dip, from *dāfan*, to dive). A pigeon. No scientific distinction separates pigeons from doves, but the latter word is attached usually to the smaller forms of this group, such as the turtle, ring, ground, and scaled doves. (See Plate of PIGEONS.) The turtle doves are small, graceful, modestly dressed representatives of their kind, erroneously considered as the type of gentleness. The common European species (*Turtur*, or *Streptopelia, communis*) is migratory, and seems to be increasing. Another of the many Old World species, abundant in Asia Minor and eastward, is regarded as the "turtle" of Scripture. In the United States the bird frequently called turtle or mourning dove is *Zenaidura macroura carolinensis*, whose plaintive, throbbing refrain in early summer is familiar throughout the whole land and makes its name, "mourning dove," seem very appropriate. It is migratory, but with the spread of civilization and consequent increasing certainty of food about barns, etc., it is coming to remain more and more in the northerly districts throughout the winter. The scaled doves (*Scardafella*) are small and beautiful species of semitropical America; and another group belonging to the warmer parts of America and of terrestrial habits are called ground doves. Doves' nests are very slight structures, and the eggs are white. An example (that of the American Zenaida dove) is shown on the Colored Plate of

EGGS OF WATER AND GAME BIRDS with the article Egg.

Symbolism of the Dove. The dove has taken a large place in legend, folklore, and poetic and religious symbolism. Proper names derived from the dove have always been used in the Orient as descriptive of loveliness and were especially applied to beautiful women. The name "Semiramis" is said to mean "mountain dove," and the bird became the ensign of her army. Mr. Charles De Kay relates in his *Bird Gods* (New York, 1898) how extensively the dove was woven into the pagan worship of ancient Europe, and its place in early Christian art and religious symbolism is prominent. The people of northern Europe used to say that the

1. Dove as Holy Spirit; shedding blessings on the Saviour (Agnus Dei) at his baptism. Earliest example of the dove in Christian art. (From a bas-relief on the tomb of Junius Bassus, 359 A.D.)

2. Descent of the Holy Spirit as a dove upon Jesus; Heaven is represented as a circle studded with stars. (From a manuscript of the ninth century in the British Museum.)

3. The Holy Spirit as a dove speaking into the ear of Jesus at his baptism. (From a French manuscript, 1100 A.D., in the British Museum.)

4. The hand of God extending grace or a blessing as a dove from heaven. (From a Saxon manuscript in the British Museum.)

5. Dove standing on the altar. (From an Italian altar stone of the twelfth century.)

ringdove or cushat perched near the cross when Jesus was expiring and wailed its sorrow to alleviate his agony. To the Jews, from an immemorial time, it had been a type of innocence, and elsewhere it had been associated since the Olympian age with the higher idea of Venus as a symbol of natural human affection—the love that goes with, or proceeds from, purity and simplicity of heart. It had a part in marriage scenes and was naturally introduced by early painters into pictures of the Madonna and

Child and of female saints. These qualities, combined with their mournful notes, made doves equally appropriate to moods of sorrow, and they were a part of the furniture of most pagan

6. Dove typifying grace of the Holy Spirit descending upon a Christian in baptism. (From a painting, "Baptism of Verrocchio," in Florence.)

funerals. This passed on into Christian usage, and their likenesses, generally with an olive branch, were carved on thousands of tombs in the catacombs beneath Rome and elsewhere, emblematic of eternal peace. Various meanings seem to have been attached to these mortuary carvings, but the prevalent idea was that of

7. The Seven Gifts of the Spirit. This is a clear rendering of a theme which appears under many and sometimes confusing disguises. In this case it is notable that no nimbus or aureole is present, the circle of seven doves about the head of Jesus themselves forming a sort of aureole.

8. The dove "moving on the face of the waters" at the creation. (From a Saxon manuscript of the eleventh century, in the British Museum, where the Creator is represented above this figure holding compasses and scales.)

9. The Holy Spirit, in human form, holding a dove as a symbol. (From a sculpture of the sixteenth century, in the church of Verrières.)

portraying the departure of the soul from the body; and, later, artists often represented a white dove issuing from the lips of dying martyrs, as occurs in old pictures of Santa

Scholastica, the sister of St. Benedict, and of Santa Eulalia, the Spanish girl martyr who expired under tortures inflicted by the Emperor Diocletian. Hereby the human soul is represented as purified by suffering.

A very natural specialization of this idea was to make an approaching dove symbolize the divine soul or Holy Spirit, first in the general sense of heavenly messenger (i.e., inspirer), and next as the third person of the Trinity. In the former sense it is almost invariably placed in old pictures near certain saints who are supposed to have been particularly inspired, as St. Thomas Aquinas, St. Hilary, and others. Few, if any, early paintings of Pope (St.) Gregory the Great exist in which a dove is not resting upon his shoulder or hovering at his ear, whispering messages from on high. In this sense, but especially in that of signifying the Holy Ghost, the dove appears in most of the early representations of scenes in Christ's life—most frequently, perhaps, in pictures of his

10. An Italian representation of the Trinity, the Father and the Son in human form, and the Holy Spirit symbolized by a dove born from the breath of the Father and descending upon the Son. (Fourteenth century.)

baptism, literally rendering St. John's words (i. 32): "I saw the Spirit descending from heaven like a dove." The earliest instance of it in Christian art known to Mrs. Jameson is a bas-relief from a tomb dated 359 A.D. "The next instance," she cites, "is from a mosaic in the church of Santa Maria Maggiore, Rome, fifth century, and is the earliest representation of the Annunciation."

In the early pictures the dove's head is surrounded with a golden nimbus, which is frequently cruciform. Seven rays proceed from it, terminating in seven stars, signifying the "seven gifts of the Holy Spirit." In her *Symbols and Emblems of Christian Art* Louisa Twining gives varied examples of its treatment. Sometimes seven doves are attributes of the Virgin, occasionally within a *vesica piscis*. An English manuscript poem of the fourteenth century is illustrated by a series of scrolls inscribed: "Ye gyfte of Wisdome; Ye gyfte of pite; Ye gyfte of Strengthe; Ye gyfte of counsaill; Ye gyfte of Understandinge; Ye gyfte of conynge; Ye gyfte of diiede [a misprint for *dreede*, meaning dread,

fear].” Around the page are the lines below, in Old English text:

“In this desert wild and waste,
Seven fowls are flying with flight,
That are seven gifts of the Holy Ghost,
That nowhere but in clean hearts will light
And dwell there if they find them chaste,
And give them ghostly strength and might
So big and bold that they then haste
To pray to God both day and night.”

A dove with six wings is a type of the Church of Christ. Sometimes the pyx is in the form of the dove, suspended above the altar, the covers of fonts often bear the same image, and it is common as a symbolic decoration of baptisteries. Twelve doves represented the Twelve Apostles, and the bird is the emblem of any believer whatever.

The dove belongs to various legends more or less remote from the present line of thought. Thus, the emblem of St. Remigius is a dove with an oil cruse in its beak, “recalling that at the anointing of King Clovis a cruse of oil was brought from heaven by a dove at the prayer of this saint.” In other cases it represents a visual benediction descending upon a cross or upon the sacred monogram. Thus, the significance of the bird came to be so broad as to mean simply *Christian*.

DOVE. The dove is by the common law a wild animal (*feræ naturæ*), and, as such, not the subject of larceny, unless at the time of the taking in the custody of the person asserting ownership. An escaped pigeon is, like other wild things, common property; but if it be domesticated, or if found in a dovecot, it partakes of the status of domestic animals and is protected like other personal property. The right of erecting or keeping dovecots was in England, as well as in Scotland, in Normandy, and elsewhere, an exclusive privilege of the feudal lords and was rigorously protected by law, but such exceptional privileges have long been abolished. See *FERÆ NATURÆ*.

DOVE, dō've, ALFRED (1844–). A German historian. He was born in Berlin, a son of Heinrich Wilhelm Dove (q.v.). After studying medicine and the physical sciences at Heidelberg and Berlin (1861–66), he became a journalist and was successively the editor of the *Grenzboten* (1870) and of the publication *Im Neuen Reich*. During the period 1874–91 he was professor of history at Breslau (1874–84) and Bonn (1884–91). Returning to his journalistic activity in the latter year, he became for a time editor of the *Allgemeine Zeitung* in Munich. He published the posthumous manuscripts of Von Ranke, completing both the *Weltgeschichte* and the editing of the *Sämtliche Werke* of that celebrated author in 1890, after an arduous labor of four years. Among his own publications may be mentioned *Deutsche Geschichte im Zeitalter Friedrichs des Grossen und Joseph II.* In 1891 he edited the last volumes of Bismarck's parliamentary speeches.

DOVE, HEINRICH WILHELM (1803–79). A German physicist and meteorologist, born at Liegnitz, in Silesia. He studied at Breslau and Berlin. He was successively privatdocent and assistant professor of natural philosophy in Königsberg. He was transferred to the University of Berlin in 1829 and in 1837 was elected to a seat in the Academy of Sciences. His writings, which are very numerous, are to be found for the most part in the memoirs of that

academy and in Poggendorff's *Annalen*. His works include researches dealing with meteorology, climatology, induced electricity, and circularly polarized light. Among his works may be mentioned: *Ueber Mass und Messen* (1835), a treatise on the art of measuring, and the origin and comparison of the metrical standards of different nations; *Meteorologische Untersuchungen* (1837); *Ueber die nicht periodischen Aenderungen der Temperaturvertheilung auf der Oberfläche der Erde* (1840–47); *Untersuchungen im Gebeit der Inductionselectricität* (1843). In his capacity of director of the Royal Observatory he published annually an account of his labors and observations. The treatise on the *Distribution of Heat on the Surface of the Globe*, which was published in 1853 by the British Association, is also a work of importance. In this work he enters fully into the causes of periodic variations of temperature at different parts of the globe and lays down in admirable charts the monthly and annual isothermal and isabnormal lines, thus tracing the variations in form and position of the different isothermals throughout the year. *Das Gesetz der Stürme* (4th ed., 1874) has also been translated ('The Law of Storms'). Other works are: *Ueber Electricität* (1848); *Optische Studien* (1859); *Eiszeit, Föhn und Sirocco* (1867); *Klimatologie von Norddeutschland* (1871).

DOVE, RICHARD WILHELM (1833–1907). A German jurist, son of Heinrich Wilhelm Dove. He was born in Berlin, studied both ecclesiastical and civil law at Berlin and Heidelberg, and was appointed professor successively in the universities of Tübingen, Kiel, and Göttingen. In 1873 he was nominated a member of the Prussian Court of Ecclesiastical Affairs. Most of his writings were published in the *Zeitschrift für Kirchenrecht*, a leading European organ of ecclesiastical law, which he established and began to edit in 1860.

DOVE FLOWER, or PLANT. See *HOLY SPIRIT PLANT*.

DOVEKIE (probably from *dove* + diminutive *-kie*). The little auk (*Alle alle*), sea dove, or rotge, an Arctic sea bird (see *AUK*), which regularly appears in winter on the coasts of Norway, northern Scotland, and America as far south as Maine, where it is called pine knot. Occasionally it is driven farther south or inland. It is about 8 inches long, black and white in color, has a bill like a partridge, and flies and dives with extreme swiftness and dexterity. It feeds upon small fish, crustacea, worms, etc., and frequently great numbers are found dead on our coasts, starved or crushed by the icy gales. In summer it becomes sooty brown and resorts in countless hordes to the most northerly islands and headlands to breed—especially to Spitzbergen, where each pair hide their single white egg deep in the recesses of the loose rocks of the coast mountains or, failing that cover, on some ledge. The same name is given by sailors to the black guillemot (*Cephus grylle*).

DOVE PLANT. See *HOLY SPIRIT PLANT*.

DOVER. A parliamentary and municipal borough of Kent, England, on the Strait of Dover, at the mouth of the Dour, 76 miles by rail east-southeast of London (Map: England, H 5). It is the headquarters of the southeastern district of the British army and is not only a charmingly situated watering place, but, being the nearest point of the English coast to France, 21 miles distant, is a seaport of importance.

Among the noteworthy buildings in Dover, aside from its fortifications, are the two ancient churches of St. Mary and Old St. James; the Maison Dieu, founded in the thirteenth century as a pilgrims' hospital, but now used for municipal purposes as a part of the new town hall; and the remains of St. Martin's Priory, incorporated as a part of Dover College. The fortifications are very extensive. On the chalk cliffs to the east of the town rises Dover Castle, founded by the Romans and fortified and enlarged by the Saxons and Normans. It contains the remains of a Roman pharos and an old fortress church, a unique specimen of Roman-British architecture. To the north of the castle is Fort Burgoyne, a drop redoubt, the north centre bastion and citadel. On these heights are large barracks and the ruins of another pharos and of a circular church of the Knights Templars.

Very extensive harbor improvements, begun in 1893, were carried out in subsequent years. On the west the Admiralty Pier (about 2000 feet, completed 1871) was extended in a southeasterly direction for 2000 feet; on the south an isolated breakwater was erected, extending to within a few hundred feet of another breakwater (3320 feet) built out from the mainland to form the eastern limit of the harbor. Within the harbor thus practically inclosed is still another pier (Prince of Wales, completed 1902), running nearly parallel with the old Admiralty Pier and forming with the latter a sheltered area of 75 acres. The entire harbor has an area of 610 acres, of which over half has a minimum depth of 30 feet at low tide. For harbor defense three powerful forts were begun in 1909.

The corporation owns its water supply and owns and operates electric street railways. It maintains public baths, markets, and a technical school. Dover returns one member to Parliament. The United States is represented by a consular agent. The town has a miscellaneous maritime trade and an enormous passenger traffic to and from the Continent. The total tonnage entered and cleared in 1912, excluding coastwise vessels, was 4,497,861; combined imports and exports amounted to £15,759,169. Pop., 1901, 41,794; 1911, 43,645. In Roman days, Dover was known as Dubris; the Normans called it Dovore; the French, Douvres. Fortified and walled by William the Conqueror, during whose reign it was nearly burned down, noted as the place of King John's submission to the Pope, besieged by the French, held during the Civil War by the Parliamentarians, threatened by the first Napoleon, and long celebrated as the headquarters of the lord wardens of the Cinque Ports, Dover holds a distinguished place in English history. Consult *Steuart, History of Dover*, with a bibliography (London, 1899).

DOVER. The capital of the State of Delaware, and the county seat of Kent County, 48 miles by rail south of Wilmington: situated on St. Jones River, and on the Philadelphia, Baltimore, and Washington Railroad (Map: Delaware, J 2). It is regularly built on elevated ground. The Wilmington Conference Academy (Methodist Episcopal) and the State college for colored students, an agricultural and manual training school, are located here. The public buildings include the State House, which contains a State library of 80,000 volumes, the county courthouse, new State armory, and the post office. There are monuments to persons distinguished in Revolutionary history. The city,

situated in a noted fruit-growing region, has several fruit-canning and canning works. There are also planing and saw mills, foundry and machine shops, sash and door, paint, and basket and crate factories, flour mills, and an electrical-specialty factory. Dover was laid out in 1717, became the capital of Delaware in 1777, and was incorporated as a town in 1829. The government is vested in a mayor and eight councilmen, and the water works and electric plant are owned by the city. Pop., 1880, 3329; 1900, 3329; 1910, 3720.

DOVER. A city and the county seat of Strafford Co., N. H., 11 miles by rail northwest of Portsmouth, at the head of minor navigation on the Cocheco River, and on the Boston and Maine Railroad (Map: New Hampshire, J 7). The river here has a fall of over 30 feet, furnishing excellent water power. Dover is an important shipping port. The chief industries include the manufacture of cotton and woolen goods, machinery, castings, belting, bricks, printing presses, cutlery, lumber in various products, boots and shoes, etc.—industries which in 1912 employed about 4200 persons, represented a capital investment of about \$6,000,000, and produced an output valued at nearly \$7,000,000. Dover has a public library, a fine city hall and opera house, two hospitals, two children's homes, and a home for the aged. The city is governed by a mayor, elected annually, and a bicameral council, which controls the appointments to the subordinate municipal offices. The municipal water commission operates an efficient system of water works. First settled in 1623, and therefore the oldest city in the State, Dover was organized as a town in 1633, received its present name in 1639, and was chartered as a city in 1855. It was a frontier town throughout the seventeenth century and frequently suffered from Indian attacks, the most disastrous of which occurred on June 28, 1689, when 23 of the inhabitants were killed, 29 carried into captivity, and a number of houses destroyed. Pop., 1900, 13,207; 1910, 13,247; 1914 (U. S. est.), 13,264.

DOVER. A town in Morris Co., N. J., 39 miles by rail west by north of New York City, on the Rockaway River, the Morris Canal, and the Lackawanna and the Central of New Jersey railroads (Map: New Jersey, C 2). It has extensive ironworks, machine shops, stove, furnace, and range works, boiler and bridge works, rolling mills, drill works, knitting and silk mills, a large hosiery factory, and an overall factory. A government powder depot is located at Piccatinny, 5 miles from Dover. The town government, under a charter amended in 1875, is vested in a mayor, biennially elected, a recorder, aldermen, and councilmen, who constitute a unicameral municipal council. Dover was incorporated as a village in 1826 and in 1869 as a town. It has municipal water works. Pop., 1900, 5938; 1910, 7468.

DOVER. A town and the county seat of Stewart Co., Tenn., 67 miles (direct) west-northwest of Nashville, on the Cumberland River (Map: Tennessee, C 2). It is 1 mile from Fort Donelson and contains a national cemetery of 672 graves. Pop., 1914, about 600.

DOVER, STRAIT OF. A strait separating England from France and connecting the English Channel with the North Sea (Map: England, II 6). On the English coast its limits are defined by the promontories of Dungeness and South Foreland, and on the French coast it ex-

tends from Cape Gris-Nez to Calais. It is 20 to 27 miles wide and 1 to 20 fathoms deep. The Ridge Shoals near the middle of the strait are over 8 miles long and have a depth of 10 to 24 feet. Both the English and French shores are formed by chalk cliffs of corresponding strata, showing a former connection at this point. The strait has been carefully surveyed by engineers with a view to bridging or tunneling it. There is great opposition in England, on military grounds, against the construction of a tunnel. It is, perhaps, the most frequented maritime route in the world.

DOVER'S POWDER (named from Thomas Dover, an English physician of the eighteenth century, who first prepared it). An old preparation of powder of ipecacuanha 1 dram, opium in powder 1 dram, and sulphate of potash 1 ounce, the whole being thoroughly mixed. Sugar of milk is now substituted for the sulphate of potash, and occasionally saltpetre is added. The powder is used in domestic practice to induce vomiting to abort a "cold," as well as at the beginning of any attack of fever; but it should be used cautiously, on account of the opium it contains.

DOVE TICK. A blind tick (*Argas reflexus*), well known in Europe as a parasite of doves and some other birds. A closely related species is the Asiatic *Argas persicus*, which dwells in houses "and by its punctures produces convulsions in man, and it is said that even death has resulted from its sting." A third species, the pique (*Argas nigra*), is also distressing. See TICK.

D'OVIDIO, dō-vēd'yō, FRANCESCO (1849-). An Italian philologist and literary critic, after 1876 professor of romance philology at the University of Naples. His name is associated in Italy with that of Ascoli and D'Annunzio in the development of philology, science and in the critical study of literature from the historical standpoint. His scholarship, though not so intensive, has a very wide range.

DOW, GERARD. See DOU, GERARD.

DOW, LORENZO (1777-1834). An American preacher, noted for his eccentricities and zeal. He was born at Coventry, Conn., Oct. 6, 1777. His education was limited. In youth he joined the Methodists (1799), but left the official ministry under a conviction that he was called to be a missionary to the Roman Catholics of Ireland. His preaching in that country attracted crowds of people and brought him some persecution. He also visited England, introducing there the Methodist system of camp meetings. He returned to the United States, and repeated his visits to Ireland and England in 1805. He preached in many parts of the United States. His natural eloquence and his eccentricities of dress and speech attracted large audiences everywhere. He preached against Catholicism and especially against the Jesuits, whom he regarded as enemies of civil and religious liberty. His *Polemical Works* appeared in 1814. Among his other works are *The Life and Travels of Lorenzo Dow*, by Himself, in which are contained some singular providences of God (1804; 2d ed., 1806); *A Collection of Spiritual Songs Used at Campmeetings in the Great Revival in the United States of America* (1806); *The Stranger in Charleston; or, The Trial and Confession of Lorenzo Dow* (1822); *A Short Account of a Long Travel* (1823); and *The History of Cosmopolite* (1831). Consult his *Life and Writings* (New York, 1854). His wife,

Peggy Dow (1780-1820), was almost as eccentric as her husband. She published her journal, entitled *Vicissitudes in the Wilderness* (5th ed., 1833).

DOW, NEAL (1804-97). An American temperance reformer. He was born in Portland, Me., of Quaker parentage, and was educated at the Friends' Academy in New Bedford, Mass. He was twice mayor of Portland and in 1858-59 was a member of the State Legislature. In 1861 he was appointed colonel of the Thirtieth Maine Volunteers, which he commanded in General Butler's expedition to New Orleans. Promoted to the rank of brigadier general in 1862, he commanded the fortifications at the mouth of the Mississippi and later the Department of Florida. He was wounded and taken prisoner by the Confederates at Port Hudson in May, 1863, and was confined for eight months thereafter in Libby Prison. It was as a temperance reformer and orator, however, that he was best known. He was the author of the famous prohibition law enacted by the Maine Legislature in 1851, and traveled widely in the United States, Canada, and Great Britain, speaking on temperance questions and helping in the organization of societies for the furtherance of the reform. In 1880 he was the Prohibition candidate for President of the United States. Consult his *Reminiscences* (Portland, 1898).

DOWAGER (OF. *douagiere*, from *douage*, dower, from *douer*, *doer*, Fr. *douer*, It., Lat. *dotare* to endow, from Lat. *dos*, dower). A widow with a dower (q.v.). A title commonly applied only to the widows of persons of high rank. The queen dowager in Great Britain, as the widow of the king, enjoys most of the privileges which belonged to her as queen consort; but it is not high treason to conspire her death, because the succession to the crown is not thereby endangered.

DOWAGIAC, dō-wā'jāk. A city in Cass Co., Mich., 35 miles southwest of Kalamazoo, on the Michigan Central Railroad. It is in an excellent farming region, and has flour and lumber mills, a gas factory, and a canning establishment. The noteworthy features of the city are the Beckwith estate and the public library. Among other industries are manufactures of grain drills, stoves, gloves, bait, and furnaces. Pop., 1900, 4151; 1910, 5088.

DOWDEN, dou'den, EDWARD (1843-1913). A British scholar, critic, and educator, born in Cork, Ireland, and educated at Trinity College, Dublin, where his career as a student was brilliant, and where he became professor when in his twenty-fifth year. The chair of English literature in the University of Dublin he held up to the time of his death. *Shakespeare, His Mind and Art* (1875) at once established his reputation as a Shakespearean scholar. This work aimed to connect a study of the plays with a quest for the personality of the author of them and for the development of his intellect and character in their various stages of growth. It was followed by *Poems* (1876). In 1877 appeared the *Shakespeare Primer*, the best handbook of its type, owing to condensed information and critical concision. Next came *Studies in Literature* (1878), a volume of substantial and suggestive essays. His *Life of Shelley* (1886) is a notable work. A number of volumes of essays in literary criticism and several critical biographies followed, and in addition there was done much editorial work which bore, like everything that

came from Professor Dowden's pen, the stamp of a ripe scholarship and rare culture. His more important works, in addition to those already named, are: *Transcripts and Studies* (1888); *Introduction to Shakespeare* (1893); *New Studies in Literature* (1895); *A History of French Literature* (1877); *Robert Browning* (1904); *Michel de Montaigne* (1905); *Essays: Modern and Elizabethan* (1910). His collected *Poetical Works* (2 vols.) and *Letters* appeared in 1914. His editorial work includes: *Shakespeare's Sonnets*, *Southey's Correspondence with Caroline Bowles*, and the *Correspondence of Henry Taylor*; the poetical works of Shelley, Wordsworth, and Southey; and several of the plays of Shakespeare. In 1889 Professor Dowden was invited to lecture at Oxford; in 1893-96 he lectured at Trinity College, Cambridge; and in the last-named year at Princeton University, where his subject was *The French Revolution and English Literature*, and where he was honored with the degree of LL.D.

DOW'ELL, STEPHEN (1833-98). An English legal and historical writer. He was born on the Isle of Wight, graduated at Oxford in 1855, studied law at Lincoln's Inn, and in 1863 was appointed by Lord Palmerston Assistant Solicitor to the Board of Inland Revenue, an office which he held until 1896. In addition to numerous legal and historical tracts he was the author of several works on taxation, on which subject he was admittedly for many years one of the highest authorities in England. Among these works are: *The Income Tax Laws* (1874; 3d ed., 1890); *A Sketch of the History of Taxes in England* (1876); *A History of Taxation and Taxes in England, from the Earliest Times to the Present Day* (4 vols., 1885; 1888), the standard work on this subject.

DOWER (OF. *doaire*, Fr. *douaire*, Prov. *dotaire*, from ML. *dotarium*, dower, from Lat. *dos*, dower). The common-law right of the wife to a one-third interest for life in the real estate of her deceased husband. It is limited to freehold estates of inheritance, and the character of the holding must be such that the issue of the marriage, if any, might by possibility have inherited it. It extends, therefore, to all estates in fee simple of which the husband was seised at any time during coverture, and to all such fees tail as are limited to the issue of the husband by the wife in question. This interest in her husband's real estate attaches at the moment of marriage or of the subsequent acquisition by the husband of the property, and continues thereafter during the life of the wife, passing through three stages or forms. During the coverture and ownership of the property by the husband, she has an *inchoate* right of dower. This is a mere right or possibility of obtaining the property by surviving her husband. It is a right, however, which the courts will protect, as between her and her husband. He cannot at common law deprive her of it either by a conveyance to a third person or by last will and testament. After the death of the husband, and before she has been put into possession of the specific one-third of his realty which should be set apart for her, she has a right of action for the purpose of obtaining her dower. It is the duty of the husband's heirs, or purchasers, or other persons who may be in possession of the property, to set out or *assign* her one-third to her, and an action lies to compel the performance of that duty. After such assignment has been made, and she has been

given possession of the land, she acquires an interest or estate therein during her own life. Dower attaches to real property only and not to personal property. It is strongly favored by the common law. No act that the husband alone can do will bar it. If he sell real estate to which his wife's dower right is attached without having her unite in the transfer, the purchaser takes subject to such right. It is not necessary that the husband shall be actually in possession of the property in order to give the wife dower therein. The fact that he is seised, during the coverture, in fact or in law, of a beneficial estate of inheritance will be sufficient to support her claim to dower. The wife's common-law right of dower in her husband's real estate is of great antiquity and has analogies in most other systems of law. In our system it has passed through many stages. It is recognized as an inalienable property right in the coronation oath of Henry I (1100), though at that time and for many years afterward it might be varied by other forms of dower, which are now obsolete, as *dowment at the church door* and *dowment by the father's assent*. These enabled the husband, by a declaration which formed part of the marriage service, to confer on his wife a dower right to the whole, or the half, or any other proportion of his lands which should be acceptable to her, and which on his death she might accept in lieu of the one-third accorded to her by the common law. If at that time she rejected the formal endowment, she was entitled to fall back on her common-law dower. The declaration of the bridegroom in our marriage service, "with all my worldly goods I thee endow," which is now of no legal effect whatever, is a curious survival of this ancient practice.

At a much later period, when the practice of conveying lands in trust, or to the use of others, had become common in England, the common-law right of dower was *displaced* in abeyance, being replaced by a definite provision called a jointure, usually made in lieu thereof. This was rendered necessary by the fact that, under the system of uses, lands were commonly held by those who had only a beneficial interest therein and not the legal title, and there could be no dower in a purely beneficial or equitable estate. Upon the abolition of uses by the Statute of Uses in 1535 (27 Hen. VIII, c. 10) the right of dower revived, and it was expressly provided that the wife might elect between her jointure and her dower, but should not be entitled to both. See **JOINTURE**; **USE**.

Both in England and in many of the United States modern statutes have materially modified the dower rights of the wife. Where dower is preserved by such statutes, the husband is usually given power, by his own act or deed alone, to bar it as to property which he desires to sell during the coverture. In England by the Dower Act of 1833 (3 and 4 Wm. IV, c. 105) dower is barred by any expression of intention by the husband, whether direct or indirect, contained in any deed or will executed by him, that his wife shall not have dower in his lands or any part of them. In some of the United States in which a widow is given the right of inheritance, dower has been wholly abolished.

In most of the older States, however, the common-law dower is still retained. In the absence of statutory changes there are several ways in which dower may be barred. These are: 1. By an absolute divorce. In the absence of statu-

tory qualifications such a divorce bars dower only where it was obtained because of the misconduct of the wife. But in some of the States a dissolution of the marriage tie for any cause ipso facto puts an end to the wife's claim to dower. 2. If the wife join in the deed by which her husband conveys real estate, she thereby releases her dower and is barred from subsequently claiming it. It is in order to secure this result that the wife commonly joins in her husband's conveyance. 3. If the wife induce any one to purchase her husband's real property by representing to him that she has no dower right therein, she will be estopped or precluded from subsequently claiming dower in that property against such purchaser or those who claim under him. 4. If the title of the husband be defeated, either while he lives or after his death, by one who claims under a paramount title, this will also defeat the wife's dower. 5. When, by the exercise of the right of eminent domain, the State takes real estate from the husband and makes compensation to him for it, the wife's right of dower in the property so taken is barred. But she may follow the proceeds and claim her dower in that. So far as the right of dower is still recognized, it extends to equitable as well as to legal estates of inheritance. This has always been the rule in the United States and was made a part of the English law of dower by the Dower Act, above referred to. See HUSBAND AND WIFE: MARRIED WOMAN; and, for the corresponding right of the husband in the inheritable property of the wife, see CURTESY.

Blackstone, *Commentaries on the Laws of England*; Digby, *An Introduction to the History of the Law of Real Property* (5th ed., London, 1897); Jenks, *Modern Land Law* (Oxford, 1899); Kent, *Commentaries on American Law* (12th ed., Boston, 1873); Washburn, *A Treatise on the American Law of Real Property* (6th ed., ib., 1902); Scribner, *The Law of Dower*; Pollock and Maitland, *History of English Law* (2d ed., Cambridge and Boston, 1899); Giaque and McClure, *Tables for Ascertaining the Present Value of Vested Rights of Dower* (4th ed., Chicago, 1904); McKean, *Practical Life Tables, with Rules and Formulæ for the Solution of Cases of Dower* (2 vols., Albany, 1907).

DOWIE, dou'ī, JOHN ALEXANDER (1847-1907). The self-styled "First Apostle of the Lord Jesus the Christ, and General Overseer of the Christian Catholic Apostolic Church in Zion"; also, "Elijah II." He was born in Edinburgh, studied in the university there, returned to Sydney, Australia, where his family had gone in 1860, entered the ministry, and was ordained a clergyman of the Congregationalist denomination in South Australia. He was prominent in politics and social reform and in 1878 went into evangelistic work, feeling it was wrong to take a minister's salary. In 1882 he established an independent tabernacle in Melbourne and about this time took up residence in Chicago. He came to the United States in 1886, organized his "church," which in 1901 was established at Zion City—so named by him—on the shore of Lake Michigan, 42 miles north of Chicago. In 1903 Dowie led his "hosts" to New York City to regenerate the metropolis. In 1906 Zion City revolted against him and finally suspended him from the church, charging him with misuse of investments, tyranny, polygamous tendencies, and other offenses. Consult Harlan, *John Alexander Dowie and the Christian Catholic Apostolic Church* (Evansville, 1906), a University of Chicago doctoral dissertation, and E. Sheldrake (ed.), *The Personal Letters of John Alexander Dowie* (Zion City, 1912).

DOWITCHER, dou'ich-ēr (corruption of Ger. *deutsch*, German, or Dutch *duitsch*, Dutch). A popular name for certain shore birds. They constitute the genus *Macrorhamphus*, are closely related to the snipes (q.v.), and are often called gray snipe, or red-breasted or red-bellied snipe. The bill is distinctly snipelike, but the tail and feet are like those of sandpipers. Two species are recognized, but during the migrations one species (*Macrorhamphus griseus griseus*) is found along the Atlantic coast of the United States, while the other, the long-billed (*Macrorhamphus griseus scolopaceus*), migrates through the Mississippi Valley and Western States. The dowitchers are about 10 or 12 inches in length, with a bill 2 to 2½ inches long. The upper parts are chiefly black or blackish (in winter, brownish gray), and the under parts dull pale rufous, more or less marked with black. See Plate of BEACH BIRDS.

DOW'LAS (probably from *Doullens*, a town of France). A coarse, strong unbleached linen, much used in the sixteenth century and said to have been made at Doullens, France. It was largely manufactured in southern Scotland and in Yorkshire in the eighteenth century and used by working people for shirts and aprons. The term is also applied to a cotton cloth finished to imitate linen.

DOW'LER, BENNET (1797-1879). An American physician. He was born in Moundville, Va., graduated at the medical school of the University of Maryland, and in 1836 settled in New Orleans, where he founded the Academy of Sciences and for some years edited the *New Orleans Medical and Surgical Journal*. His experiments resulted in valuable discoveries in contractibility, calorification, and capillary circulation. He wrote a *Tableau of the Yellow Fever of 1853* (1854).

DOW'LING, JOHN (1807-78). An American Baptist clergyman. He was born at Pevensey, Sussex, England, and settled in the United States in 1832. He wrote *History of Romanism* (1845; revised 1871), and many other works.

DOWN. A maritime county in the southeast of Ulster Province, Ireland (Map: Ireland, F 2). Area, nearly 950 square miles. It has a low, rocky coast line of 67 miles, or 125 by the inlets, skirted by many islets. The Mourne Mountains cover 90 square miles in the south and rise 2796 feet in Slieve Donard. Several other peaks exceed 2000 feet. Mineral springs occur frequently. Miraculous healing powers were believed to be possessed by the springs near Downpatrick, where extravagant religious demonstrations occurred until 1849. The chief crops are oats, potatoes, and turnips. The cultivation of flax, once an important product, has been practically abandoned. Many hogs are raised. The chief manufacture is linen, especially the finer fabrics, such as muslin, woven in the houses of the small farmers. Hosiery, leather, salt, thread, and woollens are also made. These, with corn, butter, pork, and hides, are the chief exports. Capital, Downpatrick. Pop., 1841, 368,200; in 1891, 219,405; 1901, 205,889; 1911, 204,303.

DOW'NCAST. Where mines have two or more shafts or openings, the downcast shaft is the one through which the fresh air from the surface enters the workings. When ventilation

is not forced by using a fan or stove, the direction of the ventilating current changes with the seasons or temperature of the outside air. In the winter, or when the temperature of the outside air is much lower than the temperature of the mine air, the shaft having the lowest elevation will be the downcast and vice versa.

DOWNERS GROVE. A village in Dupage Co., Ill., 21 miles by rail west of Chicago, on the Chicago, St. Louis and Quincy Railroad (Map: Illinois, 1900, 2103; 1910, 2601). It contains a public library. The chief manufactures are electric linemen's tools and furniture, and there are large dairy and greenhouse interests. The water works and electric-light plant are owned by the village. Pop., 1900, 2103; 1910, 2601.

DOWNING, ANDREW JACKSON (1815-52). An American nurseryman, landscape gardener, and pomologist, born at Newburgh, N. Y. His influence upon American horticultural development is probably unsurpassed. To him must be accredited the introduction and development of the free school of landscape gardening in America. He planned the grounds about the National Capitol, the White House, and the Smithsonian Institution in Washington, D. C. To his foresight, and to his spirit as communicated to others, we owe our present American system of broad free municipal parks. Downing's monumental work, *Fruits and Fruit Trees of America* (1845), greatly extended by his brother Charles (q.v.), together with his numerous essays, forms the bulk of his contribution to the literature of horticulture. Another important work is the *Treatise on the Theory and Practice of Landscape Gardening* (1841). These essays were first published in the *Horticulturist*, of which he was editor at the time of his death, and afterward in book form under the title of *Rural Essays* (1854), for which book George William Curtis wrote a memoir of Downing. He was drowned while attempting to save the lives of others on the burning Hudson River steamer *Henry Clay*.

DOWNING, CHARLES (1802-85). An American nurseryman, the elder brother of A. J. Downing (q.v.). He was born at Newburgh, N. Y. He was one of those who put nursery gardening on a scientific basis. In fact, his nursery became so much of an experiment station that after the death of his brother, with whom he had collaborated, he abandoned commercial horticulture and devoted himself for the remainder of his life to the amplification and revision of *The Fruits and Fruit Trees of America*. His efforts more than doubled the original scope of the volume and made him until his death a recognized authority throughout the world on all questions pertaining to pomology, horticulture, and tree growth.

DOWNING, SIR GEORGE (c.1623-84). An English soldier and politician. He was born in Dublin and was the nephew of Gov. John Winthrop, who induced him to study at Harvard College, from which he graduated as a member of its first class (1642). Some years afterward he went to England and served in the parliamentary army. During the Protectorate he was a member of both parliaments, was a leader of the movement for offering the crown to Cromwell, and in 1655 was sent to France to protest against the Vaudois massacre. In 1657 he became British resident at The Hague. He ingratiated himself with the exiled Stuarts, however, and after the Restoration was instrumental

in arresting three regicides. He was knighted in 1660 and made a baronet in 1663 and became Secretary of the Treasury and one of the Commissioners of Customs. Downing Street, Whitehall, derives its name from him. Pepys called him a "perfidious rogue," and in New England his name became a synonym for a traitor.

DOWNING COLLEGE. A college of Cambridge University, founded by Sir George Downing, of Gamlingay Park, Cambridge, who died in 1749, leaving his estates to be appropriated to the founding of a college in Cambridge after various trust provisions had expired. The succession on which the trust depended dying out, a charter was obtained in 1800 for a college devoted especially to the study of law and medicine, for a master, two professors, and 16 fellows. The original scheme was straitened by costly litigation, and only two sides of the quadrangle have so far been completed. The statutes were framed in 1805 and altered in 1860. The college had, in 1913, a master, 12 fellowships, restricted to law and medicine, and 23 scholars. In 1913-14 there were 116 undergraduates. Consult H. W. Stevens, *Downing College* (London, 1899).

DOWNING STREET. A street in the South West district of London, leading from Whitehall. The Foreign Office and Colonial Office are located in it, and the name is used as a convenient synonym for the central powers of the British government.

DOWNINGTOWN. A borough in Chester Co., Pa., 33 miles west of Philadelphia, on the Pennsylvania and the Philadelphia and Reading railroads (Map: Pennsylvania, K 8). It has paper mills, brickyards, a knitting mill, and machine shops. Pop., 1900, 2133; 1910, 3326.

DOWNPATRICK, or DOWN. A municipal borough and cathedral town in the County of Down, Ireland, of which it is the capital (Map: Ireland, F 2). It is situated near the mouth of the Quoyle, at the end of Lough Strangford, 21 miles south-southeast of Belfast, with which town it is connected by railway. The cathedral in its present form was restored in 1790 on the site of one built in 1412 and burned in 1538. Vessels of 100 tons reach the quay a mile from Downpatrick. It has manufactures of linen, muslins, soap, leather, and malt liquors. Pop., 1901, 2993. Downpatrick is believed to be the oldest town in Ulster Province. It was the residence of the kings of Ulster and was famous before the arrival of St. Patrick, who built near here the Abbey of Saul and the Abbey of Canons and by some is believed to have been buried here. Consult *Ecclesiastical Associations of Downpatrick* (Belfast, 1897).

DOWNS (AS, OHG. *dūn*, Ger. *düne*, Fr. *dune*, from Ir. *dūn*, Welsh *din*, hill, fort; ultimately connected with AS, Icel. *dun*, Eng. *town*, OHG. *zūn*, Ger. *Zaun*, hedge). A term usually applied to hillocks of sand thrown up by the sea or the wind along the seacoast. It is also a general name for any undulating tract of upland too light for cultivation and covered with short grass. It is especially applied to two broad ridges of undulating hills in England south of the Thames, beginning in the middle of Hampshire and running eastward, the one (the North Downs) through the middle of Surrey and Kent to Dover (about 120 miles), and the other (the South Downs) through the southeast of Hampshire and near the Sussex coast to Beachy Head (about 80 miles). The highest point of the North Downs is Botley Hill, 880 feet, and that

of the South Downs, Ditchelling Beacon, 858 feet. These uplands are covered with fine pasture, forming excellent feeding ground for the famous Southdown sheep. The valleys among the hills are usually fertile and admit of cultivation, so that an excellent field is furnished for mixed husbandry.

DOWNS, THE. An important English roadstead off the east coast of Kent, between Ramsgate and Deal, with a maximum depth of 12 fathoms, affording harborage except during heavy south winds (Map: England, G 5). It is protected externally by the Goodwin Sands, a natural breakwater with 1 to 4 fathoms of water, and often partly dry at low tide. It is defended by Deal, Dover, and Sandown castles. The Downs were the scene of a victory of the Dutch over the Spaniards in 1639 and of a naval battle between the Dutch and English in 1666.

DOWNY MILDEW. See MILDEW; PHYCOMYCETES.

DOWRY (from *dower*, AS. *dowere*, OE. *doaire*, Fr. *douaire*, Prov. *dotaire*, from ML. *dotarium*, from Lat. *dos*, dowry; connected with Lat. *dare*, Gk. *διδόναι*, *didonai*, Skt. *dā*, to give). The property which the wife brings to the husband, as her marriage portion. Though recognized at the common law and often forming in England an important element in the arrangement known as a marriage settlement, it is scarcely known in the United States, except in Louisiana. There, as in most countries which have adopted the system of the civil law, it constitutes a distinct as well as an important form of property. It is given to the husband, who has exclusive control and administration of it during marriage, to be employed in defraying the expenses of the family. The wife cannot deprive the husband of its control. On the other hand, he is not allowed to alienate real estate which comes to him as dowry. In the United States and England property so contributed by the wife to the common fund, though legally vested in the husband, may be protected by him from the claims of his creditors. Dowry is to be distinguished from dower, or the common-law right of the wife in the real estate of her husband, with which it is sometimes confounded. See DOWER.

DOWSING. See DIVINING ROD.

DOXOLOGŶ (ML. *doxologia*, Gk. *δοξολογία*, from *δόξα*, *doxa*, glory, from *δοkein*, *dokein*, to seem + *-λογία*, *-logia*, speech, from *λέγειν*, *legein*, to say). An ascription of glory or praise to God. Brief expressions of the kind are frequent in the Bible, as Rom. xvi. 27; Eph. iii. 21; Jude 25; Rev. v. 13, xix. 1. Certain special doxologies are used in various liturgies. The Lesser Doxology, or *Gloria Patri* ("Glory be to the Father, and to the Son, and to the Holy Ghost; as it was in the beginning, is now, and ever shall be, world without end, amen"), seems first to have come into use in the fourth century, as a profession of faith, in opposition to a variant formula, which had been appropriated by the Arians. It is used by the Roman Catholic church at the end of every psalm and canticle, except the *Te Deum* and *Benedicite*, and in all the responsories of the breviary. It is omitted, however, as a song of praise unsuitable to times of mourning, on the last three days of Holy Week and in the office of the dead. The Anglican church uses it at the end of psalms and canticles. The use of the Greater Doxology, or *Gloria in Excelsis* (sometimes called the angelic

hymn, from its being an expansion of the song of the angels in Luke ii. 14), can be traced back to the fourth century, and it appears in the Roman liturgy at the beginning of the sixth century. It is used in the Roman mass, except in Advent and Lent, and at all times in the Anglican communion service. The *Trisagion* ('thrice holy') is the seraphic hymn (Isa. vi. 3). The last stanza of a hymn written by Bishop Thomas Ken (1637-1711), beginning, "Praise God from whom all blessings flow," is commonly called "the Doxology" in Protestant churches.

DOYEN, dwā'yān', EUGÈNE LOUIS (1859-). A French surgeon, born in Rheims (Marne), and noted for his discoveries in surgery and his investigations in cancer. After introducing numerous innovations in general and surgical technique, he established in Paris in 1895 a private clinic, which soon became a centre of study for both French and foreign surgeons. His improvements in surgical methods were quickly adopted, and he became a leader in the new French school of surgery. He claimed to have discovered the germ of cancer, but this claim has not been substantiated by other investigators. In 1898 he received the degree of LL.D. from Edinburgh University, where he applied the method of teaching surgery by means of the cinematograph. Among his publications are: *Traitément de cancer* (1904); *La maladie et le médecin* (1906); *Traité de thérapeutique chirurgicale et de technique opératoire* (1907); *Le cancer* (1909).

DOYEN, GABRIEL FRANÇOIS (1726-1806). A French historical painter. He was born in Paris and studied under Van Loo. After obtaining the Prix de Rome (1748) he remained for several years in Italy, studying the works of Carracci, Cortona, and other celebrated masters. In 1767 he produced his celebrated painting, the "Miracle des Ardens" (Saint-Roch, Paris), which was followed by the "Death of St. Louis" (Saint-Eustache, Paris); "Triumph of Amphitrite" (Louvre); "Adoration of the Magi" (Darmstadt Museum); and paintings in St. Gregory's Chapel in the Invalides (Paris). All of these compositions are in the style of the late eighteenth century and, though effective, are cold in color. In 1791 he was called to St. Petersburg, where he was charged by Catharine II and Paul I with decorations for the Winter Palace and the Old Hermitage.

DOYLE, ALEXANDER (1857-). An American sculptor. He was born at Steubenville, Ohio, and studied at the academies of Florence, Carrara, Rome, and Paris. He is at his best in large monumental and military figures, such as the bronze equestrian statues of the Confederate Generals Johnson and Lee at New Orleans; the monument to Francis Scott Key at Frederick, Md.; the bronze statue of Horace Greeley in New York City; the statues of Senators Thomas Benton, Franklin P. Blair, and John E. Kenna in the United States capitol; General Garfield in Cleveland, Gen. Philip Schuyler on the National Revolutionary Monument, Saratoga; the statue of "Peace" on the Revolutionary Monument at Yorktown; and the Soldiers' Monument at New Haven. Among more recent works are the statue of E. M. Stanton, Steubenville, and the equestrian statue of General Beauregard, New Orleans.

DOYLE, SIR ARTHUR CONAN (1859-).

A British novelist, born in Edinburgh, the grandson of John Doyle the caricaturist, and nephew of Richard Doyle of *Punch*. He studied medicine at the University of Edinburgh, and was a practicing physician from 1882 until 1890. He traveled extensively in the Arctic regions and on the west coast of Africa. He early tried his hand at fiction, and, after writing a number of unsuccessful books, he produced in 1887 *A Study in Scarlet*, in which he created the famous detective, Sherlock Holmes. Other books of his in which Holmes appears are: *The Sign of the Four* (1889); *The Adventures of Sherlock Holmes* (1891); *The Memoirs of Sherlock Holmes* (1893); *The Hound of the Baskervilles* (1902); *The Return of Sherlock Holmes* (1904). In these stories the author displays rare fertility and ingenuity of invention, humor, and a power of imbuing his narrative with an atmosphere of fascinating mystery and, at times, of horror; so that the best of the stories approach the similar productions of Edgar Allan Poe. Doyle also won much success by several historical novels: *Micah Clarke* (1888); *The White Company* (1890); *The Refugees* (1891); *The Great Shadow* (1892); *Rodney Stone* (1896); *The Exploits of Brigadier Gerard* (1896). *The Adventures of Gerard* (1903) is an exceedingly clever book, of which the hero is a typical *vueux moustache* of Napoleon's Grand Army. *Sir Nigel* (1906) is considered by many critics his best production in historical fiction. Volumes of short stories are: *Round the Red Lamp* (1894); *The Stark Munro Letters* (1895); *The Green Flag and Other Stories* (1900). In 1898 appeared a volume of poems entitled *Songs of Action* and in 1899 a play called *Halves*. Other works are *The Tragedy of the Korosko*, a story of the Egyptian Soudan (1898), and *A Duet with an Occasional Chorus* (1899). During the Boer War Doyle visited South Africa and acted as senior physician of the Langman Field Hospital. Returning to England, he published a military history, entitled *The Great Boer War*, which appeared in 1900 and of which an enlarged edition was issued in 1902. He also wrote *The Cause and Conduct of the War* (1903), a spirited defense of the British policy in South Africa, and this was widely circulated and translated into 12 languages. As a recognition of his services to the government, the author was knighted in 1902. Later publications of his are: *The Crime of the Congo* (1910); *The Lost World* (1912); *The Poison Belt* (1913).

DOYLE, SIR FRANCIS HASTINGS CHARLES (1810-88). An English poet. He was born at Nunappleton, near Tadcaster, and was educated at Oxford. From 1867 to 1877 he was professor of poetry at Oxford. He published several books of verses, his poetic work being chiefly remarkable for his treatment of the ballad. His publications include: *Miscellaneous Verses* (1834; reprinted with additions in 1840); *Two Destinies* (1844); *Return of the Guards and Other Poems* (1866); and his *Reminiscences* (1866).

DOYLE, JOHN (1797-1868). An Irish painter and caricaturist, born in Dublin. He studied first under Gabrielli, then at the Royal Dublin Society's schools, and afterward under the miniature painter Cumerford. In 1821 he came to London, and some of his portraits were exhibited at the Royal Academy, but without much success. He then turned his at-

tention to caricature and also worked in lithography. For many years (1828-50) he published a series of monthly political sketches, signed "H. B.," which were usually commented upon in the London *Times*. His identity remained unknown until 1850. His satire was very different from that of his coarse and violent, if vigorous, predecessors. He was always refined, never tending towards burlesque, and established what may be called a gentlemanly style of caricature. Thackeray, Macaulay, Haydon, and Wordsworth have praised his work, and his sketches throw much light on the political history of England between the years 1830 and 1845, for every man of note in political England became known through his pencil. There are more than 600 examples of his work in the British Museum, including 314 of the original designs of his 917 *Political Sketches*. One of his most important designs is the drawing for "The Reform Bill Receiving the King's Assent by Royal Commission" (1836), engraved by Walker and Reynolds. He also published *The Life of the Race Horse* (1822, 6 plates).

DOYLE, JOHN ANDREW (1844-1907). An English writer of American history, the son of Andrew Doyle, editor of the *Morning Chronicle*. He was educated at Eton and at Balliol College, Oxford, where he took his M.A. degree in 1869, winning the Arnold Prize Essay on the subject of *The American Colonies*, which, when published the following year, attracted wide attention as a defense of the American Revolution by an Englishman. He became a fellow of All Souls in 1869. His later works were *A History of the United States* (1875) and *The Republic in America*—"Virginia, Maryland, and the Carolinas" (1882), "The Puritan Colonies" (2 vols., 1887), "The Middle Colonies" (1907), and "The Colonies under the House of Hanover" (1907); and he contributed valuable chapters to the seventh volume of the *Cambridge Modern History*. His *Essays on Various Subjects* was published posthumously (London, 1911), ed. by Ker, with introduction by Sir W. Anson; it includes several articles on sport-rifle shooting, the turf, racehorse breeding, and harriers—as well as valuable historical and critical essays.

DOYLE, RICHARD (1824-83). An English water-color painter and caricaturist, born in London in September, 1824. He was the son and pupil of John Doyle, from whom he inherited his talent. Its early development is proved by a sketchbook of 1840 in the British Museum, a facsimile of which was published in 1885. Doyle was one of the early contributors to *Punch*, but resigned his position on the staff in 1850 because of that journal's hostile attitude towards the Catholics. "What has become, with slight permanent cover of the journal. He furnished illustrations for Thackeray's *Newcomes*, Ruskin's *King of the Golden River*, Leigh Hunt's *Pot of Honey*. The best known of his humorous stories, told in pictures, are the "Adventures of Brown, Jones, and Robinson" and "Mr. Pip's Diary," originally contributed to *Punch*. The British Museum, the Fitzwilliam Museum, Cambridge, National Gallery, Dublin, and National Portrait Gallery, Edinburgh, are rich in his caricatures, which are distinguished by genial humor and graceful drawing. He also exhibited many water colors in the Grosvenor Gallery, among the best of which were "Under the Dock Leaves" and two Scottish landscapes (British

Museum); "Wood Elves Watching a Lady" (South Kensington Museum); "Thor" (Fitzwilliam Museum, Cambridge); "The Triumphant Entry," a fairy pageant (National Gallery, Dublin).

DOYLESTOWN. A borough and the county seat of Bucks Co., Pa., 34 miles north of Philadelphia, on the Philadelphia and Reading Railroad (Map: Pennsylvania, L 7). It has a public library, fine courthouse, and county historical society. The industries comprise a shoe factory, hosiery, silk, and worsted mills, creameries, saw and flour mills, agricultural-implement works, brick and tile works, a spoke factory, and foundry. The water works are owned by the borough. Pop., 1900, 3034; 1910, 3304.

D'OYLY, GEORGE (1778-1846). A Church of England divine. He graduated B.A. at Cambridge, became rector in London (1820), and was one of the principal promoters of the establishment of King's College, London. He is chiefly remembered as joint author with Richard Mant of D'Oyly and Mant's Bible, an annotated edition of the Bible published by the Society for Promoting Christian Knowledge (1814 and often since). Consult his *Memoir* by his son (London, 1847).

DÓZSA, dō'zhō, GEORGE (?-1514). The leader of the Peasant War in Hungary (1514), sometimes called Székely. At the head of a large army (estimated by some at 60,000 men) originally designed for a crusade against the Turks, Dózsa led a rebellion in the course of which many excesses were committed. While his army lay before Temesvár, which came near falling into his hands, Dózsa was taken prisoner. His forces were dispersed, he was roasted alive on a heated throne, and his body was fed to some of his followers who had been kept without food during the preceding week. The rebellion is the theme of the novel by Eötvös entitled *Magyarország 1514-ben* (1847; Ger. trans. by Dux under the title *Der Bauernkrieg in Ungarn*, 1850). There is a play in *Magyarország* (Budapest, 1884) by Marki.

DOZY, dō'zē, REINHART (1820-83). A noted Orientalist, descended from a French family settled in Holland, and born at Leyden. He pursued a course of study at the University of Leyden and obtained the doctor's degree in 1844. Until 1850 he was at the University of Leyden, where he was made assistant professor, and in 1857 full professor, of history. His first important work was published in Amsterdam (1845), under the title *Dictionnaire détaillé des noms des vêtements chez les Arabes*. In 1846 appeared the *Scriptorum Arabum loci de Abbadidis* and the *Commentaire historique sur le poème d'Ibn Abdoun par Ibn Badroun*. Among his other works are: *History of the Almohades* (1847; 2d ed., 1881); *Histoire de l'Espagne* (1848; supplement, 1849); *sur l'histoire et la littérature de l'Espagne pendant le moyen âge* (1849; 3d ed., 1881); *Al Makkari, Analectes sur l'histoire et la littérature des Arabes d'Espagne* (1855-61); *Histoire des Musulmans d'Espagne jusqu'à la conquête de l'Andalousie par les Almoravides* (1861); *Het Islamisme* (1863); *De Israëlieten te Mekka* (1864). His most important contribution to Arabic philology was his *Supplément aux Dictionnaires Arabes* (2 vols., 1877-80), which is invaluable to all students of Arabic and is based on an exceed-

ingly extensive study of Arabic authors of all classes. Consult De Goeje, *Biographie de Reinhart Dozy traduit par Chauvin* (1883).

DRA, drā. A partially dried-up river or wadi, of southern Morocco, Africa, the longest watercourse of the country (Map: Africa D 2). It rises in numerous head streams on the south slopes of the Central Atlas Range, and after crossing the oasis of Ed Dra flows southwest, emptying into the Atlantic just south of Cape Nun. It is only, however, by the aid of the melted snow of the Atlas summits that its waters are sufficiently increased to be enabled to reach the ocean; in the dry season its course ends a long distance from the coast.

DRACENA DRACO (Lat., from Gk. δράκαινα, *drakaina*, she dragon, from δράκων, *drakōn*, dragon), or **DRAGON TREE.** A tree of the family Liliaceae, that produces the resin called dragon's blood. Its thickness is greatly out of proportion to its height. The head is crowned with short branches bearing tufts of sword-shaped leaves. Humboldt saw a famous specimen in Teneriffe, which at the time of his visit was 70 feet tall and 45 feet in circumference and was estimated to be 6000 years old. It was destroyed by a storm in 1868. Others of large size are reported from the Canary Islands and India. Another source of dragon's blood is the resinous exudate from the fruit of *Calamus draco*. Similar substances are obtained from *Lingoum draco* and *Oroton gossypifolius*.

DRACHENFELS, drā'en-fēls (Ger., Dragon's Rock). A mountain of Prussia, in the Siebengebirge Range (q.v.), situated on the right bank of the Rhine, about 8 miles southeast of Bonn, with an elevation of 1066 feet (Map: Prussia, B 3). It rises abruptly from the river and is covered with brushwood almost to the top, whence the prospect is magnificent, extending down the river as far as Cologne, and having a charming foreground in Bonn, with its University and numerous old and time-worn castles. About half way up the mountain is the cave which, according to the legend, was occupied by the dragon slain by Siegfried. Of the mediæval castle of Drachenfels, erected on the summit of the mountain, only a solitary tower remains. The mountain, which has been extensively quarried, is the property of the state and can be ascended by rail.

DRACHMA, drāk'ma, DRACHM, drām, or DRAM (Lat., from Gk. δραχμή, *drachmē*, handful, from δράσσειν, *drassein*, to grasp). The name of a Greek measure of weight and of a Greek coin. The measure of weight was equal to six small bars of silver (δραχμοί) or a handful (this ancient explanation has, however, been questioned in modern times); 100 drachmas formed a mina and 6000 a talent. The weight varied somewhat in different places and at different times, but, as used in trade, seems to have been from 6 to 6.5 grams. The silver coin called drachma was the ordinary unit of the ancient Greek monetary system. Here also there were local differences; but two main systems are clearly marked—the Æginetan, with a drachma of about 6.3 grams, or frequently somewhat less; and the Eubœic-Attic, with a drachma of about 4.3 grams of pure silver, or about 18 cents in the United States standard coinage. Thus, the Attic mina was worth about \$18 and the Attic talent about \$1080. The drachma is also the name of the monetary unit in modern Greece. Since 1867, when Greece joined the Latin Union,

it has been of the same weight and fineness as the French franc. In the British system of weights there were, till recently, two drachms or drams—the avoirdupois dram, equal to 27 $\frac{1}{2}$ troy grains, and the apothecaries' dram (not now used), equal to 60 troy grains, or $\frac{1}{8}$ of an ounce troy. See Plate I of NUMISMATICS.

DRACHMAN, drāk'mān, BERNARD (1861–). An American rabbi and author, born in New York City. He graduated at Columbia in 1882, studied at Heidelberg and Breslau, and became a rabbi in Breslau in 1885. In 1887 he was appointed professor of biblical exegesis and Hebrew philosophy in the Jewish Theological Seminary of New York, and in 1889 dean of the seminary and rabbi of the Congregation Zichron Ephraim, and from 1902 to 1908 was professor of Bible and Rabbinical codes. In 1909 he became rabbi of the Congregation Ohab Zedek. He consistently supported the traditional Judaistic faith. His publications include: *Die Stellung und Bedeutung des Judentums in der Geschichte der hebräischen Nation* (1885); *From the Heart of Israel: Jewish Tales and Types* (1905); a translation into English (1899) of S. R. Hirsch's German work, *The Nineteen Letters of Ben Uziel*.

DRACHMANN, drāc'mān, HOLGER (1846–1908). Danish poet, playwright, and novelist, born in Copenhagen. He studied art, but in 1877 wrote *From over the Border*. The modern movement in Danish literature dates from his *Poems* (1877), and his novels of seafaring life, *On a Seaman's Word and Honor* (1878) and *Paul and Virginia under Northern Latitudes* (1879). His poems include: *Subdued Melodies* (1878); *Old Gods and New* (1881); *Mountain Songs and Romances* (1885); *Motley Leaves* (1901). He wrote many fairy plays, including *Once upon a Time* (1885), which was very successful, and melodramas, *Brav-Karl* (1897); *Green Hope* (1901). Among his novels are: *With a Broad Pencil* (1887); *Prescribed* (1890); *Dædalus* (1900).

DRA'CO (Lat., from Gk. Δράκων, *Drakōn*). An Athenian legislator. It was he who, as Thesmothete, in 621 B.C. put into written and codified form the common law of Athens. To a later age this legislation bore the stamp of severity and cruelty, it being said of the laws that they were written, not in ink, but in blood. In every case, no matter what the offense, the penalty was death. We are not, however, to assume that Draco was more severe than his age; it is more probable that he simply put in writing the ordinances that the archons had been accustomed to enforce without writing, and the old Attic common law, when thus reduced to writing, appeared harsh and rigorous to a milder age. Connected with the legislation was the court of appeal, the Ephetæ, judges of life and death, whose number was 51. These laws, except those on homicide, were repealed by Solon. Draco is said by Suidas to have met his death at Ægina, being stifled in the theatre by the garments thrown upon him by the people as a mark of respect, and approval of his act in reducing the laws to writing. Consult Holm, *Griechische Geschichte*, vol. i (Berlin, 1886).

DRA'CO. A northern constellation situated just below the celestial pole. It contains the pole of the ecliptic. The star γ Draconis is celebrated as the one used by Bradley (q.v.) in discovering the aberration of light (q.v.). It is a bright star, nearly in the solstitial colure,

and consequently the minor axis of the small aberrational ellipse, which its apparent place describes in the heavens, lies in the meridian at its transit. Moreover, at the two equinoxes, when its apparent place is at the extremities respectively of this minor axis, it can be observed on the meridian at one equinox about sunrise and at the other about sunset, so that both observations may be made without the interference of a too bright daylight. These two observations therefore are easily taken, and the difference in the north polar distance which they give is the minor axis of the ellipse described by the apparent place of the star.

DRA'CONTIC MONTH. See MONTH.

DRACONTIUM, drā-kōn'shī-ūm. See SKUNK CABBAGE.

DRACONTIUS, drā-kōn'shī-ūs, BLOSSIUS ÆMILIUS. A Latin poet who lived and practiced as an advocate at Carthage during the latter half of the fifth century. Though his style is often spoiled by rhetorical exaggeration, his verses are framed on classical models and are of considerable merit; they prove also his familiarity with the Bible and with classical Latin writers. His extant works are two epithalamia; a collection of short epics on subjects taken from mythology; a Christian didactic poem in three books, entitled *De Laudibus Dei* (part of book i, containing an account of the story of the creation, was at an early date edited separately under the title *Hewæmeron*); an elegiac poem, *Satisfactio*, in which he apologizes to the Vandal King, Gunthamund (484–496 A.D.), for having praised one of his enemies; and several distichs, *De Origine Rosarum* and *De Mensibus*. Owing to resemblance in style and metre to the practice of Dracontius, the *Orestis Tragedia*, formerly attributed to Horace or Lucan, is now generally ascribed to Dracontius. Dracontius was edited by Arevalo (Rome, 1791). The *Carmina Minora* of Dracontius were edited by De Duhn, some of them for the first time (Leipzig, 1873). The *Orestis Tragedia* has been edited by Peiper (1875) and Giarratino (Milan, 1906). Consult also Rossberg, *De Dracontio* (Göttingen, 1880).

DRACUT. A town in Middlesex Co., Mass., 4 miles west of Lowell (Map: Massachusetts, E 2). It is in an agricultural region and has woolen mills. The water works are owned by the town. Pop., 1900, 3253; 1910, 3461.

DRAESEKE, drā'se-ke, FELIX AUGUST BERNHARD (1835–1913). A German composer, born in Coburg. He studied at the Leipzig Conservatory under Rietz and became a friend and pupil of Liszt at Weimar. He taught in the Lausanne Conservatory, the Royal Music School at Munich, and in 1884 became a teacher in the Dresden Conservatory. Although at first an extreme follower of Wagner and Liszt, his later works are more moderate and have met with the success due them. His compositions include five operas—*Sigurd* (1867); *Gudrun* (1884); *Bertrand de Born*; *Merlin* (1906); *Herrat* (1892); three symphonies and much excellent chamber music. His importance rests upon his great vocal works with orchestra, a mass in F \sharp m., a *Requiem* in B m., the Easter scene from Goethe's *Faust*, and his great Mystery *Christus* (a cyclus of three oratorios preceded by an elaborate Prelude). Consult H. Platzbecker, *Felix Draeske*, in vol. iii *Monographien Moderner Musiker* (Leipzig, 1909).

DRAFT (variant of *draught*, from AS.

dragan, Icel.. *draga*, Goth. *dragan*, to draw, OHG. *tragan*, Ger. *tragen*, to carry). A popular synonym of bill of exchange, or of a check drawn by one bank on another. It is also less commonly applied to a non-negotiable order for the payment of money. Sometimes this form of draft is intended to operate as a written authority to the payee to collect the amount of the order from the drawee for the benefit of the drawer; at other times, as a voucher or warrant for payment by a disbursing officer. See BILL OF EXCHANGE; CHECK; NEGOTIABLE INSTRUMENTS.

DRAFT RIOTS IN NEW YORK. A bloody disturbance which took place on July 13-16, 1863. The pressing need for more soldiers had compelled Congress to pass a conscription act (March 3, 1863), authorizing the President to recruit the army whenever necessary by a draft from "all able-bodied male citizens" between the ages of 20 and 45 years. Any man, however, might, after being drafted, procure exemption from service by the payment of \$300. The act was vigorously assailed as unconstitutional by the opponents of the administration, who also asserted that the exemption clause was a flimsy device for enabling the rich to evade service. Among those who adopted and proclaimed such views was Governor Seymour, of New York State, who seems also to have represented the attitude of many prominent men in New York City. On Saturday, July 11, the draft began, without opposition, in New York at one of the enrollment offices in the strongly Democratic Ninth District. On Sunday some drafted workingmen, aided by a number of political agitators, fomented the discontent of the populace and organized an opposition to enrollment. The draft was renewed at 10 A.M. on Monday, but the assistant provost marshal's office was soon attacked, demolished, and burned by a furious mob, which, after overcoming a squad of police sent against it, roamed about the city and, frenzied by excitement and drink, committed numberless outrages. The rioters, prejudiced against the negro and feeling that the draft had been occasioned by an "abolition war" everywhere pursued the blacks with unrelenting rancor and brutally assaulted, tortured, and killed many that fell into their hands. The Colored Orphan Asylum was attacked, sacked, and burned, and the offices of the New York *Tribune*, one of the papers which had upheld the administration, narrowly escaped destruction. On Tuesday the mobs, increased in number, continued to pillage, sack, burn, and kill, though in many districts they were sharply repulsed and partially dispersed by the police and militia. On Wednesday, the 15th, the assistant provost marshal general announced that the draft would be temporarily suspended, and militia regiments arriving from Pennsylvania rendered efficient service against the mobs. Large militia reinforcements arrived on the following day, and, though isolated bodies of rioters still defied the law, order was soon restored throughout the city. Before Friday morning the uprising had been suppressed. It is estimated that during these four days more than 1000 men had been killed, and property valued at over \$1,500,000 had been destroyed.

On August 19 the draft was resumed, and it was completed, without further resistance, within 10 days. Consult: the *Official Records*, vol. xxvii, part ii (Washington, 1889); Fry, *New*

York and the Conscription of 1863 (New York, 1885); Barnes, *The Draft Riots in New York* (ib., 1863); Nicolay and Hay, *Lincoln*, vol. vii (ib., 1890); Greeley, *The American Conflict*, vol. ii (Hartford, 1866).

DRAGA. Queen of Serbia and wife of Alexander I, with whom she was assassinated in 1903. See SERBIA.

DRAGE, drāj, GEOFFREY (1860-). An English sociologist, educated at Eton, Christ Church (Oxford), Berlin, and Moscow. He studied law at Lincoln's Inn and Middle Temple, but did not practice. In 1891-94 he was secretary of the Royal Commission on Labor, and he was a prominent delegate to the Milan Congress on Accidents (1894), the Brussels Congress on Housing of Working Classes (1897), and the Paris Congress on Poor Laws and Charity (1900). In 1895-1900 he was a Conservative member of Parliament for Derby. He published: *The Criminal Code of the German Empire* (1885); *Eton and the Empire* (1890); *Eton and the Labor Question* (1894); *The Unemployed* (1894); *The Problem of the Aged Poor* (1895); *The Labor Problem* (1896); *Russian Affairs* (1904); *Trade Unions* (1905); *Austria-Hungary* (1909); *The Imperial Organization of Trade* (1911), the first of a series on Imperial organization; *The State and the Poor* (1914). He wrote on recent Russian history in the *Cambridge Modern History*.

DRAG HUNT. See HUNTING.

DRAGO, LUIS MARÍA (1859-). An Argentinian jurist and diplomat. First devoting himself to criminal law and criminology he wrote *Antropología criminal* (2d ed., 1888) and another book, best known by its version into Italian (1890), called *I criminali-nati*. In 1902 and 1903, as Minister of Foreign Affairs for the Argentine Republic, he formulated the so-called "Drago doctrine." (See CALVO.) His definite statement of this doctrine appeared in his *Cobro coercitivo de deudas públicas* (1906); and he wrote *La república Argentina y el caso de Venezuela* (1903). As a member of The Hague Court, he dissented from the court's decision on question 5 in the Fisheries Arbitration of 1908-09.

DRAGO DOCTRINE. See CALVO.

DRAGOMAN (Fr. *dragoman*, *drogman*, OF. *droquemān*, *drogeman*, *drugement*, from Ar. *tarjumān*, interpreter). A name given in the East to interpreters, and hence to the professional guides who accompany travelers and make all arrangements, a service performed in Western Europe by a courier (q.v.). The dragomans attached to the embassies in Constantinople are more or less important official personages.

DRAGOMANOV, drā'gō-mā'nōv, MIKHAIL PETROVITCH (1841-95). A Russian scholar and author. He was born at Hadyatch, in the Government of Poltava. In 1865 he was appointed lecturer at the University of Kiev, where he had himself been educated and where he held the chair of general history until 1876. He criticized the educational system of Count Dmitri Tolstoy, which was based on German models of classicism, and refused to send in his resignation because of his Ukrainophil activity; but a special commission, appointed by Alexander II, found him guilty, and he was forbidden to reside in Little Russia and the capitals or to engage in literary pursuits. The Southern Section of the Geographical Society in Kiev was abolished, and the printing of books in the Little Russian

dialect was prohibited. Dragomirov went to Geneva, where he remained until made professor of history at the University of Sofia, in Bulgaria, in 1888. For over 20 years he fearlessly combated autocracy and oppression in all its forms. A strong nationalist, he advocated a complete reorganization of Russia on federative lines, with every nationality possessing equal and equitable representation. As he started out on the field of literary and political activity at a time when the terroristic doctrines were at their height, he stood for political execution, justified it on the ground of necessity and for the ultimate triumph of political liberty. His numerous works in the literary and historical field deal mostly with his native Little Russia, of which he was passionately fond. Beginning with *The Historical Songs of Little Russia*, published by him in collaboration with Professor Antonovitch, in 1874, Dragomirov incessantly worked on the history, folklore, and religious history of his country. After *The Question of Little Russian Literature* (1876), he published a series of popular pamphlets in the Little Russian dialect and, during 1878-82, five volumes of the periodical *Hromada* (*The Commune*). His *Le tyrannicide en Russie* appeared in Geneva (1876); *La Pologne historique et la démocratie moscovite* (1881); *The Political Songs in the Ukrainian Language in the Eighteenth and Nineteenth Centuries* (London, 1883-85).

DRAGOMIROV, dră'gô-mě'rôv, MIKHAIL IVANOVITCH (1830-1905). A Russian general. He studied at the War Academy in St. Petersburg, where, following further study abroad, he became professor of tactics in 1858. His lectures brought him considerable renown. In 1868, after participating in the Austro-Prussian War as military attaché, he was appointed major general and chief of the general staff at Kiev. As commander of the Russian advance guard in the Russo-Turkish War of 1877-78, he distinguished himself at the crossing of the Danube at Sistova. In consequence of wounds received in the fighting at the Shipka Pass he was compelled to retire from active service and was subsequently appointed director of the War Academy, where he exercised a most salutary influence upon military training. He was Governor-General of Kiev from 1898 to 1903, when he entered the Council of the Empire. His works include: *Lectures on Tactics* (1864); *The Austro-Prussian War* (1866); *Discipline and Subordination* (1894); *A Study of the Novel "War and Peace"* (1895); *The French Soldier* (1897); *War is an Inevitable Evil* (1897); *Joan of Arc* (1898); *Duels* (1900).

DRAGON (OF. *dragon*, Lat. *draco*, Gk. δράκων, *drakōn*, dragon, from δέσκειν, *derkesthai*, Skt. *dars*, to see). In the mythical history and legendary poetry of almost every nation the dragon appears as the emblem of the destructive and anarchic principle, as it manifests itself in the earlier stages of society, viz., as misdirected physical power and untamable animal passion striving against human progress. The earliest conception is embodied in the Babylonian myth of Tiamat—the great she dragon—who healed the Titanic hordes of Chaos, and whose destruction by the demiurge Merodach was the necessary prerequisite to an undisturbed and orderly universe. The destruction of the lower representatives of this disorderly element was one of the first objects of human energy, but,

being unattainable by merely human means, the task was assumed by that intermediate class of beings known as heroes in classical antiquity. As the highest ideal of human strength and courage, the task properly fell to Hercules (e.g., Dragon of the Garden of the Hesperides), but it was not confined to him, for we find both Apollo and Perseus represented as dragon slayers. From legendary poetry the dragon passed into art, some of the earliest efforts of which probably consisted in depicting it on the shield or carving it for the crest of a conqueror's helmet. It was used in this way as a sort of Medusa, an *apotropaion* or terror-striking image. Thus it was represented on the war standards of Germanic and Dacian tribes. The dragon does not seem to have been a native emblem with the Romans, and when they ultimately adopted it as a sort of subordinate symbol, the eagle still holding the first place, it seems to have been in consequence of their intercourse with other nations. Among all the new races which overran Europe at the termination of the classical period the dragon seems to have occupied nearly the same place that it held in the earlier stages of Oriental and Greek life. In the *Nibelungenlied* we find Siegfried killing a dragon at Worms; and the contest of Beowulf (q.v.), first with the monster Grendel and then with the dragon, forms the principal incident in the curious epic which bears the name of the former. Even Thor himself was a slayer of dragons. Among the Teutonic tribes which settled in England it was from the first depicted on their shields and banners, as it was also in Germany. Nor was the dragon peculiar to the Teutonic races. Among the Celts it was the emblem of sovereignty and as such borne as the sovereign's crest. Tennyson's *Idylls* have made every one familiar with "the dragon of the great pendragonship," blazing on Arthur's helmet, as he rode forth to his last battle and "making all the night a stream of fire."

Christianity inherited the Oriental idea of the dragon, which is made the emblem and embodiment of the devil. In St. John's Apocalypse—in fact, in all apocalyptic literature—it plays an important part. That Christ should "tread on the lion and the dragon" was an idea handed down from the Old Testament. In later Christian traditions St. Michael is the chief opponent of the infernal, and St. George of the terrestrial, dragon. The dragon in a cave on Mount Soracte represented paganism, and his defeat by Pope Sylvester symbolized the triumph of Christianity under Constantine. In Christian art the dragon is the emblem of sin, the usual form given to it being that of a winged crocodile. It is often represented as crushed under the feet of saints and martyrs. Sometimes its prostrate attitude signifies the triumph of Christianity over paganism, as in pictures of St. George and St. Sylvester; or over heresy and schism, as when it was adopted as the emblem of the knights of the Order of the Dragon in Hungary, an order instituted for the purpose of contending against the Hussites of Bohemia.

The dragon is often employed in heraldry; and other animals, such as the lion, are sometimes represented with the hinder parts resembling dragons. Consult Mähly, *Die Schlange in der Kunst* (Basel, 1867). See GRIFFIN.

DRAGON. The name now applied to various lizards. One is a South American tree lizard (*Thorictis drachena*), both eggs and flesh of

which are eaten. Others are members of the iguanid genus *Callisaurus*, several species of which are common in southern California and southward. The name most commonly belongs, however, to the arboreal flying lizards of the genus *Draco* of the East Indies. They are distinguished from all the other living lizards by having horizontally spread-out folds of skin, supported by five or six false ribs, which do not encircle the body, but stand out at right angles from it, forming a parachute, which buoys up the lizard in its extremely swift bounds from limb to limb in pursuit of insects, for it does not possess the power of true flight. It can scale long distances, resembling the flying squirrels in its method of aerial progression. When at rest, the ribs and skin are folded back along the sides of the body and do not interfere with active running about. About 20 species are recognized, none more than 8 inches long, but they keep in the tops of the forest trees, and little is known about them. The most familiar is the Malayan one (*Draco volans*), which is of a brilliant but variable metallic hue above, varied by bands and spots, while the parachute and the throat appendage of the male are orange. Similarly brilliant colors belong to the other species, yet little is seen of them, except when the creature is excited and displays itself in anger or courtship. The dragon has no power of changing its colors, is perfectly harmless, and is frequently kept as a tamed pet. See **PLATE OF LIZARDS**.

DRAGONADES. See **DRAGONNADES**.

DRAGON BIRD. 1. A name given to the umbrella bird (q.v.), in allusion to the shape of its crest, which resembles the ornamental top of the helmet of a dragon of the eighteenth century. 2. An Australian ant thrush (*Pitta strepitans*).

DRAGONET (OF. *dragonet*, diminutive of *dragon*, dragon). A fish of a genus (*Callionymus*) usually classed with the gobies, but by some authors given separate family rank. They are remarkable for having the gill openings reduced to a small hole on each side of the nape, and the ventral fins placed under the throat, separate, and larger than the pectorals. They have no air bladder. The species are pretty numerous, mainly inhabitants of the temperate coasts of the Old World, but some living in Oriental tropical seas, and of brilliant and quaint appearance. The sexes differ greatly, the adult males having the fin rays produced into filaments, and the intervening membranes highly colored, especially in the breeding season, whereas the females wear a more sombre dress. Hence the beautiful British species, the gemmeous dragonet, or yellow sculpin (*Callionymus lyra*), was formerly considered two species, one of which was finally discovered to be the female of the other. They feed upon small shellfish.

DRAGONETTI, drá'gò-nét'té. DOMENICO (1763-1846). A noted Italian double-bass player, born in Venice. He studied double-bass playing under Berini, a member of the band at San Marco, was admitted to the orchestra of the Opera Bouffe in 1768 and in 1769 to that of the Opera Seria. In 1773 he succeeded Berini at San Marco. He went to London in 1794, at once gained fame, and thenceforth resided chiefly in England. He was in 1808-09 in Vienna, where he had also visited his friend Haydn in 1798. His title of "patriarca del contrabasso" was not merely honorary; for in 1845, at the age of 82,

he headed the 13 double basses at the Beethoven festival in Bonn and won high commendation from Berlioz. As a performer, he has probably never been excelled. His instrument, a Da Salò, bought at the San Pietro Monastery, Vicenza, he presented to the vestry of San Marco, and to the British Museum he gave 182 bound volumes of the scores of classical operas. He published little.

DRAGON FISH. One of several small gurnard-like fishes of the genus *Pegasus*, inhabiting Oriental and Australian seas. Its body is covered with bony plates, which are movable except near the tail; and the pectoral fins are large and fanlike. The eyes are very prominent, and the snout greatly prolonged and toothless. A common Indian species is *Pegasus draco*, and another species (*Pegasus volans*) is frequently seen dried as a curiosity or serving as an ornament on boxes, etc., made in China. Little is known of their habits.

DRAGON FLY. Any amphibious insect of the order Odonata. These insects possess numerous popular names, such as snake feeder, horse stinger, spindle, devil's darning needle, and mosquito hawk. They have very large heads, due to the excessive size of the eyes; the antennæ are short, and the biting mouth parts are powerful; the four wings are of similar size and structure; the legs are long and used for perching rather than for crawling. Two distinct types of dragon flies are now recognized: (1) Zygoptera, whose wings in repose are held upright; and (2) Anisoptera, whose wings are held horizontal. To the former group belong our common slender-bodied blue forms sometimes called damsel flies, while to the latter belong our larger and usually more sombre species. Both kinds are most frequently found about ponds, marshes, or streams, but some forms go a considerable distance from water, in meadows, in sunny hours, where they hawk for small insects with exceeding speed and voracity. The Zygoptera fly nearer the ground and more among vegetation than do the Anisoptera. Dragon flies are known to swarm, both in America and in Europe, but the causes of these migrations are unknown. Although harmless, these insects are much feared by persons unacquainted with them, which explains some of the strange names and accounts for the quaint beliefs that exist among the country people, who say that if a "darning needle" gets into your hair most disagreeable things will happen, the least of which is the sewing up of the ears. The folklore of Europe, the Orient, and Japan abounds in superstitions and sayings in regard to these quite innocent but fierce-looking insects.

The reproductive habits of dragon flies are unique in that there is no direct transference of the sperm from the genital ducts to the female, as in other insects. The sperm, previous to the transference, is stored in an accessory receptacle near the base of the male abdomen. The clasping attitudes are also peculiar. The male grasps the neck of the female by means of a pair of forceps at the end of the abdomen, the female then bends forward the apex of her abdomen to the accessory sperm receptacle near the base of the male's abdomen, and thus the actual transference of the sperm takes place. Among the Zygoptera the pairs often fly about tandem-like, the male-clasping the neck of the female; and in some species the male may even retain his hold and accompany her when the female crawls be-

neath the surface to oviposit. The females which go beneath the surface are those which oviposit in the tissues of plants. In some dragon flies the eggs are dropped or washed off of the abdomen by dipping it into the water or striking it upon the surface. Larvæ of Odonata are called "nymphs" and are aquatic and carnivorous. The lower lip is greatly developed and forms a powerful grasping organ. The zygopteran nymphs have three platelike gills at the end of the abdomen, while in the anisopteran nymphs respiration takes place in the greatly modified posterior part of the intestine, into which water is drawn, and may be expelled with force sufficient to aid in locomotion. In the zygopteran genera *Euphaea* and *Anisoptera* the nymphs also possess, in addition to the terminal gills, lateral abdominal gills. Certain kinds of nymphs show decided preferences for certain habitats—some choosing standing water, others small streams, and still others rapid water. These preferences are as marked as in the case of the particular places frequented by the adults.

When a nymph is fully grown, it crawls out of water and attaches itself, by means of its claws, to some support. The nymph skin then splits along the top of the head and down the back, and through this rupture the imago escapes. At first the body and wings are limp and contracted, and only gradually expand to their full size; but the adult colors do not appear for several hours, or even days, after emergence. The duration of the life of the imago varies from about three to six weeks for many forms, but in the case of those few forms which hibernate the limit may even extend over six months.

While the dragon fly, on account of its preying upon small insects and mosquitoes, is considered beneficial, the nymphs, on the other hand, have been credited with destroying young fish in hatcheries. While small insects doubtless form the bulk of their food, the larger species do not hesitate to attack even wasps and butterflies.

The greatest extremes in size are found among the slender-bodied Zygoptera. The smallest is a Javanese species (*Agrioenemis minima*), whose abdomen is about $\frac{1}{2}$ inch long, and the largest is *Megaloprepus caerulatus*, from Central America, whose abdomen is about 4 inches long. A very large anisopteran (*Gynacantha plagiata*), from Borneo and Sumatra, has an abdomen nearly equal to the latter in length.

The damselflies are slender-bodied, delicate-winged forms, usually showing spots of brilliant color. The red-spotted (*Petersonia americana*), the black-wing (*Calopteryx maculata*), and the green-bodied (*Lestes eurina*) are among the most common in the eastern United States.

The amber-wing dragon fly (*Perithemis domitia*) shows very decided sexual differences—the female having clear wings with two pairs of irregular amber bands, while the wings of the male are wholly amber yellow. Among our most abundant large dragon flies are the banded (*Libellula semifasciata*) and the basal (*Libellula basalis*), both common about our ponds and streams throughout the summer months. All of these forms are figured on the Colored Plate.

About 2000 species of Odonata are known, the most of which are from tropical countries; but about 300 species occur in North America. Consult Miall, *Natural History of Aquatic Insects* (London, 1903), and Felt and Needham, "Aqua-

tic Insects of New York State," *Bulletin* 68, *New York State Museum* (Albany, 1903).

Fossil dragon flies, of which at least 75 species have been described, appear first in the Lias, where they present already a considerable differentiation, the majority of subfamilies being represented in the rocks of that period. In the Jurassic limestones of Solenhofen, Bavaria, occur numerous examples, mostly of extinct genera, that are often preserved in the finest manner, with the wings spread out. Dragon flies are also found in all the Tertiary insect-bearing beds, and the larvæ and pupæ occur in great abundance at Oeningen, Germany. See NEUROPTERA. See DAMSEL FLY and Plate of DRAGON FLIES.

DRAGON LEECH. See LEECH.

DRAGONNADES', or DRAGONADES (Fr., from *dragon*, dragoon, so called either from their firearm, which was ornamented with the head of a dragon, or from their standard, which bore a dragon). The name applied to a series of religious persecutions in France, which was inaugurated shortly before the revocation of the Edict of Nantes (1685) and continued for some time. Louis XIV's Minister of War, the Duc de Louvois, was responsible for the cruel measures taken to compel the Protestants to renounce their faith and enter the Roman church. Armed expeditions marched through the provinces demanding of the Huguenots (q.v.) in the small towns and villages that they should abjure their faith. Foremost among the armed force rode dragoons, who, on account of their barbarity, had the unenviable honor of giving a name to the persecutions. It was the custom to quarter the dragoons in the houses of those Huguenots who showed themselves particularly obstinate in denying the doctrines of Catholicism. The outrages committed by a brutal soldiery, free from all restraint and, in fact, encouraged in their licentious conduct, made life not only impossible for the Huguenots and drove thousands of families out of the country or into the bosom of the church. Louis was delighted to find that from 250 to 400 Protestants were being converted daily, and in consequence, on Oct. 22, 1685, a few months after the date of the first of the persecutions, he revoked the Edict of Nantes (q.v.), that the good work might be fully accomplished. Under Louis XV the dragonnades were renewed by the chief minister, the Duc de Bourbon. Consult: Rousset, *Histoire de Louvois* (4 vols., Paris, 1863); Tylor, *The Huguenots in the Seventeenth Century* (London, 1892); Perkins, *France under the Regency* (Boston, 1892); Baird, *The Huguenots and the Revocation of the Edict of Nantes* (New York, 1895).

DRAGON OF WANTLEY, THE. A ballad, apparently a parody on the old romances, which appears in Percy's *Reliques*. The dragon, who lives in a well, is killed by the hero, More of More Hall, clad in a suit of spiked armor.

DRAGON'S BLOOD (so called on account of the color), or GUM DRAGON. An astringent resinous substance obtained from several trees of different natural orders, growing in warm countries. The greater part of the dragon's blood of commerce is produced by the *Calamus draco*, growing in the East Indies, the resin being attached in the form of hard, brittle masses to the fruits of the tree. Two varieties of dragon's blood occur in commerce. One variety is brought in the form of sticks, the other in the form of cakes. The separation of the resin from

the fruits is effected either by shaking the latter in large bags or by boiling them in water.

American dragon's blood is derived from the *Pterocarpus draco*, and similar resins are produced by the *Dracena draco*, the *Croton draco*, and the *Eucalyptus resinifera*. True dragon's blood is a colorless and tasteless substance melting above 80° C.; American dragon's blood is opaque, of a deep reddish brown color, brittle, smooth, with a shining shell-like fracture, and when burned emits an odor resembling that of benzoin. It is nearly insoluble in water, but is soluble in alcohol, benzene, carbon disulphide, and many oils. It was formerly used in medicine; at present, however, it is employed in the preparation of varnishes and lacquers and in photo-engraving processes.

DRAGON'S MOUTH (Sp. *Boca del Drago*). A short strait on the coast of Venezuela, South America, which connects the Gulf of Paria with the Atlantic and separates the north end of the island of Trinidad, on the east, from the Paria peninsula on the west (Map: West Indies, G 5).

DRAGON TREE. See *DRACENA DRACO*.

DRAGOON. A soldier trained to fight either on foot or on horseback. The name has been derived, by different authorities, either from the dragon emblazoned on the standard carried by such troops, or from the dragon's head on the muzzle of the short musket formerly carried by dragoons. Since the time of Frederick the Great the name has been used, generally, to designate a class of cavalry between heavy and light cavalry. Formerly some of the mounted regiments of the United States army were known as dragoons. The term is no longer used. In England the Scots Greys (organized 1683) is the oldest dragoon regiment. See *CAVALRY*; *MOUNTED INFANTRY*.

DRAGOMIS, STEPHAN (1842-). A Greek statesman, born in Athens. He studied in Athens and Paris and in 1879 was elected to the Lower House of the Greek Parliament. In 1886-90 and in 1892 he was Foreign Minister. He formed a cabinet in February, 1910, which survived until October, succeeded in calming the Military League and in convoking a National Assembly, and opposed the movement to side openly with the Thessalians against Turkey. In 1912 he was sent to take over the government of Crete.

DRAGUIGNAN, *dra-guig'nan*. The capital town of the Department of Var, France, on the Nartuby, a tributary of the Var, 40 miles northeast of Toulon (Map: France, L 5). It is situated in a valley surrounded by hills, the slopes of which are covered with vineyards and olive plantations. Its principal buildings are the prefecture, the courthouse, a hospital, and a museum containing pictures by Rembrandt, Teniers, and Panini, a zoölogical garden, and a public library of 25,000 volumes. It has manufactures of coarse woollens, leather, hosiery, silks, soap, brandy, lumber, oil, and earthenware. Pop., 1901, 9671; 1911, 9974. The town was founded in the fifth century. Claude Gay the botanist was born here in 1800. During the Middle Ages it was strongly fortified. The fortifications were destroyed in the civil wars, but were reconstructed in 1615. It replaced Toulon as the capital of the department in 1793.

DRAINAGE. In law, a right to discharge surface water from one's land upon the land of another. The civil law of Rome recognized a natural right of drainage as between adjacent lands of different elevations, the rights of the owners of such lands being governed by the

law of nature. By that law, which has been adopted in Pennsylvania, Illinois, California, and Louisiana, the lower proprietor is bound to receive the surface waters which naturally flow from the estate above, provided the servitude has not been increased by the acts of the upper proprietor.

No such right exists by the common law, and it is held in most of the United States, as well as in England, that the lower proprietor may lawfully obstruct the flow of surface water upon his land from that of his neighbor, though the latter is not liable for any damage which may result from the natural flow of such water upon the lands of the former. In both systems of law, however, a riparian proprietor may drain his land into a natural watercourse which flows over or by his land, and no obstruction of the stream by the lower proprietor which prevents such drainage will be permitted. This is a natural, as distinguished from an acquired, right of the riparian proprietor, and is therefore strictly analogous to the natural servitude of drainage of the civil law above alluded to. It exists *ex jure nature* and is incapable of alienation, of release, or of severance from the land.

Apart from this limited natural right of drainage, the common law recognizes also an easement of drainage, which may be acquired by grant or prescription over the land of another. This may exist with or without an artificial construction and may be superficial or subterranean. The common-law right of *cave dropping* is one form of this easement, though its usual form is the right to construct and maintain an artificial drain and to discharge water through the same into and through the adjoining premises. The familiar right of the householder in a city or village to discharge water into a public or municipal drain is of this nature. The right is violated by any interference or obstruction caused by the owner of the lower or "servient" estate, whether intentional or not, and may be enforced by an action for damages or by injunction to prevent a threatened or continued interference. The easement carries with it the right to enter on the premises affected by it in order to repair the drain and keep it open; but it is, like other easements, carefully restricted to the amount and kind of user included in the terms of the grant. See *EASEMENT*; *SERVITUDE*; *WATERCOURSE*; and the authorities there referred to.

DRAINAGE (from *drain*, AS. *dreahnian*, *dreahnian*, *drénian*, Icel. *dragna*, from AS. Goth. *dragan*, Icel. *draga*, OHG. *tragen*, Ger. *tragen*, Eng. *draw*, *drag*). The removal of surplus water from the soil by means of canals, open ditches, and drains, or other conduits which are either porous or else laid with open joints. In its larger sense the term "drainage" applies to the reclamation of extensive areas of land either under water or in the condition of marsh or swamp, and consequently unfit for habitation or cultivation. In agriculture drainage implies the removal of surface or subsoil water from a more limited area which it is desired to put under specific cultivation, and generally is understood to involve the use of tile drains, as will be described below. The name "drainage" is also used to denote a system of sewerage for the removal of liquid household wastes as well as the surface and subsoil water of towns and cities. This aspect of the subject will be found treated fully under the head of *SEWERAGE AND DRAINAGE*.

Reclamation of Land. In reclaiming large

tracts of land, often of great fertility, but which are at so slight an elevation above the sea or the neighboring streams that they can be rendered fit for cultivation and habitation by artificial means only, dikes or embankments are constructed to keep out the flood waters, and a system of canals built to collect and carry off the superfluous water. In the case of marsh lands the method employed depends upon the elevation and conformation of the land to be drained, but all lands may be divided into two classes—those that can be drained by gravity, and those in which the water must be pumped out, either all or a part of the time. Many coast lands are so low that the water will run off only at low tide, and such lands are protected from high tide by embankments. The water is gathered by a network of subsidiary ditches into a few main drains, which carry their contents into the sea at low tide. The tidal flow is kept out by automatic doors or sluices. The problem of draining low lands by gravity is an increasingly difficult one, because a section that is drained tends to sink, through shrinkage, below its former level. Hence it happens that land which at first was drained by gravity afterward, through subsidence, requires pumping to carry off the water. Much of the land that has been most successfully reclaimed from encroaching waters has been so low that it required pumping to carry the drainage off during a whole or a part of the year. This is particularly true in Holland. Many other considerations, besides the actual level of the land to be drained, must be taken into account in devising a system of drainage for low lands. The object sought in laying out drains in a flat country is to provide channels of the least possible area, depth, and inclination that will suffice to carry off the water properly. Every increase beyond this point is a waste of land and of expense in excavation; and where pumping is necessary, the greater the inclination or grade of the canal, the higher will be the lift. Usually a much greater area must be devoted to ditches when the land is drained by gravity than by pumping, so that the increased expense for constructing and maintaining ditches will sometimes equal the cost of installing and operating pumps.

In determining the number and capacity of drains required, the local rainfall and the absorbent power of the soil must be taken into account. Low areas, surrounded by higher land, often have not only the rainfall on their own area, but also the drainage from the surrounding country to be provided for. This is prevented, whenever practicable, by separating the low land from the surrounding country by a catch drain (q.v.). Care should be taken that the subsidiary ditches or drain pipes do not discharge into the main canal at a point below the water level of the latter, for, if this happens, the free circulation of air through the soil by means of the drains is impeded, and there is danger that the water will back up. Drainage canals should be kept free from weeds, for their growth impedes the flow of water by decreasing the area of the ditch and by increasing the friction of the running water. Various machines have been devised for cutting the growth of weeds in ditches and for digging them out by the roots. Having considered some of the most general principles underlying the construction of a drainage system, a few of the most important examples of land reclamation will be described.

One of the best-known and most extensive systems of land reclamation is found in Holland. Here the greater part of the country is low and flat and is protected from inundation by an enormous system of dikes. The soil was originally marshy, and the territory included numerous lakes. By an elaborate and scientific system of canals many of these marshes and lakes, now called *polder-land*, have been drained and converted into fertile soil. (See *POLDER*.) The most famous of these polders is the former site of the Haarlem Lake, where a population of nearly 20,000 people are now dwelling. Another of these polders is the Biesbosch.

The Haarlem Meer was formed in the sixteenth and seventeenth centuries by the junction of several small lakes. Three villages were covered with water, the last in 1647, and much otherwise valuable territory was rendered useless. Of the various early plans for relief, one proposed by Leeghwater in 1643 contemplated an embankment around the whole area, and 160 windmill-driven pumps, with an estimated cost of about \$1,500,000. In 1836 the Meer was extended still further, and in 1837 work was begun for the reclamation of 44,724 acres of land, covered with some 13 feet of water. An embankment $37\frac{1}{2}$ miles long was built around the lake, and a canal then in existence was improved and extended, partly for navigation. It was decided to use steam power for pumping; three engines were erected for that purpose.

The first engine lowered the lake 6 inches in about 10 months, after which it took the three engines 39 months to complete the work. Ditches within the lake bed were then built, the main ditches leading to the pumps. About 750 miles of ditches were dug. The cost of the project was about \$5,500,000.

The Zuyder Zee forms an arm of the North Sea, and was created in the year 1170 by a severe storm breaking down the sand dunes along the coast and inundating the land for a distance of 60 miles.

Previous to the year 1892 a commission was appointed to investigate a project for draining the Zuyder Zee. Favorable reports were presented by the commission in 1894 and 1897, and in 1900 a bill providing for the work was introduced in the States-General, but it was withdrawn in 1901. Apparently it was decided to concentrate efforts, for a time at least, to one of the areas named below.

It was proposed to inclose the inner part of the Zuyder Zee by an embankment, 18 miles long and as many feet high, from Wierengen to Piaam, with four other inclosing banks to inclose as many areas which were to be pumped dry. This would leave an inland sea of 560 square miles surrounding these areas and cut off from the North Sea by the above-mentioned dike, whose elevation would be lower than that of the exterior water. The Yessel River would empty into this, and the inland lake in turn would empty by sluices through the dike into the North Sea. The estimated cost of the completed plans was about \$79,000,000, and it was expected to take 33 years to complete. The area thus reclaimed would be about 480,000 acres, with a net renting value of \$10 an acre, giving a revenue of \$316,000 a year after paying interest and principal.

The Fens is a large tract of flat and marshy land on the east coast of England. The whole region was, centuries ago, converted into an un-

profitable marsh by repeated incursions of the sea, coupled with obstructions to the outward flow of the rivers Nene, Cam, Ouse, Welland, etc. Vast operations have been carried on ever since the time of Charles I by digging new channels and outfalls and employing windmills and steam engines to pump the water from the marshes and ponds into these artificial channels. Early in 1914 it was reported that the Fens drainage works served two districts of 30,000 and 2000 acres respectively, administered by two "trusts." For the larger trust two centrifugal pumps, each driven by a 50-horsepower Diesel oil engine, were to be installed to supplement the old scoop water wheels, 20 feet in diameter, which lift water 4 feet to the canal. These wheels were first driven by beam engines of 60 and 80 horsepower each, built in 1825 and rebuilt in 1883. The smaller trust had already replaced its beam engine by a 50-horsepower Tange gas engine and suction gas-producer plant, belted to the old 18-foot water wheel, which lifts water 3 feet. These pumping plants are operated in wet seasons only.

In the valley of the Po, by the end of the nineteenth century some 600,000 acres of marsh land had been drained and transformed into rich farmland, the water being lifted off by pumps. To extend this work the Italian government appropriated \$40,000,000, to be spent from 1900 to 1933, under an act requiring local governments and individual property owners to spend two-thirds that amount for the same general purpose. The same kind of work has been done in the south of France. In the delta of Lower Egypt work was begun in 1912 by the government to reclaim 973,500 acres of land at an estimated cost of \$12,500,000. Four years was allowed for the work.

In America a large amount of land has been reclaimed by gravity canals and ditches in the Central West, the South, and Southwest, particularly in Illinois, Indiana, Minnesota, Florida, Louisiana, Arkansas, and Missouri.

The Florida Everglades present a great and interesting opportunity for drainage, and considerable has been accomplished there by both the State and private companies. The Everglades occupy an area of about 4000 square miles in southern Florida, beyond Lake Okeechobee. They are in effect an immense marsh, the lands of which, on being drained, are very fertile. An important engineering report on the drainage of the Everglades was made in 1912 by Daniel W. Mead, of Chicago, Allen Hazen, of New York, and Leonard Metcalf, of Boston, in behalf of private land interests. They concluded that the system of canals built and proposed by the State of Florida "is entirely inadequate for the drainage of the Everglades" and that these canals would actually contribute to the flooding of the land by affording a ready passage thereto of the waters of Lake Okeechobee when the lake level is high. The first problem, they declared, was the control of the lake so as to prevent flooding the Everglades and so as to store its waters for purposes of irrigation at other than flood seasons. The next problem was the drainage of the Everglades. Each problem could best be solved by building canals. Careful study of the problem was advised.

A second engineering report on draining the Everglades was made public early in 1914. This report was by Isham Randolph, of Chicago, Marshall O. Leighton, of Washington, and Edmund T. Perkins, of Chicago, and was made to

the commissioners of the Everglades Drainage District and the trustees of the Internal Improvement Fund of the State of Florida. The commission advised lowering the level of Lake Okeechobee and taking care of waters coming to the lake from the north by providing a canal 24 miles long from the lake to the St. Lucie River and Atlantic Ocean. Besides lowering the lake, this canal would form a navigable waterway and would also make possible the development of 5000 horsepower, which would be particularly valuable in a section without mineral fuel. The estimated cost of a canal 24 miles long, 200 feet wide on the bottom, with a 12-foot water depth, was \$2,259,000, includ-

ing locks and dam. The lake-control canal would lessen the burden resting on the land-drainage canals, but it would still be necessary to build three canals to the Atlantic Ocean at an early date (in addition to the four already built or under construction or contract by the State). Later on, additional canals would be advisable, some leading to the Atlantic Ocean and some to the Gulf of Mexico. Nine short canals were also recommended for draining the area bordering on Lake Okeechobee, these to discharge into the lake itself. The estimated cost of the three new land-drainage canals to be built at once and of enlarging the canals already built or under way was \$4,281,000. This would provide 391 miles of canals and drain

2095 square miles, as compared with the 255 miles of canals draining 1084 acres of land now built or being built. The canals advised for future construction, as land sales and utilization demand, aggregate 428 miles in length, would drain 3504 acres, and were estimated to cost \$15,866,000. The grand total of all the work recommended involves an estimated expenditure of \$22,406,000, for the ultimate drainage of 5599 square miles of land, besides navigation and water-power improvements. It should be added that the canals already built or under construction also make provision for navigation. For abstracts of the lengthy reports here briefly outlined, consult the *Engineering News*, Oct. 23, 1913, and Jan. 15, 1914, from which latter issue the accompanying map is reproduced.

Mosquito-reduction campaigns have led to the drainage of many large and small areas of land in various parts of the world since the establishment of the relationship of these insects to malaria and yellow fever at the close of the nineteenth century, and since it was learned that the mosquito pest in general could be reduced in the same way. Besides the work of this kind along the Panama Canal, probably the most notable example is afforded by the work done by the State of New Jersey, beginning in 1904. Thousands of acres of meadow land have been drained by hundreds of thousands of feet of ditch since the work was begun. The work has been carried out under the direction of the State entomologist. Novel and efficient ditching machines have been employed.

Drainage, strangely enough, often has to be followed by extensive drainage works, to prevent the land from becoming marshy or from being ruined by a fall in the water level.

Drainage of Farm Lands. The works already described are for the main drainage of large areas. They leave for the individual farmer the task of removing surface water from

freeing land from superfluous water was by open ditches and drains, but throwing up the land in beds, hilling, and ridging were practiced with the same object in view. These, however, are only partial and superficial in their effects. The Roman agricultural writers mention the good results arising from covered drains, which were formed of stone, wood, or other substances. Cato, who wrote in the second century B.C., gave specific directions for drainage. The art of drainage was understood and practiced at a much earlier date by the Egyptians and Babylonians. Primitive methods were also practiced to a limited extent in early days in Great Britain and on the continent of Europe. The progress of draining, however, was slow and partial until well on in the nineteenth century, when the practice was reduced to a system.

The use of drain tile in France is said to have begun many centuries ago, but to have become a lost art. Drain tiles were first used in England in 1790, according to Elliott. Their use spread rapidly in England and Scotland after 1840 and soon came to France and Germany. In the United States John Johnston introduced handmade tile on his farm at Geneva, N. Y., in 1835, and, "by 1851 he had laid 15 miles of drains with most gratifying results" (Elliott). The first drain-tile machine was imported from England to the United States in 1848. The most efficient system of drains can be laid out only after careful leveling (q.v.) of the land to be drained. The smaller drains usually open into larger or main drains, which are laid in the lowest ground, instead of each discharging its quota of water into an open ditch. This is rendered necessary, as the mouths of the smaller drains would be more liable to be choked up by the growth of weeds; while the collecting of water into main drains secures a fuller flow to sweep out any matter which might accumulate where the discharge is small. Moreover, the less the action of the air in the drains, the more efficient they are. The most efficient and at the same time the cheapest ditch is made so that a pipe of cylindrical form may be laid along its bottom, which need be of no greater width than is necessary to allow of the pipes being properly laid. Ditches of this form are cut with a set of spades, which are of different widths—the broader implements being used for taking out the top, and the narrower for the

FINISHING TOOLS.

1, groove maker for round tile, operated by pushing; 2 and 4, the same for hexagonal tile; 3, groove maker for round tile, operated by drawing.

No. 1, long-handled shovel for loose earth; 2, 3, 4, spades for digging the ditch.

his own land to the main ditches or of lowering the ground-water level to increase the productivity of the soil. The earliest method of

bottom. The implement which prepares the bottom of the ditch for the tile is called a draining scoop, of which there are a variety of forms. Various forms of machines adapted to digging ditches for drains are found in the market. Before the general use of pipes stones were the common materials with which drains were formed. It was recommended that they should be broken so as to pass through a ring $2\frac{1}{2}$ inches in diameter. From 9 inches to 1 foot in depth was the quantity which was commonly put in. When tiles and pipes were first used, it was even thought necessary to have some gravel, or small stones, placed above them in the drains, for the purpose of enabling the water to find its way into them. It was soon found, however, that tile drains were quite as efficient without any stones or gravel. Many kinds of tiles and pipes have been tried, but the cylindrical form is most used. At one time a bore of 1-inch diameter in the tile was thought sufficient, but tiles of 3 to 4 inches are now preferred. They are usually made 12 or 15 inches in length. The continuity of the drain is sometimes maintained by collars, but these are expensive and are not considered necessary. In soft or clayey subsoil semicylindrical tiles have been laid with the bend up, but this is rarely, if ever, necessary. The size of the tile required depends on the size of the area to be drained. Concrete tiles have come rapidly into use since about 1900 and when properly made, as they may readily be, give satisfaction.

CROSS SECTION OF DRAIN,
Showing tile in place.

There is much difference of opinion as to the proper depth and distance apart of drains. Smith, an early worker in this field, at first advocated placing the drains from $2\frac{1}{2}$ to 3 feet deep, and at intervals of from 10 to 40 feet according to the nature of the land. Experience, however, has been gradually favoring deeper drains, beyond the reach of plant roots and at wider intervals. Even on the most tenacious soils, with subsoils of till, few now think of having drains less than 3 feet in depth, though the distance apart should not in many cases be more than from 25 to 30 feet. The depth, however, depends greatly on the soil— $3\frac{1}{2}$ and 4 feet, with the leader drains 6 inches deeper, are common dimensions. In peaty land the depth has sometimes to be 7 feet. The width between drains depends on the wetness of the land and the character of the subsoil. King states that

"in loose, loamy soils, and especially if underlain by sand, good drainage will be secured with drains 100 feet apart and $3\frac{1}{2}$ feet deep. On heavier soil they must be closer." The following table, given by Parkes, may be studied with profit in this connection:

MASS OF SOIL DRAINED FOR DIFFERENT DEPTHS
AND DETAILS OF TILE

Depth of drains	Distance between drains	Mass of soil drained per acre
<i>Feet</i>	<i>Feet</i>	<i>Cubic yards</i>
2	24	3,226½
3	33½	4,840
4	50	6,453

The principal advantages of drainage of ordinary farm lands are: (1) the removal of stagnant water, the presence of which favors the formation of chemical compounds injurious to crops, keeps the land cold by evaporation, and delays not only plowing, planting, and subsequent tillage operations, but harvesting; (2) the deepening of the surface stratum of friable soil, with the consequent increase of feeding ground for the roots of plants, and the increased capacity of the soil to absorb rains and manures and to retain them and also capillary water during the summer. Drainage is also one of the most efficient means of removing excess of soluble salts from alkali soils (q.v.) and thus rendering them fit for the growth of useful crops. Subsoil drainage has been perhaps the most valuable improvement connected with agriculture. Consult: Wheeler, *The Drainage of Fens and Lowlands by Gravitation and Steam Power* (London, 1888); King, *Irrigation and Drainage* (New York, 1899); Elliott, *Engineering for Land Drainage* (New York, 2d ed., 1912); id., *Practical Farm Drainage* (ib., 2d ed., 1908). See SWAMP; SAVANNAS; BOG; ALKALI SOIL.

DRAINAGE. For the use of this term in physiography, see RIVER; VALLEY; GEOLOGY.

DRAINAGE TUBES. In surgery, tubes of rubber or glass employed for removing pus or septic matter from tissues or from cavities. The rubber drainage tubes are the ones most frequently used. They are of soft rubber, from $\frac{1}{8}$ to $\frac{1}{2}$ an inch in diameter, and from a few inches to 7 or 8 inches in length, or even longer, and are perforated by numerous holes, from $\frac{1}{8}$ to $\frac{1}{4}$ of an inch in diameter, throughout their length. The glass tubes are used mainly for abdominal work and are of large diameter, usually from $\frac{3}{8}$ to $\frac{5}{8}$ of an inch. For special purposes tubes of metal and hard rubber have been employed. When placed in fresh wounds, or in the body cavities after operation, when suppuration is absent, their object is to remove blood, serum, or discharges which by their subsequent accumulation might become a source of septic infection. Drainage tubes were first introduced by the distinguished French surgeon Chassaignac.

DRAIN GAUGE. See LYSIMETER.

DRAISINE. An early form of velocipede. See BICYCLE.

DRAKE, ALEXANDER WILSON (1843—). An American artist and critic, born at Westfield, N. J. He studied oil and water-color painting and practiced wood engraving. From 1870 to 1881 he was director of the art depart-

ment of *Scribner's Magazine*, and thereafter he held a similar position on the *Century* and *St. Nicholas*. In this capacity he did much to aid the development of the new school of wood engraving in America. He was also identified with other important art movements in the United States.

DRAKE, CHARLES DANIEL (1811-92). An American jurist, born in Cincinnati. He served for some years in the United States navy, then studied and practiced law in his native city, and afterward went to St. Louis, where he was a member of the Missouri Constitutional Convention of 1865. From 1867 to 1870 he was a member of the United States Senate and from 1870 to 1885 was Chief Justice of the Court of Claims in Washington. He published a *Treatise on the Law of Suits by Attachment in the United States* (1854) and *Union and Anti-Slavery Speeches* (1864).

DRAKE, DANIEL (1785-1852). An American physician. He was born in Plainfield, N. J., graduated in the medical school of the University of Pennsylvania in 1815, and settled in Cincinnati, Ohio, where he became known as a physician and writer. In 1820 he organized the Medical College of Ohio in Cincinnati and secured a State appropriation for its support and that of a hospital. In 1827 he founded the *Western Journal of the Medical and Physical Sciences*, which he continued to edit until 1848. He was connected, either as a lecturer or professor, at different times, with Transylvania University, Lexington, Ky., the University of Louisville, and Jefferson Medical College, Philadelphia. His voluminous published works include: *Topography, Climate, and Diseases of Cincinnati* (1810); *Notices Concerning Cincinnati* (1810; 1908); *Practical Treatise on the History, Prevention, and Treatment of Epidemic Cholera* (1832); *Practical Essays on Medical Education* (1832); *Systematic Treatise on the Principal Diseases of the Interior Valley of North America* (1850-54); *Pioneer Life in Kentucky*, ed. by his son (1870). Consult *Mansfield, Life of Daniel Drake* (Cincinnati, 1855).

DRAKE, SIR FRANCIS (c.1545-96). An English admiral and navigator, born at Crowndale, near Tavistock, in Devonshire. He was apprenticed at an early age to a sea captain and later engaged in the coasting trade for a few years. In 1565-66 Drake extended the field of his operations to Guinea and the Spanish Main. In 1567-68 he commanded a ship in the last expedition of Hawkins against the Spaniards, which ended so disastrously. After this he made two voyages to the West Indies, undertaken for the purpose of obtaining information preparatory to the execution of a plan of revenge for Hawkins's ill-fated squadron. This done, Drake set out on a third voyage in 1572, having with him three ships and 73 men, and with this force captured the Spanish town of Nombre de Dios, on the Isthmus of Panama, with an enormous store of treasure, took a Spanish galleon in the harbor of Cartagena, and burned the town of Porto Bello. Finally, the indefatigable adventurer, with 18 Englishmen and 30 Indians, crossed the Isthmus of Panama and saw the South Sea, praying God that he "might sail once in an English ship in that sea." Laden with spoil, he sailed homeward, and reached Plymouth on Sunday, Aug. 9, 1573. From 1573 to 1576 Drake served in Ireland, but in the latter year his thoughts

turned to the sea, and in December, 1577, he sailed from Plymouth for the Spanish Main with a squadron consisting of his own ship, the *Pelican*, of 100 tons, the *Elizabeth*, of 80 tons, and three smaller vessels. That this expedition against a nominally friendly power was encouraged, if not sanctioned, by Queen Elizabeth, is undoubted. Drake sailed for South America, entered the Río de la Plata, and went south to the Strait of Magellan. After battling with the currents for 16 days he entered the Pacific. A furious storm separated the fleet. The *Elizabeth* returned to England, another vessel was lost with all on board, and the *Pelican*—renamed the *Golden Hind*—was alone left to explore the unknown Pacific. The voyage was a series of successful exploits. The Spanish towns on the coasts of Chile and Peru were sacked, and a treasure ship was captured. Drake then steered for the northeast, hoping to find a passage back to the Atlantic, but, finding his crew unwilling to encounter the cold of the high latitudes, he turned south and refitted his ships in a small harbor just north of the Golden Gate, receiving the homage of the natives in the name of Queen Elizabeth. He then steered across the Pacific, touched probably at what are the Pelew Islands and at Ternate, in the Moluccas, and after many hazardous experiences anchored off the southwest coast of Java on March 10, 1580. Thence he struck across the Indian Ocean, doubled the Cape of Good Hope on June 15, and finally arrived at Plymouth in late September, 1580, laden with treasure and spices. Queen Elizabeth sanctioned Drake's "reprisals," visited the *Golden Hind*, and knighted her bold commander.

Between 1581 and 1585 Drake was mayor of Plymouth, and during a part of the year 1585 and the whole of 1586 he commanded a fleet of 21 ships in a successful plundering expedition against the Spanish West Indies. From the West Indies and Florida Drake made his way up the coast to Virginia, whence he sailed for England, taking with him the disheartened Raleigh colonists whom he had found at Roanoke. It is said that he brought back to England on this voyage both the potato and the tobacco leaf. In the spring of 1587 Drake was sent with a fleet to raid the formidable Armada which Philip was collecting for the invasion of England. He entered the harbor of Cadiz, destroyed the fleet in the roadsteads (10,000 tons), secured much booty, and withdrew to plunder the coast towns, destroying ships and fortifications as he went. From the Spanish coast he sailed for the Azores in the hope of meeting any homeward-bound ships and was fortunate enough to secure a Portuguese East Indiaman with a precious cargo, the first intimation England had of the vast possibilities in the East India trade. He strongly urged the Queen and her ministers to follow up the blow already given Spain without allowing her time to recuperate, but the expedition in which he planned to repeat his Cadiz exploit was foiled by contrary winds. He returned to Plymouth and, on the arrival of the Spanish Armada, served as vice admiral under Lord Howard in the fighting which resulted in the defeat of the Spanish fleet. The story is told that he kept Lord Howard from putting to sea until they had finished their game of bowls, saying: "There's plenty of time to win the game and thrash the Spaniards too." The wreck of the

great Armada quieted all fears of invasion in England, and by way of reprisal a fleet was sent under Drake and Sir John Norreys to the coasts of Spain and Portugal in the spring of 1589. A large amount of booty was taken, and the enemy's stores and shipping were so effectually destroyed as to prevent all possibility of a future attempt against England. A few years of quiet were followed, in 1595, by an expedition to the West Indies. The Spaniards had received intelligence of the attempt, and the Englishmen were repulsed in an attack upon Porto Rico and other places. Drake died off Porto Bello, Jan. 28, 1596. Consult: Corbett, *Drake and the Tudor Navy* (London, 1898); id., *Sir Francis Drake*, in "English Men of Action Series" (ib., 1890). The intensely interesting original narrations of Drake's exploits may be found in the Hakluyt volumes (ib., 1848, 1850, and 1865); in Arber, *An English Garner*, No. 5 (7th ed., Birmingham, 1880-83); and in the *Camden Miscellany*, vol. v (London, 1863).

DRAKE, FRANCIS SAMUEL (1828-85). An American author, born at Northwood, N. H., the son of Samuel Gardner Drake. His most important work is his *Dictionary of American Biography* (1872), containing 10,000 biographies, nearly all prepared by himself. He also wrote: *Life of General Henry Knox* (1873); *The Town of Roxbury* (1878); *Indian History for Young Folks* (1884); and contributed to Winsor's *Memorial History of Boston* (1880-82).

DRAKE, drä'ke, FRIEDRICH JOHANN (1805-82). A German sculptor. He was born at Pymont, June 23, 1805, the son of a mechanic and served an apprenticeship in cabinetwork. His talent in clay modeling attracted the attention of Dr. Mundhenke, a relative of Rauch, who in 1827 obtained for him admission into the sculptor's atelier. Drake also studied (1836-37) in Italy where he came under the influence of Thorvaldsen, but Rauch was his principal master, and his first works were executed under Rauch's directions. The best of them is a group of a "Dying Warrior" (1833), crowned laurel of victory; a "Madonna and Child," bought by the King of Prussia; and a graceful statue of a "Female Vine Dresser" (Ministry of Justice). His early works also include a series of excellent portrait statuettes of Goethe, Schiller, Rauch, the two Humboldts, and other celebrities. In 1836 he modeled the colossal bronze statue of Justus Möser, a German patriot, for Osnabrück, and in 1844 he completed the plaster statues of the eight "Provinces of Prussia" for the White Hall in the Royal Palace of Berlin. Among his best works is the marble statue of Frederick William III in the Thiergarten, Berlin; the frieze crowning the circular pedestal, 18 feet in height, represents the enjoyment of nature and is one of the most graceful works of modern sculpture. Noteworthy among his other works is the noble marble statue of Christian Rauch, in the vestibule of the New Museum, Berlin; another of the sculptor Schinkel (1869), and a marble group on the Schlossbrücke representing a "Warrior Crowned by Victory" (1857). Perhaps the most important of all his monumental works is the colossal bronze statue of Emperor William I (1867), now on the new Hohenzollern Bridge at Coblenz. At the Paris exhibition of 1867, this monument was adjudged the most remarkable work of modern sculpture and brought to the sculptor the cross of the Legion

of Honor. His latest works include the "Victory" on the Siegessäule, Berlin, the colossal bronze statue of Alexander von Humboldt in Philadelphia, and busts of Bismarck and Von Moltke. Drake is one of the foremost representatives of the German school of sculpture of the nineteenth century. His art is manly and strong, and not without a high appreciation of beauty of form. But he never quite emancipated himself from the semiclassical influence of Rauch, whose lofty simplicity always remained his ideal. In his portrait work he renders the character of the subject in its most attractive features, but without idealization. He was highly regarded by contemporaries, having been professor of the Academy of Berlin and member of the academies in Munich, St. Petersburg, Antwerp, Rome, and Paris. He died in Berlin. Consult Lübke, *History of Sculpture*, vol. ii (London, 1872), and Heinrich, *Rauch, Rietschel und Drake* (Basel, 1884).

DRAKE, JOSEPH RODMAN (1795-1820). An American poet. He is chiefly remembered for his poems "The American Flag" and "The Culprit Fay," and for the eulogy by his friend Halleck (see HALLECK, FITZ-GREENE), beginning "Green be the turf above thee." Drake was born in New York City, was early left an orphan, and had a hard struggle in his first years. He managed, however, to study medicine, graduating in 1816, and the same year married the daughter of Henry Eckford, a shipbuilder, much to the bettering of his circumstances. The same year also he wrote "The Culprit Fay," his longest work, a fanciful poem which aimed to show that American rivers were not unadapted to romance and romantic treatment. In 1818 he went to Europe and on his return wrote a series of verse satires for the New York *Evening Post* on current events. They were done in conjunction with Halleck and are generally known as *The Croakers*. The verses were distinctly witty and very popular. In 1819 Drake went to New Orleans to recover his health, but the following year he died of consumption in New York. *The Culprit Fay and Other Poems* (including "The American Flag") was published in 1835. There have been two later editions. The *Croaker* verses were collected in 1860.

DRAKE, NATHAN (1766-1836). An English physician and author. He was born at York and was educated at Edinburgh University. After a short residence at Sudbury he removed, in 1792, to Hadleigh, Suffolk, where he became prominently known as a physician and essayist. He was a versatile and very prolific author. His more important works include: *Shakespeare and his Times* (1817), in which the accumulated material of previous editions and annotations was for the first time collated and presented in its entirety; and *On the Use of Digitalis in Consumption* (five papers published in the *Medical and Physical Journal*, London, 1799-1800). His *Literary Hours* (1798) were exceedingly popular early in the nineteenth century (4th ed., 1820).

DRAKE, SAMUEL ADAMS (1833-1905). An American editor and author, born in Boston. Upon the outbreak of the Civil War he became inspector and adjutant general of the Kansas militia and in 1864 brigadier general. He wrote *Around the Hub* (1891); *New England Legend and Folk-Lore* (1884); *The Making of New England* (1886); *The Making of the Great Wes*

(1887); *The Making of the Ohio Valley States* (1894); *The Watch Fires of '76* (1895); *Myths and Fables of To-Day* (1900); *On Plymouth Rock* (1898; 1904); *The Young Vigilantes* (1904).

DRAKE, SAMUEL GARDNER (1798-1875). An eminent American antiquarian. He was born in Pittsfield, N. H., was educated in the common schools, and from 1818 to 1825 taught in a district school. In 1828 he went to Boston, where he established an antiquarian bookstore—the first of its kind in the United States—and devoted himself to the study of early Massachusetts history. He was one of the founders (1847) of the New England Historical and Genealogical Society, was its president in 1858, and for many years was the editor of its quarterly *Register*. He published works on Indian history: *Indian Biography* (1832; 15th ed., under the title *The American Races of North America*, 1880); *Indian Captivities* (1839); besides the *History and Antiquities of Boston* (1856); *Annals of Witchcraft in the United States* (1869); *History of the French and Indian War* (1870). He also edited Church's *Entertaining History of King Philip's War* (1825); Mather's *Indian War of 1675-76* (1862); *Early History of New England* (1864); Hubbard's *Indian Wars* (1865).

DRAKENBORCH, drä'ken-börk, ARNOLD (1684-1748). A Dutch classical scholar. He was born at Utrecht, Netherlands, and, after studying there and at Leyden, succeeded Burmann as professor of history and eloquence at the University of Utrecht (1716). His chief publications are an edition of Silius Italicus (1717), and his masterpiece, an edition of Livy (1738-46), which, though lacking in definite method, contains much valuable material and is still often cited. His *Dissertatio de Præfectis Urbi* (1704) was reprinted with a biography of the author in 1752 (Frankfort).

DRAKENSBERG, drä'kens-bërg. A mountain range of South Africa, running through the eastern part of the Province of the Cape of Good Hope, along the eastern frontier of Orange Free State, and forming part of the northwest frontier of Natal (Map: Orange River Colony, K 6). It forms the eastern rampart of the South African plateau, being steep on the side facing the sea, but with a gradual slope on the inland side. The highest peaks are Mont-aux-Sources, Champagne Castle—both estimated altitudes of 10,500 to 12,000 feet—and Giants' Castle (9600 feet). Its two passes of Van Reenan (5400 feet) and Laing's Nek (4100 feet) are crossed by railways. This region was the scene of numerous battles between the Boers and the British.

DRAKE UNIVERSITY. A nonsectarian, coeducational institution in Des Moines, Iowa. It was founded in 1881, largely through the beneficence of Francis M. Drake, George T. Carpenter, and D. R. Lucas. The management of the university is vested in a board of trustees which will in the course of time number 25 members. The departments represented are those of liberal arts, law, education, Bible, and fine arts; there are also summer schools, and various training schools operated in connection with the university. The degrees conferred by the college and graduate schools include B.A., B.Ph., B.S., B.D., M.A., M.S., LL.B., In 1913 the institution had 80 instructors and 1594 students. The library contains about 26,000

volumes. The presidents of the university and their terms of service have been as follows: George T. Carpenter (1881-93), Barton O. Aylesworth (1893-97), William B. Craig (1897-1902), and Hill M. Bell (1902-).

DRAM. See DRACHMA.

DRAMA (Lat., from Gk. δράμα, from δρᾶν, dran, to act). A form of literary art designed for the direct representation of human actions and characters, through their impersonation by actors before an audience. Though many modern plays have been written in prose, the drama is historically classified as a department of poetry, side by side with the epic and the lyric. The former of these describes events in the narrative form; the latter is the detached expression of individual emotion. Both of these elements may enter into the drama in a subordinate way, but in dramatic poetry the facts of a story are actually developed upon the stage in the interchange of speech and action. It is the action, too, which distinguishes the drama from simple dialogue, in which the persons are mere mouthpieces for the expression of ideas. The drama brings into play every emotion which can be objectively expressed, whether by word or gesture or play of feature, or what the modern playwright describes as "business." The illusion of reality is heightened by the efforts of the scene painter and the stage manager, which, however, belong to the technical side of dramatic art. See THEATRE.

The division of a play into acts and scenes, however (see ACT), is a usage the subject matter of the drama the invention of the drop curtain and scene-shifting accessories make it seem to some extent an affair of mechanical adaptation. The several acts mark different stages in the development of the theme, successively introducing the characters and elements of the plot, showing the complications which led to its climax, and finally solving its problem by the "catastrophe." The natural changes of background commonly coincide with the changes of acts. The succession of scenes (subdivisions of acts) usually depends, in a classical play, upon the entrance or exit of important characters.

The same double consideration underlies the famous doctrine of the "unities," which are in part a formulation of the inevitable restrictions of the stage. They are traced to some of Aristotle's remarks on tragedy, in his *Poetics*, but they were most definitely accepted as conventions of the theatre by the classical French dramatists, Racine and his successors. The "dramatic unities" are three—of place, of time, and of action. The first precludes any extensive change of scene. The second requires that all the events of the play must occur within the space of one day. Unity of action demands that all the incidents of the play shall converge upon the development of a single plot. Of these three rules, modern criticism, with Lessing and the French Romanticists, and according to Shakespeare's practice, is generally agreed in regarding the last as the only one which is fundamental; the others are due primarily to accidental conditions which no longer prevail. Upon the Greek stage, the model for the Classicists, since there was no curtain and very little possibility for change of scene, unity of place was practically inevitable, though even this was not maintained without exception. Unity of time was rendered almost equally necessary

by the habitual presence of the chorus throughout the play, which would be an evident absurdity if the plot were carried across long intervals of time; the same would generally be true if the same chorus were to appear successively in different places. What is called unity of action, however, is simply an application of the principle which demands unity of impression in the work of any art. Only when subordinate to this last "unity" do those of time and place demand consideration upon the modern stage; though it is undoubtedly true that realism of impression is aided if the imagination is not taxed with wide gaps in either time or place.

The question of unity is often practically involved in the creation of a double plot, the secondary or under plot being concerned with the interests of subsidiary characters in the play. This, by way of contrast and relief, may really serve the effectiveness of the main action.

The classic departments of the drama are tragedy and comedy, terms which have come down to us from the Greeks. The essential distinction has been said to lie in the fact that a tragedy has a sad ending, while comedy ends happily; but this is far from expressing all the difference. Tragedy deals in a serious way with serious themes, especially the deeper sufferings of humanity. Comedy exploits the follies and absurdities of the ridiculous and the base. While all drama is intended to entertain, tragedy does it through the excitement of sympathy, comedy through the excitement of mirth. A satirical purpose, however, may dictate the choice of the object of ridicule. The under-plot also, in a tragedy, often introduces a comic element by way of counterpoise to the tragic emotions excited by the principal plot, and of contrast to heighten the impressiveness of the latter; this is one, e.g., of the effects in the grave-digging scene in *Hamlet*. Diversity of plot, however, is much more to be found in modern than in ancient plays. Many species of drama, too, do not fall into the regular categories of either tragedy or comedy. The so-called historical and romantic dramas are sufficiently defined by their names; the *melodrama*, in Italy a form of opera, has become a species of melodrama, and comedy, broadly treated and including the less critical emotions; in France has been defined the sort of play which is named specifically *le drame*, described variously as *tragédie bourgeoise* or *comédie larmoyante*, and representing life with little limitation as to form. (On the musical drama, see OPERA.) Comedy has developed several special varieties, from the "comedy of manners" of the eighteenth century to farce and burlesque and vaudeville (q.v.); the pantomime and ballet (q.v.) are relatively ancient offshoots from the regular drama, if they do not in some cases form part of its origin.

Mimicry, which is fundamental to the acted drama, is of course a part of human nature, and is doubtless to be found among all peoples. In many forms of literature, too, the dramatic tendency appears. Thus, the Old Testament contains dramatic dialogue, as in the Book of Job, and dramatic lyrics, as in the Canticles; they are to be distinguished, however, from developed drama. Regular dramatic history begins in Greece.

Greek Drama, both tragedy and comedy, developed in connection with the worship of Diony-

sus. (See BACCHUS.) In the Dionysiac festivals of Attica the satyr followers of the wine god were impersonated by choruses of men half clad in goatskins—whence probably we have the word tragedy (*τραγῶς*, a goat, and *τραγῳδία*, goat-song)—chanting dithyrambic songs of the life of the god as they danced about the altar. Thus, about 600 B.C. the poet Arion, at Corinth, led his cyclic chorus of 50. A half century later came Thespis, of Attica, whose Thespian innovation was the introduction of an actor to fill the intervals of singing with stories and mimicry and short dialogues with the leader of the chorus. In time the more serious performances came to be limited to the sadder parts of the Dionysus story and of other tales in the familiar mythology. When Pisistratus established at Athens the winter festival of the *Lenææ*, as at the *Great Dionysia* somewhat later, prize dramatic contests were included in honor of the god, and the development of tragedy was continued by Chœrilus, Phrynichus, and other playwrights. It is to the great tragic writers of the fifth century B.C., however, that the Athenian stage owes its fame. Æschylus enlarged the possibilities of the drama by increasing the number of actors to two. Sophocles added a third. The original dithyrambic chorus of 50 men had been divided into four of 12 each (later increased to 15 by Sophocles), with the custom of presenting plays in groups of four, called tetralogies. In one play of each tetralogy the original satyric form was maintained. The other three, the trilogy, properly formed a consecutive series upon a single legend. A tragedy, in general, was made up of a series of "episodes," separated by lyric passages sung by the chorus, the whole introduced by the prologue and terminated by the "exode." During the festival play after play was given the whole day through. The actors were trained by the author himself, so that to "teach" a drama or a chorus became the regular phrase issuing out a play. The expenses of the ; however, were borne by a chosen citizen known as the "choregus," who thus participated in the contest. All dramatic representation was under the control of the state. On the external form of dramatic representation in the great theatre of Dionysus, the masks, costumes, etc., see THEATRE.

The Athenian tragedy was not a mere entertainment, but a serious religious function. Its motive, as defined by Aristotle in his *Poetics*, was to purify the passions of fear and pity through the exalted exercise of them. Characterizations of the "great tragic trio" of Athens have been innumerable, from the time of Aristophanes down. In the dramas of Æschylus the idea of *Nemesis*, divine vengeance, which lies at the heart of Greek tragedy, is an overwhelming mystery. In Sophocles it is visibly a part of the moral law of life, while in Euripides it becomes more simply a source of human sadness. The difference in the attitudes of these three great poets, who were so nearly contemporaneous, is typical of the whole progress of Greek tragedy. Beginning as a popular religious festival, it became a vehicle of expression for some of the deepest solemnities of Greek religious thought and then gradually was secularized and lost its vitality. Ion, Achaüs, Agathon, and other writers who succeeded the great period, are of confessed inferiority, and none of their works have come down to us.

With the dropping of the chorus much of the lyrical element was lost. From being an Athenian institution tragedy spread to other Greek towns, and from the Dionysiac festivals it was extended to others, till its special relation to the worship of Dionysus disappeared. The earlier works were continually reproduced, however, and at Alexandria, under the Ptolemies, tragedy shared in the general revival of literature and the arts.

The development of Greek comedy was parallel with that of tragedy. The name is derived from *κῶμος*, a band of revelers, or from *κῶμη*, a village, with *ὄδῃ*, a song. The rude jests with which the songs of the more rustic Dionysus festivals were enlivened led naturally to a dramatic composition of the same character. Susarion, of Megara, is said to have introduced comedy into Attica early in the sixth century B.C., but before it was encouraged at Athens it came to a considerable development elsewhere, particularly among the Dorians of Sicily, where flourished Epicharmus and Sophron, the inventor of mimes. The history of Athenian comedy is familiarly divided into the three periods of the Old, Middle, and New Comedy. The best-known writers of the first were Cratinus, Crates, Eupolis, and Aristophanes, who is its great exemplar. Organized in a manner similar to tragedy, but with a chorus of 24 and an additional element called the *parabasis*, in which the audience was directly addressed, it dealt frankly in personalities, was largely political, and did not hesitate to caricature the leading men of the day. Middle Comedy marks the beginning of a period when freedom of speech was less unlimited, and when the follies and foibles of whole classes rather than of individuals furnished the butt of the comedian's ridicule. The chorus lost its connection with the drama and was dropped. In the so-called New Comedy of Menander and Philemon, at the beginning of the third century B.C., the tendency seems to have been brought to its logical development. Instead of to political questions of the day, the comic writer devoted himself to the exhibition of ridiculous complications of social life, in a society which with its simplicity had lost much of its virtue. Types were developed which are still familiar upon the stage, such as the gullible old man, the dissipated son, and the tricky and impudent servant, who may be called a sort of male prototype of the soubrette. This later Greek comedy is chiefly known to us through the adaptations of the Roman comedians Plautus and Terence.

By the end of the third century B.C. Greek drama ceased, and was not revived till the middle of the eighteenth and beginning of the nineteenth century. With the stiffening of the national will which preceded the Greek struggle for independence, dialogues of a patriotic nature appeared. This tendency took definite shape in the play of J. R. Nerulos (1778-1850), who was active in the political affairs that led to the revolution, and whose writings did much to pave the way for modern Greek literature. Several other Greek writers joined him in the early nineteenth century in the attempt to rouse the patriotism of the people by means of the theatre. Their work is important only as pioneer work, but its vigor and enthusiasm inspire hope for the future of the drama in Greece.

Roman Drama. Comedy appears to have been the sort of poetry most natural to the

Romans, who had not, on the whole, great dramatic gifts. Comic elements existed in the *saturæ* of the early Latin towns. Yet the Romans borrowed, according to the common account, their first idea of a play, during a period of national despondency (364 B.C., Livy, vii, 2), from the Etruscans, from whom came their word *histrion*, an actor (whence our "histrionic"); the effusions of sportive humor in the rude farces known as *fabulæ Atellanæ* came to them from the Oscans; those called mimes they took from Magna Græcia; their literary drama was almost wholly an imitation of the Greek. The drama was one of the earliest branches of literature to be cultivated at Rome. There were both comedies and tragedies by Livius Andronicus, Nævius, and Ennius, and tragedies by Pacuvius and Attius, besides others less known, all patterned after Greek originals, but practically none of these works have come down to us. Nævius is celebrated for having got into trouble by ridiculing prominent people in imitation, it is said, of the Old Comedy at Athens. Practically all we have of Roman comedy belongs to the works of Plautus and Terence, of the class called *palliata*, closely adhering to their Greek models in scene and subject, in distinction from the so-called *togata*, which had Roman subjects. Plautus was once a poor day laborer; Terence a Carthaginian slave; and the style of each is characteristic. Plautus has a degree of rough vigor and broad jocularity, while Terence is more refined and delicate in his wit and characterization. Both these writers based their work upon the New Comedy of the school of Menander and Philemon. One of the chief forms is to be noted in particular: the *prologus* ceased to be the first act of the play and became the species of detached explanation which it has since remained.

Tragedy, more as literature than for acting upon the stage, continued to be cultivated by many of the writers of the Augustan age and later, with the expressed ambition of rivaling the Greeks. Of all these attempts, however, we have only the 10 rhetorical dramas which are credited to the philosopher Seneca, though they are certainly not all his. One of them, the *Octavia*, is of the class called *prætextæ*, with Roman historical subjects; the others are all from Greek mythology. With the general decline of popular taste under the Empire, all "legitimate" drama fell into decline, and the stage was held by dancers and pantomimes, some of whom became immensely popular favorites. The most celebrated of Roman actors is Roscius, to whose excellence Cicero testifies.

Indian Drama. Another national drama which has been said to be derived from that of the Greeks is that of India; this, however, is a disputed point, and Indian drama is now generally thought to be of independent growth. Like the Greek, it arose in a religious connection, along with the dances and songs of the popular festivals. The Hindu drama, however, has no tragedy and makes far more of the motive of romantic love than does that of the Greeks. Kalidasa, one of the earliest names in its history, as well as the greatest, has been commonly assigned to the first century B.C., but recent criticism places him several centuries later. The best period of Sanskrit drama, then, was from about the fourth to the ninth century A.D. A peculiar feature of the Indian plays, though not without some Greek parallel, is the use of different dialects for different characters.

Gods and heroes and men of high position speak Sanskrit; women and men of low rank speak various forms of Prakrit.

The best-known Sanskrit play is the *Sakuntala* of Kalidasa. It was translated by Sir William Jones in 1789 and is an heroic love drama of great beauty. Kalidasa is also the author of a five-act play called *Vikramorvasi* ('The Hero and the Nymph'). Next in importance among Hindu dramatists was Bhavabhuti, a Brahman of southern India in the eighth century; two of his three plays concern the adventures of Rama, the hero of the epic *Rāmāyana*, on which, indeed, are founded several of the later Indian dramas. Two other noted plays are the *Mricchakatika* ('The Toy Cart'), a drama of social life, in 10 acts, credited to a king named Sudraka, of the sixth century, and *Ratnavali* ('The Pearl Necklace'), a romantic piece supposed to have been written by King Sriharsha, of the seventh century. With the coming of the Mohammedans, the drama in India gradually declined, and, though Sanskrit plays have been written in modern days, they are rarely acted.

Chinese Drama. The only other Oriental branch of the drama that is imparted is the Chinese, which, in spite of the antiquity of other Chinese literature, is comparatively modern. There are reasons for thinking it to have been derived from the Tatars, though it has commonly been considered an evolution from the native songs and dances. In the eighth century A.D. a sort of academy of music, known as the "Pear Garden," was founded by an emperor of the T'ang dynasty. Drama proper did not develop till about the thirteenth century. Its best period is considered that of the Yuen dynasty, ending in the fourteenth century; but perhaps the most famous of all Chinese plays is the one called *Pi Pa Chi* ('Story of the Guitar'), of a somewhat later period. There are many printed collections of plays, but these differ materially from their acted versions. The avowed aims of the Chinese drama are of the most elevated sort, glorifying all the virtues. The pieces themselves are generally rather arid and conventional; as acted, they include much interpolated matter, such as to give reason, perhaps, for the low esteem in which actors are held. Chinese plays are broadly classified, not as tragedies and comedies, but as "civil" or "military." The latter include combats and violent deeds of all sorts. The former are quieter and deal with the more ordinary aspects of social life, with a tendency to the comic. There is little attempt at realism or stage setting. Women's parts are taken by men. Whole series of pieces are commonly performed without intermission—a fact which has led to statements as to the extraordinary length of Chinese plays.

Japanese Drama. The Japanese drama bears somewhat the same relation to the Chinese as the Roman did to the Greek; it is largely an importation, though in the process of adaptation it has struck roots into the soil and taken on a semblance at least of independent life. But conditions in Japan are not such as to foster a vigorous dramatic growth. The drama is wholly divorced from literature and consequently occupies a very low position in the esteem of the better classes. Until recently both actor and dramatist were held in contempt. This situation has been somewhat relieved, however, by the dramatic reform association, and scholars, the purpose

of which is to elevate the drama to the position it occupies in other civilized countries.

Aboriginal American Drama. The only drama of importance developed among the native civilizations of America was the so-called Inca drama of Peru, of which only a single fragment has been preserved.

Mediæval Drama. Europe during the Middle Ages saw dramatic progress in one direction. Many of the Christian Fathers condemned dramatic exhibitions of all kinds, but the Church as a whole, more practical, undertook to offset the pagan shows by a Christianized equivalent. This seems to have arisen naturally, out of the responsive chants and narrations of biblical events with which the congregations were both instructed and entertained, and which in time came to be a regular liturgical drama, developing into the *miracle plays* (q.v.), and *mysteries* (q.v.), and *passion plays* (q.v.), which at Oberammergau and elsewhere have come down to our own day. With a similar purpose arose also the *moralities* (q.v.), which were often rendered by wandering churchmen. Out of such beginnings, varied somewhat by occasional secular tendencies (see *FARCE*), modern drama may be said to have promised to develop, when the Renaissance came with a new impulse.

Italian Drama. In Italy, where the revival of the classical type was earliest, the religious drama reached a considerable degree of literary progress before it was superseded. The fifteenth century saw the development of the so-called *Rappresentazione Sacra*, produced chiefly in connection with the festivities in honor of St. John the Baptist. Notable among these are the *Abramo e Isacco* (1449) of Feo Belcari and Lorenzo de' Medici's *San Giovanni* and *San Paolo*.

The modern history of the drama in Italy, passing by less regular attempts like that of Poliziano, is considered to begin with Trissino's *Sofonisba* (1515), a dull and conventional tragedy in blank verse. About the same time Plautine comedy was revived in the writings of Cardinal Bibbiena, Ariosto, and Machiavelli. Tasso's *Aminta* (1573) set a fashion of pastoral drama which was much imitated. Towards the end of the century Giambattista della Porta, playwright as well as philosopher, exhibited a number of comedies of a familiar and sometimes even farcical kind, but of an agreeable originality. The political influence of Spain was now at its height on Italian territory, and the romantic drama of the West gradually found favor in Italy. Borghini, Michelangelo Buonarroti, nephew of the great artist, and other writers continued the reaction against the domination of the classic taste; notable in the movement were Buonarroti's comedies, *Tancia* (1612) and *Piera* (1618). About the beginning of the seventeenth century, too, Rinuccini and others, by the union of music with the romantic drama, succeeded in establishing what was called *melo-drama*. Regular tragedy and comedy were well-nigh superseded, and all Italy turned to the *musica opera*. Zeno, a century later, fixed the musical drama on a literary level, and in it Metastasio, whose popularity was established by the performance in Rome (1723) of his *Didone Abbandonata*, completely fascinated the Italian public. His long series of works culminated in the triumph of his *Atilio Regolo* (1750).

Meanwhile, however, the regular drama had been revived. The archaeologist Maffei composed his *Merope* (1713), with the definite purpose

of restoring the classic tragedy to Italy. The political preponderance of Spain had now given way to that of France, and Maffei's friend, the actor playwright Riccoboni, contributed not a little to the consequent increase of French influence upon the Italian stage. The other foremost names of the eighteenth century in Italian drama are those of Goldoni (1707-93), Gozzi (1722-1806), and Alfieri (1749-1803). Goldoni, who left his native Venice in 1761 to complete his life in Paris, has been called "the Italian Molière"; he is the great Italian exemplar of regular literary comedy. His great rival, Carlo Gozzi, won fame in quite a different style. Taking the popular institution of the *commedia dell' arte* ('comedy of masks'), for which Goldoni expressed contempt, he gave it a literary form which for a few years enjoyed immense success. The bold and passionate Alfieri inaugurated a new era in Italian tragedy. He was a follower of the classic school, an observer of the unities, and aimed, while writing such tragedies as *Filippo II*, *Saul*, and *La Congiura de' Pazzi*, to help revive the vigor of the national spirit. His successors, among them Monti, Niccolini, Manzoni, Silvio Pellico, and, later, Cossa, somewhat relaxed their adherence to classic forms; in the nineteenth century Italy shared in the extending influence of Shakespearean methods. The dramatists thus affected have given prominence to historical drama, and some of their works have been of a high order. In recent years the novelist and poet D'Annunzio has gained some distinction as a playwright, with poetic dramas written for the actress Duse. It would scarcely be an exaggeration to say that for the past century the influence of the Italian actors has been greater than that of the dramatists. Since the renovation of the stage through the efforts of G. Modena (1804-61) Italy, with the possible exception of France, took first rank in the art of acting; and in the art of tragic acting she surpassed even France. In the past century Ristori, Rossi, Salvini, and Duse have all won international reputations.

Spanish Drama. The great period of the Spanish drama came earlier than did that of Italy and at a time when the best poets, while writing for the stage, still busied their pens in the composition of religious dramas in the service of the church. Passing over some of the earlier names—among them those of Santillana, Lope de Rueda, who, as actor, manager, and playwright, has been called the "Patriarch of the Spanish stage," and his follower Naharro—we come to the century of Cervantes, Lope de Vega, and Calderón. The genius of Cervantes was more decidedly epic than dramatic. Yet in *La Numancia* he has left a serious tragedy of permanent worth and dignity. Contemporary with him were the lesser writers Cueva, Virués, and Argensola. While the critics, however, were clamoring about the classic rules of the drama, Lope de Vega appeared upon the scene, to set nearly all the laws at defiance. He was a writer of the most prodigious facility as well as dramatic vigor. More than 1800 plays are said to have been his work, and he won immense popularity, to which, indeed, he sacrificed some of the more enduring qualities. Of the same period were Ruiz de Alarcón and Tirso de Molina (Gabriel Tellez), whose *Burlador de Sevilla, ó el convidado de piedra* is a play notable for having introduced the famous character of Don Juan. Calderón, who succeeded to the greatness of

Lope de Vega, had the additional merit of serious devotion to dramatic art. The lyric element is prominent in his plays, and they include many of the highest expressions of Spanish ideals, of devotion to the King, to the church, and to personal "honor." Famous among his creations were the religious plays called *autos sacramentales*, in which the mystery of the Eucharist was dramatically set forth. With his death, in 1681, the brilliant period of the Spanish theatre was nearly closed. His contemporary Moreto wrote numerous fine comedies, notably the "cloak and sword plays," for which the Spanish stage is proverbial; and the name of the historian Solís is worthy of mention. But with the decline of the national spirit, which began about the close of the seventeenth century, the art of drama fell into decay; and during almost the whole of the eighteenth century the Spanish theatre was under the domination of French influence. The dramatists of the nineteenth century succeeded in emancipating themselves from this influence so far as form was concerned, but continued to imitate the French romantic school in their choice of subjects. They produced, therefore, little that was original or that reflected the national life. The best-known dramatists of the twentieth century are J. Echegaray and Menendez Sierra.

Portuguese Drama. With minor exceptions Portuguese drama follows Spanish in the course of its development. The most renowned writer of the early period was Gil Vicente, who wrote in imitation of De la Engima, the founder of Spanish drama. His plays were produced in the years 1502-36 and achieved wide popularity. Following him, F. de Sá de Miranda attempted to introduce a type of play imitated from the Italian comedy of intrigue, but failed of popular success, though his plays possessed greater literary merit than those of Gil Vicente. In the eighteenth century Alino Mycenio and Lycidas Cynthio are the only names of importance. The notable nineteenth-century dramatists are Pereira de Cunha, Cordeiro, Biester, Palmeirín, and De Amorim.

French Drama. France, in the revival of the classical drama, accepted the "unities" as the first essentials in the drama. This was in great part owing to the logical temper of the national genius. Previous to Jodelle, or, indeed, to Corneille, hardly any drama had been made in regular dramatic form. A number of writers had produced *mystères*, *moralités*, *sotties*, *farces*, in which in numerous instances the romantic or anticlassical tendencies of human nature had manifested themselves; but neither in the representations of the *Confrères de la passion* nor more secular performances like those of the *Enfants sans Soucy* was there any great advance in proper dramatic achievement. Jodelle, at the court of Henri II, was the first to exhibit a regular five-act tragedy. He composed other pieces of some merit, but nothing of any great importance to the drama was done in the half century that succeeded. Corneille appeared in the reign of Louis XIII during the time that the star of Richelieu was in the ascendant; he had to humor the court by humoring the Academy, and to please the Academy he was required to observe the rules of Aristotle. He had produced several plays of a severe elegance and dignity of style, when inspiration came to his more romantic tendencies in the Spanish story of the *Cid*. All Paris rang with the praises of

this play; but the French Academy, acting on the suggestion of Richelieu, took occasion to censure it on the ground that it violated the classical "unities." Corneille, who was ambitious of election to the Academy, carefully avoided giving similar offense afterward. The final establishment of the rule of the three "unities" was largely due to his acquiescence, though it is obvious from his work that he never felt quite at home within the limitations he had imposed on himself. He obtained, however, the position in the Academy which he coveted. It was in Molière, a contemporary of Corneille, that French drama found its highest expression. This was partly due to Molière's own genius and partly to the fact that the spirit of the French people may be better rendered in comedy than in tragedy. Unlike Corneille, Molière sought to portray the life about him, especially such phases of it as lent themselves to humor or satire. He had led a varied life, living in Paris, where his father held a subordinate post in the King's household (to which Molière nominally succeeded) and traveling in the provinces as a strolling actor, so that he had ample opportunity to observe at first hand the wide variety of characters with whom he later peopled his plays. Before his time French comedy had been content merely to provoke laughter; he lifted it from this position and made of it a rich and varied commentary on life. The favorite tragic poet of the court of Louis XIV was Racine. His powers lay decidedly in the region of the serious and the exalted, so that he had no temptation, like Corneille, to pass the bounds of the academic proprieties. In tenderness and elegance all French writers yield to him; in his *Athalie*, his last and best drama, interpreted by the actors Baron and Madame Champmeslé, he gave to the Parisian public a composition such as in breadth, elegance, and severe grandeur it could nowhere find apart from the Greek theatre. Passing by Boursault and the other lesser writers who saw the decline of Racine and Molière, and such artists on the stage as Adrienne Lecouvreur, Lekain, and Mademoiselle Clairon, we come to the brilliant and erratic Voltaire. He astonished Europe with the force and power of his romantic tragedies, in a style of composition which, since the *Cid*, had been excluded from the theatre. The intolerant iconoclasm of his warfare with superstition was perhaps too distinctly revealed in his dramas, but his genius and spirit have earned for him a place beside the great tragic names of Corneille and Racine. Among the writers of the period that followed were Lemercier and Chénier, whose tragedy of *Charles IX*, played by Talma, led to the division of the Comédie Française, while among the other famous actors at the national theatre were Mademoiselle Dumesnil, Monvel, and his daughter, Mademoiselle Mars.

In the nineteenth century the drama of France has been more productive than that of any other nation. Notable among the writers of the century are Alfred de Vigny, Scribe, and Legouvé, who collaborated in a large number of successful pieces, Dumas père, and Victor Hugo—leaders of the "romantic movement," the battle over which converged about Hugo's *Hernani* in 1830—Alfred de Musset, Emile Augier, Dumas fils, Victorien Sardou, Octave Feuillet, Eugène Labiche, Meilhac and Halévy, Emile Zola, and more recently Edmond Rostand, who has very successfully revived the poetical play. No sketch of the

French drama can overlook the services of an institution like the Comédie Française (q.v.) in maintaining the literary qualities of the stage and encouraging its support by the leading writers of the nation, while artists like Mademoiselle Rachel, Sarah Bernhardt, and Constant Coquelin have often been better known than the authors whose lines they spoke. It is too early to speak with assurance of the drama of the twentieth century, but if early indications are to be trusted France promises to maintain her position of preëminence. A host of new writers have come forward and are already well known throughout Europe and America. Chief among these are Maurice Maeterlinck, Paul Hervieu, Maurice Donnay, Jules Lemaitre, and Eugène Brieux. Their work differs widely, but they all, with the exception of Maeterlinck, show the influence of the naturalist movement which began with the founding of the Théâtre Libre in 1887.

German Drama. The German drama is almost wholly dependent for its fame upon the names of Lessing, Goethe, and Schiller. For while Hans Sachs, Ayser, and some others showed ability and some fertility, and while Gryphius, Gottsched, Gellert, and Schlegel made advances in the appreciation of the laws of dramatic composition, yet through the end of the seventeenth and the beginning of the eighteenth centuries the German theatre was little more than a feeble reflex of French influence. Lessing, however, taught Germany to appreciate the productions of the romantic drama, both by his creations and by his criticisms. His *Miss Sara Sampson*, his comedy *Minna von Barnhelm*, and his later tragedies opened a new era for the German drama, while in his *Hamburgische Dramaturgie* he attacked French classicism, praised Shakespeare, and professed his adherence to the principles of Aristotle. Goethe, his great successor, is without doubt one of the world's foremost geniuses; but he was poet and philosopher rather than dramatist. His *Faust* must always retain its place as one of the greatest of modern compositions; but his chief purpose was complete self-cultivation, and in the prologue to this, his last and by far his most famous production, he sets forth why, although writing in the dramatic form, he could not altogether accommodate himself to the demands of a popular theatre. Schiller was more expressly the dramatic poet of Germany than Goethe. While Goethe's genius was fuller and more complete, Schiller made up for what he wanted in breadth of vision by the practical intensity of his powers. From his wild play of *Die Räuber* down to his last drama of *Wilhelm Tell*, he worked with a vehemence that made an enduring impression upon the national theatre. The demands for a more popular drama were supplied by such writers as A. W. Iffland and August von Kotzebue, both of whom sought to supply effective plays for the stage and were indifferent to the demands of art. In the early nineteenth century a group of Romanticists, under the leadership of the Schlegels, sprang into prominence, but their vogue was short-lived. The most successful dramatist of this period was the Austrian Franz Grillparzer, whose best work was done from 1819 to 1830. The German drama of the last quarter of the nineteenth century and the beginning of the twentieth, like most modern drama, is characterized by extreme naturalism, though some of it is written in verse. The leading contemporary dramatists are Hermann Sudermann and Gerhart Hauptmann.

Dutch, Scandinavian, and Belgian Drama. Among the Dutch the drama has had but slight independent growth. In the sixteenth and seventeenth centuries Van den Vondel and others participated in the dramatic revival that followed the Renaissance; but the later Dutch stage largely imitated that of France. The first important dramatist of the Scandinavian countries was the eighteenth-century Danish poet Holberg. He was one of the first comic poets of his day, and his plays did much to supplant the trivial German and French importations common on the Danish stage. Like Molière, he chose his characters and subject matter from the life about him and ridiculed with unsparing directness the vices and follies of his time. Following him, Oehlenschläger, in the first half of the nineteenth century, inaugurated a new era in Danish drama by the production of a series of plays dealing with subjects from Norse mythology. But by far the most significant development in Scandinavian drama—in all contemporary drama, perhaps—came towards the end of the nineteenth century. Its chief promoters were the two Norwegians, Ibsen and Björnson, and the Swede Strindberg. Of the three Ibsen's influence has been much the greatest. It is to him largely that we owe the modern social drama. He did not originate the type, but his example and influence gave it currency and helped to fix it in popular favor. Strindberg, who was a much more prolific and in some respects a more powerful writer, is little known outside his own country; but his work seems to be gaining in favor in spite of its morbid tone and generally melancholy aspect. In Belgium, which has been counted, from an artistic point of view, as a province of France, the most noted work of recent years has been that of the poet Maeterlinck, whose plays have served as an extreme type of some of the features of the Symbolist movement.

Russian Drama. Russia has been somewhat slower in developing a national drama than the other European countries. Dramatic representations of a sort began at an early period, but regular plays were not performed before the middle of the eighteenth century. Sumarokov, who was born in 1718 and died in 1777, was the first regular dramatist. He wrote tragedies in imitation of Racine and Voltaire and translated *Hamlet* into Russian. He also wrote comedy, in which he had several noteworthy followers. The Empress Catharine II herself tried her hand at satirical comedy and also wrote a tragedy in imitation of Shakespeare. To the nineteenth century belong Griboyedoff, the author of *Gore ot Uama* ("The Misfortune of Being too Clever"); Gogol, whose comedy *Revizor* ("The Inspector") made a great sensation; Pushkin, whose *Boris Godunoff* shows the change from French to Shakespearean influence; and Tolstoy, who wrote plays, though he is better known as novelist and philosopher; and Ostrovski, a writer of numerous comedies.

English Drama. In England, as elsewhere, the early dramatic exhibitions were connected with the church. Ecclesiastics were at first not only the authors but the actors of the miracle-plays and mysteries by which religious instruction was combined with a good deal of grotesque amusement. The moralities, in which abstract qualities were personified, marked an imaginative advance, and the early comedy was to some extent an evolution from them, through the gradual substitution of real and strongly char-

acterized persons for mere abstractions. But the main influence towards comedy came from the imitation of classic models. *Ralph Roister Doister*, usually considered the earliest English comedy, was little more than an imitation of the *Miles Gloriosus* of Plautus. The same thing may be said of most of the early comedies. They were either adaptations from, or direct imitations of, classical and Italian plays. A few years after *Ralph Roister Doister* appeared the first tragedy, called *Gorboduc*, or *Ferrex and Porrex*, a dull and declamatory production in blank verse by Sackville and Norton. From this time dramatic production was rapid, though at first without great improvement. To pass by the names of Bishop Still and of Kyd, Lodge, Lyly, Peele, Green, and Nash, mention is due to Christopher Marlowe as the greatest of Shakespeare's predecessors. He is the author who first introduced upon the public stage blank verse, the vehicle of English drama, and there are passages in his tragedies of *Doctor Faustus* and *Edward II* which are accounted not unworthy of Shakespeare himself.

But all these earlier playwrights are obscured by their nearness to the great luminary of the English drama. Shakespeare is almost universally acknowledged to have been the greatest dramatic genius that has appeared in the world. Disregarding or ignorant of the "unities" and the artificialities of a stage as yet unaided by any but the most primitive scenic accessories, he brought the romantic drama to its highest perfection. His writings present the finest example of the depth, sublimity, refinement, and variety of which the drama is capable; and they are abundantly marked by those peculiar characteristics which sprang from the union in their author of such wonderful powers of conception with such familiar experience of theatrical management. (For a more detailed discussion of his plays, see the special article SHAKESPEARE.) Of the other actors of Shakespeare's time we know less; but Burbage and Alleyn are among those whose names have come down to us. Among dramatists the best of Shakespeare's contemporaries were Ben Jonson, Beaumont, and Fletcher. Like Shakespeare, Jonson wrote both comedies and tragedies, but he showed more of the influence of the classic models. Milton speaks of "Jonson's learned sock" and thus in a phrase hits off the main feature of his character as a dramatist. Yet he was famous in the composition of such light and graceful pieces as the masques in which the court found entertainment. (See MASQUE.) Beaumont and Fletcher, who were joint workers, have the honor of standing next to Shakespeare in the romantic drama of England; but, like Lope de Vega, they wrote too much for the success of the moment to be ranked in the foremost file of England's dramatic writers. With Dekker, Massinger, Ford, Webster, Chapman, and Shirley, the older English drama is closed, sharply terminated by the Puritan Revolution.

With the Restoration came a dramatic representation much more the reflection of the court and in its form largely reflecting French influence. Under the direction of such managers as Davenant and Killigrew plays were much more elaborately staged than before, and the drama was very much better patronized. On the stage were Betterton and Mrs. Barry. The chief literary figure of the time was Dryden, who wrote successfully both tragedy and comedy. The trag-

edies of Lee and the unfortunate Otway, with such comedies as those of Shadwell and Wycherley, bring the history of the drama down to Vanbrugh, Congreve, and Farquhar, writers whose brilliant depiction of the externals of society is clouded by an immorality and an indecency even more marked than that of some of Shakespeare's immediate successors. Gay and Mrs. Centlivre, and the actor playwright Colley Cibber, displayed in their comedies considerable dramatic spirit and invention. Of quite another sort was Addison's tragedy of *Cato*, famous in the annals of literature and successful on the stage for the old-fashioned political virtues which it solemnly set forth. Lillo, Moore, Garrick the actor, Goldsmith, the Colmans, and Cumberland nearly all took to prose instead of verse. They produced agreeable comedies; but, except Goldsmith's *She Stoops to Conquer* and one or two other pieces, nothing very important appears in the history of the drama till the time of Sheridan, who gave an impulse to "high" comedy such as has placed him ever since at the head of the writers of that species of composition. Famous among the favorites of the stage meanwhile had been "Peg" Woffington and Katharine Clive.

Sheridan's immediate successors—Holcroft, "Monk" Lewis, Maturin, Mrs. Inchbald, and others—have left little that is remembered; but such interpreters of the drama as John Kemble, Mrs. Siddons, and later Edmund Kean, save the period from unimportance in dramatic history. Joanna Baillie, the poets Byron and Coleridge, and Henry Taylor, wrote fine meditative dramas, little suited, however, for actual presentation upon the stage; and the same may be said of much of the more recent dramatic poetry of Tennyson, Browning, and Swinburne. The list of writers for the English theatre in the nineteenth century is long. Among the earlier ones Sheridan Knowles and Bulwer-Lytton wrote plays which are still known on the boards. Later came Talfourd, Jerrold, Shirley Brooks, Tom Taylor—who wrote over 100 pieces, many of them very popular—Marston, Wills, Charles Reade—who, with Boucicault or alone, dramatized several of his own works—T. W. Robertson, H. J. Byron, Sydney Grundy, Oscar Wilde, W. S. Gilbert—who is best known, however, for the comic operas in which he collaborated with Arthur Sullivan—H. A. Jones, A. W. Pinero, Hadson Chambers, J. M. Barrie, H. V. Esmond, and Stephen Phillips. Not to be neglected also in our account is the important influence of such actor managers as Macready, Buckstone, the Bancrofts, Sir Henry Irving (to whose company belongs Ellen Terry), and Sir Charles Wyndham, in giving direction to dramatic production. Of the more recent dramatists who have come into prominence Shaw, Galsworthy, Granville Barker, and Somerset Maugham are the most noteworthy. Shaw in particular, since the beginning of the century, has risen, to a position of international importance.

American Drama. The American stage was naturally in its origin a mere dependent upon that of England; and the sameness of language, the similarity of dramatic themes, and the constant interchange of English and American actors still make it difficult to separate the drama of the United States from that of Great Britain. At the present day American successes are reproduced in England hardly less than successful English plays on this side. In-

dependent dramatic production in America, however, as an infant industry labored under one particular disadvantage, owing to the absence till 1891 of an international copyright. A manager could always adapt, translate, or reproduce outright, at no expense and little risk, a play that had met success abroad; whereas to purchase one from a native writer involved at the outset a definite outlay and the subsequent risk of failure. Partly in consequence of this, dramatic history in America has had to do more with players than with playwrights. Yet the literature of the drama in the United States is extensive, though, as in England, much of it is of little value. Not a little of that belonging to the years which followed the Revolutionary War consisted of trashy pieces for the exploitation of crude patriotism; and forth the yet unseasoned glories of the achievements. It had been only a few years before the Revolution that the first permanent playhouse was built—the Southwark Theatre in Philadelphia (1766)—followed the next year by the opening of the John Street Theatre in New York. Here in 1787 was presented what is considered the first play by an American author regularly produced upon the stage—*The Contrast*, written by Royall Tyler, afterward Chief Justice of Vermont. It has been asserted, however, that Godfrey's *Prince of Parthia* was acted in Philadelphia some 20 years before. The dramatic qualities of *The Contrast* were of the slightest, but it served to introduce to the boards the personage known as the exaggerated "Yankee," who could not be banished for three-quarters of a century. The first prolific American dramatist was William Dunlap, some of whose work was fair for the period. He produced about 50 plays, a few of them translated from the German. The opening of the Park Theatre, New York (1798), gave a new impulse to the drama, although the chief players were from the old country and the opening play was *As You Like It*. Here, in 1809, "the American Roscius" made his début as Young Norval. This lad was John Howard Payne. He not only appeared with great success in this country and in England, but he wrote and translated a number of plays, of which his own *Brutus*, or *the Fall of Tarquin*, still keeps the stage. It is a well-constructed tragedy and is the first drama of importance written by an American author.

It was not until about 1820 that literary and cultured people began to look with favor upon the drama. In that year the great tragedian Edmund Kean visited America and played in New York and Philadelphia. Ten years later came his son Charles. The great and erratic Junius Brutus Booth first appeared in the United States in 1821; he came again in 1833. Macready made his first visit in 1826. Clara Fisher came in 1827. The season of 1832–33 brought over Charles and Fanny Kemble, who enjoyed an immense popularity. Meanwhile the elder Kean was hardly gone after his second visit when Edwin Forrest appeared in New York in the Shakespearean part of *Othello* (1826). Forrest is held in memory by many as the greatest of American tragedians. While doubtless at his best in Shakespearean tragedy, he was always intensely American in feeling and undertook to infuse the native idea into his work. John A. Stone's *Metamora* was written for him, as was also R. N. Bird's tragedy of *The Gladiator*. One of the most popular of For-

rest's contemporaries was the comedian James H. Hackett, who became famous as Falstaff and in "Yankee" rôles. John Gilbert made his début in Boston in 1828, and later ripened into one of the most accomplished actors of "old man" parts on any stage. William E. Burton came to the United States in 1834. Charles Burke, one of the finest of American comedians, began his short career in 1836. He was a half brother of Joseph Jefferson, who about the same time made his appearance as a boy upon the stage and subsequently more than realized the promise of his theatrical ancestry. Already Charlotte Cushman, celebrated as the greatest of American actresses, had begun to show her power. In 1838 Mary Cecilia Taylor made her début and soon became a popular favorite, a clever and versatile though not a great actress. Still the stage was largely dependent on English materials when John Brougham came over in 1842. He was the first author to put life into the playbills, besides being one of the best comedians of the day, and, though he was born an Irishman, his work was essentially American, especially his inimitable burlesques, *Pocahontas* and *Columbus*. In 1845 the elder John Drew appeared in America. Meanwhile Anna Cora Mowatt was becoming the reigning favorite in genteel comedy and light tragedy, and in 1848 she appeared in England with E. L. Davenport, who had already at home made a reputation as a versatile actor.

During the second half of the century just passed the annals of the American stage offer a long list of names worthy of respect as those of gifted and admirably trained artists. In tragedy it is necessary only to recall Edwin Forrest, who still played till after 1870; John McCullough, best remembered for his manly impersonation of Virginius; Edwin Booth and Lawrence Barrett, two of the most scholarly of American actors; and Richard Mansfield, who was not only a tragedian, but a successful actor in other branches of the regular drama. In legitimate comedy John Gilbert and Joseph Jefferson led the way, and were followed by Lester Wallack, E. A. Sothorn, William Davidge, William J. Florence, James Lewis, John T. Raymond, Sol Smith Russell, John Drew, and N. C. Goodwin. In lighter comedy and farce some of the names suggesting themselves are those of William H. Crane, Neil Burgess, Henry E. Dixey, and Francis Wilson. Of the talented and accomplished women who have graced the stage, Charlotte Cushman was still the foremost a half century ago. Among the others most noted have been Mrs. Anne Gilbert, who at her eightieth birthday (in 1901) was still playing; Elizabeth Crocker Bowers, Maggie Mitchell, Matilda Heron, Laura Keane, "Lotta" Crabtree, Rose Coghlan, Clara Morris, Fanny Davenport, Mary Anderson, Ada Rehan, Minnie Maddern Fiske, Annie Russell, Julia Marlowe, Mrs. Leslie Carter, and Maude Adams. A continually increasing number of well-known foreign actors and actresses have made American tours; some of them, like Madame Janauschek and the late Dion Boucicault, the playwright, made America their home.

The list of American dramatists not already referred to includes Harrigan and Hart, Augustin Daly, Lester Wallack, Bronson Howard, James A. Herne, H. C. De Mille, Denman Thompson, David Belasco, Clyde Fitch, Augustus

Thomas, William Gillette, William Vaughan Moody, Charles Klein, Eugene Walter, Percy Mackaye, George M. Cohan, and Edward M. Sheldon.

For a fuller treatment of matters relating to the drama, the reader is referred to the articles that deal with the individual actors and authors mentioned above, and to those entitled THEATRE; BALLET; BURLESQUE; CHORUS; CLAUQUE; COMÉDIE FRANÇAISE; FARCE; INTERLUDE; MASQUE; MIRACLE PLAYS; MYSTERY; PANTOMIME; ETC.

Plays and Playwrights (Boston, 1913); Doran, *Annals of the Stage* (Lowe ed., London, 1888); Scott, *The Drama of Yesterday and To-Day* (ib., 1899); Matthews and Hutton, *Actors and Actresses of Great Britain and the United States* (New York, 1886); Dibdin, *A Complete History of the English Stage* (London, 1800); Jussérand, *Le théâtre en Angleterre* (Paris, 1881); Fleay, *A Chronicle History of the London Stage, 1559-1642* (London, 1890); Hazlitt, *The English Drama and Stage under the Tudor and Stuart Princes, 1543-1664* (ib., 1869); Schelling, *Elizabethan Drama* (Boston, 1908); Clarke, *The Miracle Play in England* (London, 1897); Chambers, *The Medieval Stage* (ib., 1902); Thorndike, *Tragedy* (ib., 1908); Filon, *Le théâtre anglais: hier, aujourd'hui, demain* (Paris, 1896); Winter, *Other Days: Chronicles and Memoirs of the Stage* (New York, 1908) and *The Wallet of Time* (ib., 1913); Moses, *The American Dramatist* (Boston, 1911); Hunt, *The Play of To-Day* (New York, 1913).

DRAMA LEAGUE OF AMERICA. An organization started in Evanston, Ill., in 1910. It spread rapidly and now embraces practically all the principal cities of the United States. The purpose of the league is to encourage good plays by pledging the support of the members during the first 10 days after production and by . . . and educating an intelligent play-going audience that will be nation-wide, thus insuring the success of all worthy plays and creating a higher standard of dramatic art. Realizing that the success or failure of most plays is determined the first few days after production, the playgoing committee of the league visits all plays produced and sends out a bulletin of information concerning those deemed worthy of support. This bulletin is mailed to all members of the league in the city or "dramatic centre" where the play is being given, and contains brief but definite information concerning the theme, plot, dialogue, characters, and other details of the production. Plays deemed unworthy of support are not condemned, but ignored. Recently an attempt has been made to extend the movement to Canada and Great Britain.

DRAMATIC ARTS, AMERICAN ACADEMY OF. . . . l for the stage, established by . . . in New York City in 1884 and chartered by the regents of the State of New York in 1889. It offers a two years' course of systematic instruction. In 1897 the Empire Theatre Dramatic School was placed under the management of the Academy. The senior class offers several public performances.

DRAMATIC MUSIC. See OPERA.

DRAMATIC POESY, AN ESSAY ON. A treatise (1667) by Dryden in the form of a dialogue.

DRAMMEN, dräm'men. A seaport town of Norway, situated on the Drammen Fjord, at its entrance into the Drammen Fjord, an arm of the Christiania Fjord, 33 miles southwest of Christiania (Map: Norway, D 7). The town occupies a site between high hills and has been rebuilt since the fires in 1866, 1870, and 1880. The three quarters of the town, which are divided by the river, are joined by bridges. Drammen manufactures chiefly lumber; also ironwork, tobacco, cellulose, paper, cotton, and woolen textiles. It has saw mills and shipyards and exports much lumber, zinc, nickel, and cobalt. Its trade is largely with England and Holland.

Near by are large salmon fisheries. Pop., 1902, 23,091.

DRAPER, ANDREW SLOAN (1848-1913). An American educator; also a lawyer. He was born at Westford, N. Y., graduated in 1871 from the Albany Law School, and until 1885 practiced in Albany, except for a year when he served in the State Assembly. In 1885-86 he was a member of the Court of Commissioners of Alabama Claims, afterward until 1892 he was New York State Superintendent of Public Instruction, in 1892-94 he had charge of Cleveland (Ohio) schools, and for 10 years he was president of the University of Illinois. Appointed in 1904 first State Commissioner of Education for New York, he served in this position until his death. For some time he was also chairman of the Board of United States Indian Commissioners. At the Paris Exposition of 1900 he was awarded a silver medal for a monograph on *The Organization and Administration of the American School System*, and at St. Louis in 1904 he received one of the two grand prizes for unusual services to the cause of education. His publications include: *American Schools and American Citizenship* (1891); *Public School Pioneering in New York and Massachusetts* (1892); *Conserving Childhood* (1909); *Holiday Papers* (1912). He was also editor in chief of *Self-Culture for Young People* (10 vols., 1906).

DRAPER, DANIEL (1841-). An American born in New York City, a son of John William Draper, under whom he studied science. He obtained his degree from the University of the City of New York. He helped his brother, Henry Draper, to construct the telescopes, grind the mirrors, and build his observatory at Hastings-on-the-Hudson. From 1869 to 1911 he served as director of the New York Meteorological Observatory. The self-recording meteorological instruments employed in that institution are based chiefly upon his designs. Among his literary contributions to science may be mentioned the well-known treatise on the *Cause of Pneumonia*, which has also been translated and reprinted abroad.

DRAPER, EBEN SUMNER (1858-1914). An American Republican leader and manufacturer of textile machinery. He was born at Hopedale, Mass., and was educated at Massachusetts Institute of Technology. He became a member of the firm of George Draper & Sons in 1880 and selling agent of the Draper Company in 1896, was chosen a director of various banks and cotton-manufacturing corporations, and became president of the Manville Company and vice president of the Massachusetts Hospital Life Insurance Company. He was chairman of the Republican State Committee (1892) and of the Republican delegation to the Republican National Convention (1896) and was presidential elector (1900). From 1906 to 1908 he was Lieutenant Governor, and from 1909 to 1911 Governor, of Massachusetts.

DRAPER, HENRY (1837-82). An American scientist, the son of John William Draper. He was born in Prince Edward Co., Va., studied in New York from 1852 to 1854, and began the practice of medicine in 1858. He was then professor of physiology in New York University from 1860 to 1866, professor in the medical school from 1866 to 1873, and afterward professor of chemistry. He constructed large telescopes and devoted himself to celestial photography, rendering important service to astronomy

and astrophysics. The continuation of his spectroscopic investigation of the stars, which was cut short by his death, was provided for by the endowment of the Draper Memorial at Harvard College Observatory by his widow in 1886. He published *On the Construction of the Silvered Glass Telescope* (1864; 1904) and *A Text-Book on Chemistry* (1866).

DRAPER, JOHN CHRISTOPHER (1835-85). An American physician, born in Virginia. He was a son of John William Draper. He entered the academic department of New York University in 1852, but subsequently abandoned the study of the classics, attended the course in medicine, and graduated in 1857. He was professor of analytical chemistry, New York University (1858-61), of chemistry at Cooper Union, New York City (1860-63), of natural science at the College of the City of New York (1863-85), and of chemistry in the medical department of New York University (1866-85). He contributed numerous articles to medical and scientific journals, was editor, in 1872-73, of the *Year-Book of Nature and Science*, and for three years had charge of the department of natural science in *Scribner's Monthly*. His important works include: *The Production of Urea* (1856); *Experiments on Respiration* (1856); *Text-Book on Anatomy, Physiology, and Hygiene* (1866); *A Practical Laboratory Course in Medical Chemistry* (1882); *Text-Book of Medical Physics* (1885).

DRAPER, JOHN WILLIAM (1811-82). An American chemist, physiologist, and philosophical writer. He was born near Liverpool, England, and was educated at a Wesleyan school at Woodhouse Grove and at London University. In 1831 he joined some of his relatives who had emigrated to America, and in 1836 took his degree of M.D. in the University of Pennsylvania and was appointed professor of natural philosophy, chemistry, and physiology in Hampden-Sidney College, Virginia. In 1839 he removed to New York, where he was connected with the college department of the University of the City of New York; and in 1841 joined Drs. Mott, Patterson, and others in founding the medical school of New York University, in which he was at first professor of chemistry and after 1850 of physiology. He was the first president (1876) of the American Chemical Society. He published: *Treatise on the Forces which Produce Organization in Plants* (1844); *Text-Book of Chemistry* (1846); *Text-Book of Natural Philosophy* (1847); *Human Physiology, Statical and Dynamical: or, the Conditions and Course of Life of Man* (1856).

Dr. Draper's lasting contributions to physiology and to pure chemistry were few and relatively unimportant. On the other hand, his name is associated with a number of results of the greatest value in physical chemistry, especially in photochemistry (q.v.). The chemical action of light early attracted his attention and for many years formed his favorite subject of investigation. He succeeded in demonstrating that different colors of light have an unequal influence on the decomposition of carbonic acid by the green pigment of plants. The spectra of light emitted by incandescent substances engaged his attention as early as 1847, and his memoirs show that at that early date he had already grasped the wonderful possibilities of spectrum analysis, in both chemistry and astronomy. He further succeeded in showing that

all parts of the spectrum, the invisible as well as the visible ones, are capable of chemical action. His improvements in the art of photography entitle him to an eminent place among the great inventors of the nineteenth century. The principle of photography was established by the Frenchman Daguerre; but Daguerre's process was imperfect and practically incapable of useful application. It was Draper's improvements that rendered it possible to apply photography to the representation of the human countenance, and the first photograph was taken by Draper in 1839, in the old building of the New York University. A valuable collection of Draper's publications was published in 1878, under the title *Scientific Memoirs: Being Experimental Contributions to a Knowledge of Radiant Energy*.

Though a lifelong teacher of science and a prolific writer on scientific subjects, Draper will perhaps best be remembered as the author of three works which more properly belong to the domain of philosophical history. The first of these and the most important is *The History of the Intellectual Development of Europe* (2 vols., 1863), in which he attempts to apply the methods of science to human history and to prove inductively that "social advancement is as completely under the control of natural law as is bodily growth." Much of his data, both scientific and historical, has been superseded, and some of his conclusions are discredited, but the work is characterized by considerable erudition and a remarkable clearness of presentation, and is still much read. His *History of the American Civil War* (3 vols., 1867-70), though it gives a graphic and fairly accurate account of the military operations, is chiefly valuable for its elaborate analysis of the causes, immediate and remote, which made a war between the North and the South inevitable. The most popular of his works, however, is his *History of the Conflict between Religion and Science* (New York, 1874), a candid, philosophical, and fairly comprehensive treatment of the subject. Consult Barker's "Memoir," in vol. ii of the *Bio-graphical Memoirs of the National Academy of Sciences* (1886).

DRAPER, LYMAN COPELAND (1815-91). An American historian and educator. He was born at Hamburg (now Evans), Erie Co., N. Y., and was educated at Granville College (now Denison University), Ohio. In 1840 he conceived the idea of writing a history of the Indian wars of the United States and with this in view visited many pioneers, Indian chiefs, and others who were in any way identified with the early Indian civilization. He continued these investigations for 25 years, traveling thousands of miles through every part of the United States. The information thus compiled is said to have covered a period from about the middle of the eighteenth century to the death of Tecumseh. From 1854 to 1887 he was secretary of the Historical Society of Wisconsin and practically became the founder of the extensive library of that society, which upon his accession was limited to only a few volumes. The results of his extensive tours to collect material on the early history of Wisconsin were published in the first 10 volumes of the *Wisconsin Historical Collections*, which he edited. Unfortunately only a few of the works projected by him were completed at his death. Among those published are *Madison, the Capital of Wisconsin, and its*

Heroes (1857) and *King's Mountain and its Heroes* (1881).

DRAPER, WILLIAM HENRY (1801-77). A Canadian statesman and jurist, born in London, England. As a boy, he ran away to sea to serve on an East Indian ship. He came to Upper Canada when 19 years old, taught school at Port Hope, studied law, and was called to the bar. His professional success, especially before juries, was heightened by a winning presence and persuasive ability as a speaker. In 1836 he was elected a Conservative member of the Upper Canada Assembly and was appointed a member of the Executive Council without portfolio. At that time the Executive Council was not responsible to the Assembly, a condition which had brought the Reformers in Upper Canada to the point of rebellion. (See *POLITICAL PARTIES, Canada*.) Draper had little sympathy with them, his temperament and political principles alike being opposed to an extension of popular rule. In 1837 he was appointed Solicitor-General and in 1840 Attorney-General, but at the request of Lord Sydenham, the first Governor under the Act of Union of 1841, he entered the administration formed under that act as Attorney-General for Upper Canada. His position as member of a cabinet avowedly based upon the newly vindicated principle of responsible government was anomalous, even though the principle at that time was imperfectly understood. Some of his ministerial associates widely differed from him, notably Robert Baldwin (q.v.). Draper found it necessary, first, to represent the Conservative element in a cabinet whose members should have been of the same political complexion; also, to state and defend the conditions on which responsible government could be made acceptable to the Conservative party. The latter task, ably but unsuccessfully attempted, henceforth determined his political course. He soon resigned and in 1842 was appointed a member of the Legislative Council. When Sir Charles (afterward Baron) Metcalfe (q.v.) became Governor, Draper became his chief adviser; but the Governor's firm persistence in autocratic methods left the country without a ministry for the greater part of a year until the more important offices were filled. Draper resigned from the Legislative Council and was elected to the Assembly in order that he might more effectively defend his policy. In 1844 the general elections had been in his favor. He became Premier, but after a trying tenure of office, during which some of his political associates turned against him, he retired in 1847. A long and enviable career of more than 30 years still remained to him as jurist. He was appointed a puisne judge of the Court of Queen's Bench in 1847; in 1856 he became Chief Justice of the Common Pleas, in 1863 Chief Justice of Upper Canada, and in 1869 Chief Justice of Error and Appeal. In 1857 he was sent to England to represent Canada in the negotiations with the Hudson's Bay Company for the transfer of its rights to Canada. His numerous decisions form a judicial record of great learning and authority. Consult Dent: *Canada since the Union of 1841* (1881).

DRAPER, WILLIAM HENRY (1830-1901). An American physician. He graduated from Columbia College in 1851 and four years later from the College of Physicians and Surgeons (Columbia), where he was clinical professor of diseases of the skin from 1869 to 1879. He also

served asian to St. Luke's, Roosevelt, hospitals and as visiting physician to the New York Hospital. Besides being one of the founders of the American Dermatological Association, he was president of the Association of American Physicians in 1888. He published a treatise on dermatology.

DRAPIER LETTERS. See SWIFT, JONATHAN.

DRASCHE, drāsh'e, ANTON (1826-1904). An Austrian physician. He was born at Lobendau, Bohemia, and was educated at Prague, Leipzig, and Vienna. In 1858 he became lecturer on pathology and therapeutics at the University of Vienna, and in 1874 he was appointed extraordinary professor of epidemiology at that institution. During the cholera epidemics of 1850, 1854, 1855, 1866, and 1873 he conducted special hospitals or medical departments for the treatment of patients, and his numerous papers on the treatment of cholera, published chiefly in the *Medizinische Wochenschrift*, are considered valuable contributions to the literature of the subject. He was also an acknowledged authority on diseases of the heart, and the introduction of the tincture of strophanthus into the therapeutics of these diseases is due to his initiative. A collection of his medical treatises was published at Vienna in 1893.

DRAUGHTS. See CHECKERS.

DRAVE, drāv (Ger. *Drau*). An important affluent of the Danube, rising in the eastern part of Tirol, at a high altitude on the south slope of the main ridge of the Hohe Tauern Alps, and flowing through the Pusterthal towards Lienz, where it is joined by the Isel (Map: Austria-Hungary, F 4). It then flows a little south of east through Carinthia and Styria, passing Villach and Marburg; then, turning towards the southeast, it forms the boundary between Croatia and Slavonia on the right and Hungary on the left, and joins the Danube 10 miles east of Esseg, after a course of 465 miles. Its principal affluent is the Mur, from the left. In the first part of its course the Drave is but a mountain torrent, rushing wildly through the craggy passes of Tirol, but from Villach it is navigable for rafts to its mouth, a distance of 380 miles, and for steamers from Bares, about 100 miles from its mouth. The navigation facilities have been much improved by the government. The valleys through which it flows in its course through Carinthia, Styria, and Croatia are distinguished by great fertility and picturesque scenery, while in Slavonia it is frequently bordered by dense forests. In earlier times the valley formed the road through which the invaders from the East—Huns, Slavs, and Turks—penetrated to western Europe.

DRAVIDIAN ARCHITECTURE. A term used by Fergusson and others to designate the Hindu or Brahman architecture of southern India, as seen especially in the temples of Chilambaram, Ramisseram, Madura, Tarpully, Vellore, Perore, Tanjore, Conjeveram, etc., with lofty gopuras (q.v.), corridors, pools, and halls. See INDIAN ART.

DRAVIDIANS (Skt. *Drāviḍa*). The name given to a large group of non-Aryan races of southern India, including those speaking Tamil, Telugu, Kanarese, Malayālam, Tulu, Kudagu, and six or eight uncultivated dialects of the ruder tribes, like Tōda, Kōṭa, Khond, and Gond, together with Orāon and Rājmahāl. The census

of 1901 gives the number of the Dravidian-speaking population as 57,497,982. Geographically the Dravidian population occupies almost the entire peninsular part of India, or that portion to the south of the Vindhya forest and the Nerbudda River, as a glance at the linguistic and racial maps of Cust and Constable will show. (See also INDIA.) The Orāons and the Rājmahāl hill tribes are sporadic representatives of Dravidians in the Province of Bengal to the north. Like the main body to the south, they are remnants left over from an earlier time when the Dravidians occupied a much larger part of India than at present; as a whole, the Dravidian stock has been pushed forward or overrun by the advance of the Aryan incomers from the north. Ethnologically the Dravidians are interesting, especially such a tribe as the Tōdas, in the Nilgiri hills, who represent one of the lowest stages of civilization. In some districts the Dravidians are distinguishable by language rather than by physical characteristics from the neighboring Hindu (Aryan) peoples, while in others they are so dark-skinned and so constituted in hair, features, etc., as to lead some ethnologists to consider them related to the Australians and to group the latter and the former as one race. Some authorities consider the so-called "Kolarian" peoples to be related to the Dravidians, while others look upon them as pre-Dravidian aborigines. The religion of the Dravidians embraces all phases from the rude nature worship of the hill tribes to the borrowed Buddhism, Hinduism, and Islamism of the more civilized peoples. The Dravidians (Tamils) have even developed a style of architecture. The folklore and mythology of some of these peoples is rich and varied, of the Tamils in particular.

The Dravidian languages belong to a group quite independent of the Indo-Germanic (q.v.); the affinities which these tongues show with Sanskrit are due to geographical contact and not to linguistic kinship. Hardly any two of the dozen Dravidian languages are intelligible to those who speak the other, except in a general way. The two which stand highest in cultivation and importance are the Tamil and the Telugu. More than half the number of Dravidian-speaking peoples employ the one or the other of these two vernaculars. The Tamil covers the lower eastern side of the Indian peninsula from Madras to Cape Comorin and over into Ceylon. It is spoken by some 16,525,500 people. The Telugu, which was spoken in 1901 by 20,696,872 persons, adjoins this language to the north and extends from Madras upward beyond the dominions of the Nizam of Hyderabad. The Kanarese, or Canarese, spreads westward from the Telugu district to the sea and is current among some 10,365,047 persons. The Malayālam, spoken by 6,029,304 individuals, runs in a narrow strip down the lower southwestern part of the peninsula, almost from Mangalore to the cape. The language of the Brāhui (q.v.), an Iranian tribe of Baluchistan, seems to belong to the Dravidian group. On the other hand, there is very little evidence in favor of the theory of the affinity of Dravidian to the Burmo-Tibetan and the Australian family of languages.

With regard to Dravidian literature, such works as exist in the several languages are comparatively modern, despite the antiquity of the Dravidian civilization. Hardly one can be said to be more than 1000 years old. The Tamil and the Telugu, in fact, are the only two Dravidian

languages that can be said to have any real literature. Tamil claims to have compositions as old as the legendary sage Agastya, but the treatises and other writings attributed to him can hardly be dated prior to the tenth century A.D. Probably not far removed from the same date is the *Kural* of Tiruvalluvar, comprising poetical aphorisms in 1330 distichs (trans. by Ch. Graul, Leipzig, 1865), and likewise the "Cintāmani," a romantic poem of some 15,000 verses, written by an unknown author, or again the ethical poem "Nālādiyār," which has been rendered into English by Pope (Oxford, 1893). Two centuries later the Tamil poet Kambar made a version, or adaptation, of the Sanskrit epic *Rāmāyana*, and again in the sixteenth century there was a literary revival connected with the name of the poet king Ati-Vira-Rāma Pāndya. At the opening of the eighteenth century we find, besides the native Tamil poet Tāyumānavar, the name of a foreigner, the celebrated Italian Jesuit missionary Beschi, who wrote poetry and prose of so excellent a quality as to win him a place in Tamil literature. In more recent times, it may be added, the educational influences of the Madras College have done much for Tamil through translating into it the English Bible and various religious works, and Tamil may be said to possess a future as a vernacular literature. Second comes Telugu, in which the oldest extant poetical work is a version made from the great Sanskrit epic, *Mahābhārata*, by Nannappa, or Nannaya Bhatta, presumably in the twelfth century A.D. Kanarese may also claim the name of a poetical writer, Keśava, who probably belonged to the same century. In the Malayālam language, moreover, there is a poetical account of Rāma, the heroic Prince of India, based upon the Sanskrit, and there are likewise versions of both the greater Sanskrit epics. The other Dravidian languages possess either no literature at all or none worth mentioning.

Bibliography. The standard books on Dravidian are the large work by Caldwell, *Comparative Grammar of the Dravidian, or South Indian Family of Languages* (2d ed., London, 1875), and Grierson, "Mundā and Dravidian Languages" (in the *Linguistic Survey of India*, vol. iv, 1906); Forsyth, *Highlands of Central India* (London, 1871); Dalton, *Descriptive Ethnology of Bengal* (Calcutta, 1872); Reclus, *Primitive Folk* (New York, 1890); Kingscote, *Folk-Lore of Southern India* (London, 1890); Oppert, *Original Inhabitants of India* (ib., 1893); Baines, "Ethnography, Castes, and Tribes," in Bühler, *Encyclopædia of Indo-Aryan Research* (Strassburg, 1912, with bibliography); Shilotri, *Indo-Aryan Thought and Culture* (New York, 1913); Thurston, *Omens and Superstitions of Southern India* (London, 1912). For the primitive Dravidian civilization, see the articles of J. F. Hewitt in the *Journal of the Royal Asiatic Society*. There is also a considerable special literature for each of the civilized Dravidian peoples. On the Dravidian languages, consult: Cust, *Modern Languages of the East Indies* (ib., 1878); Hulbert, *Comparative Grammar of the Korean Language and the Dravidian Languages of India* (Seoul, 1906); Hunter, *Comparative Dictionary of the Non-Aryan Languages of India* (London, 1868). For Tamil, consult: Pope, *First Lessons in Tamil* (Oxford, 1891), and other works by the same author, including his English translation

of the "Nālādiyār" (ib., 1893); Hultzsch, *South Indian Inscriptions, Tamil and Sanskrit*, trans. (Madras and Leipzig, 1890-95); Graul, *Tiruvalluvar's Kural*, trans. (Leipzig, 1865). On Telugu: Arden, *Progressive Grammar of the Telugu Language* (Madras, 1873); Brown, *Telugu-English and English-Telugu Dictionary* (ib., 1852-54); Carr, *Collection of Telugu Proverbs* (ib., 1868). On Kanarese or Canarese and Malayālam there are several works published in Mangalore, southern India.

DRAWBACK. A term used to designate the repayment of taxes, whether import duties or internal taxes, upon goods which are exported. Drawbacks upon goods imported which are re-shipped in the original packages are rendered unnecessary by the warehouse system, which permits the deposit of goods in bond, without payment of taxes until they are withdrawn either for export or for home consumption, in which latter case the taxes must be paid. If, however, the imported goods are manufactured before the reexportation, drawbacks are necessary if the payment is to be remitted. In the case of goods subject to internal tax the granting of drawbacks on the exportation of the goods serves the purpose of freeing the exporting manufacturer from an increased cost of production through taxation, which his competitors do not have to bear. Great care must be exercised in the mode of assessing the drawback to avoid, on the one hand, taxation and, on the other, a bounty upon exportation. If the amount of the drawback is greater than the tax paid, it becomes a direct encouragement to exportation, which may not be contemplated by the law. It is in this way that the so-called sugar bounties in Germany and some other continental countries arose.

In the United States drawbacks are allowed on imported articles exported for sale abroad, and on firearms, agricultural implements, etc., made of foreign iron, steel, stocks and handles of wood grown in this country, provided the imported materials exceed one-half of the value of the whole material used. Every one entering merchandise for importation or exportation with right of drawback is required to deposit the original invoice of such merchandise with the collector, who causes an inspection to be made by the proper officer and the articles to be compared with their respective invoices before granting the permit for lading. No drawback is allowed on merchandise entitled to debenture under existing laws unless it be exported within three years from the date of importation. Drawbacks are also admitted for the exportation of distilled liquors and manufactured tobacco on which internal-revenue taxes have been paid.

DRAWBRIDGE. See BRIDGE.

DRAWING (from *draw*, AS., Goth. *dragan*, Icel. *draga*, to drag, probably connected with OHG. *tragan*, Ger. *tragen*, to carry). The delineation of form upon a given surface, usually plane, by means of lines and tints or shades. Painting and drawing are broadly distinguished by the use of varied color in painting, reproducing the colors of the object represented, while in drawing only the form and light and shade (or "modelling") are represented. The forms delineated may be visible objects, forms imagined and presented as if actually seen, or purely arbitrary or abstract forms, as in ornamental patterns and mathe-

matical ". . . . As the delineation of form lies at the foundation of all the plastic arts, drawing is the most important single branch of study in schools of art and of engineering. Since, moreover, the study of drawing trains the faculties of observation and memory to a high degree and develops an effective coordination of the action of hand and eye, it has come to be recognized as of the highest educational value in any system of mental discipline. It is therefore systematically taught in the public schools of nearly all countries that make any pretensions to a well-organized educational system.

The drawing of visible objects is really the graphic recording of mental impressions received through the eye. The draftsman seeks to produce upon the paper, by means of lines and tints, visual images which shall awaken in the beholder mental images and impressions as nearly as possible like those evoked directly by the objects represented. But, since the limitations of drawing in black and white on a plane surface forbid the complete presentation of all the visible facts and aspects of the original object, it is evident that the desired mental impression must be produced largely by *suggestions*, which stimulate the beholder's imagination to supply whatever is lacking in the representation. The drawing, in spite of being merely, e.g., an aggregation of black lines and dots on white paper and but an inch or two in height and width, may so visibly suggest the outline, foliage, masses, light, and shade of a tree, that it evokes in the mind the impressions one experiences in seeing such a tree, and the imagination at once supplies the size, distance, detail, and color which the drawing lacks. Artistic power in drawing consists largely in the ability thus to create by suggestion a vivid impression of reality. A *sketch* is a drawing which attempts to present in a summary way only partial and momentary aspects of the thing represented. An effective sketch is one in which the simplicity and vigor of the artist's personal interpretation of what he sees has not been sacrificed in the effort after elaborate finish. The judicious choice of what to show and what to omit calls for a highly developed taste and can be mastered only by long experience. A master's sketch is worth a score of highly elaborated drawings by 'prentice hands.

Free-Hand Drawing. Drawing in which the hand receives no assistance from mechanical appliances is called free-hand drawing. It lies at the foundation of all the arts of plastic design, sculpture not excepted, and constitutes an art in itself. Its greatest masters, like Raphael, Leonardo da Vinci, and Michelangelo, have been among the geniuses of their times. Even the greatness of such colorists as Titian and Veronese depends in large measure upon their consummate draftsmanship. See PAINTING.

The restrictions under which the artist labors in seeking to represent in black and white upon a plane surface the multitudinous aspects of visible objects have already been referred to. The different kinds and schools of drawing are distinguished by the ways in which these restrictions are evaded or overcome. In outline drawings and in some sketches, only the exterior outlines and contours or salient edges and markings of an object or scene are shown. The power which these may have of evoking

complete mental pictures is indicated in the simple outline drawings on Greek vases and by black silhouettes of faces and figures. The power of pure line, even divested of accompanying color, to suggest the most varied modeling of surfaces and to express the minutest detail is admirably exemplified in Chinese and Japanese art. The European schools, on the other hand, lay great stress upon *values*, or the rendering of the varied luminosities and gradations of light and dark in the objects represented, by corresponding gradations of the tones of the drawing; i.e., of the mixtures of black and white produced by the use of the pen and ink, pencil, crayon, charcoal, or sepia brush upon the paper. Even different colors may be to a certain extent suggested, or rather interpreted, in black and white by a careful rendering of their apparent values; a dark red, e.g., being indicated by darker shading than a light blue or a yellow. The great artists of the Renaissance stand midway between the Japanese exponents of pure line and the modern European interpreters of values. Their drawings are wonderful for the purity, vigor, and delicacy of their lines, as well as for the skillful though somewhat conventional rendering of the forms as expressed by
LINE; IMPRESSIONIST SCHOOL OF PAINTING.

Technic of Free-Hand Drawing. The fundamental principles of the art are the same, whatever the medium employed. Good drawing demands, first of all, a trained sense, of form, i.e., the power to observe, to understand and appreciate, to remember, and to represent, form in general; or, in other words, the mastery of proportion. In drawing from any object or model the first essential is to observe, and sketch in, the dominant structural lines, contours, and masses, including the conspicuous high lights and deeper shades and shadows. The more important details are next added and corrected, and the minor details are left to the last. In executing these various stages of the drawing lightness of touch and sureness of line are important qualities, attained only by long, and patient discipline. Taste and imagination are both exercised in the choice of what to show and what to omit, while experience alone endows the artist with the knowledge of the most effective methods for expressing the facts and aspects he is seeking to record.

But the detailed technique of drawing varies greatly with the medium employed. The chief instruments are the pencil, pen, black crayon, charcoal, and brush. Of these the pen is the most exacting, since it makes an absolutely black mark on the white paper, and tints must be expressed by dots, closely serried lines, and crosshatching. The masters of pen drawing are invariably masters of pure line. With charcoal or crayon sauce the artist must, as it were, paint on his paper, fine lines being out of the question; so also with the brush, in sepia and other "wash" drawings. The pencil and crayon occupy a middle ground, requiring the use of the line, but permitting broad, soft strokes and stumped or rubbed-in shading. Very effective drawings are made by using a tinted paper—gray or pale blue—on which the high lights are laid on in white with chalk or Chinese white, and the darker shades and masses with the pencil, while the tone of the paper is left to represent the intermediate values. The great masters of the Renaissance,

lacking the "lead" or plumbago pencil, which is a modern invention, used the lead point or a silver point on parchment or heavy paper, giving pale gray line; or, more often, sanguine or red chalk. The quill took the place of the modern steel pen, making a softer and broader stroke.

Instrumental Drawing. For scientific purposes, for the working drawings from which buildings and machinery are to be made and erected, and for all purposes requiring great exactitude of representation, a different sort of delineation is necessary from that of the artist working with free hand. Free-hand drawings are personal interpretations of visible form; in this lies their charm. Their value is artistic, not scientific; no two drawings of the same object by different persons, or by the same person at different times, can be absolutely alike. In *mechanical* or *instrumental* drawing, on the other hand, mathematical exactness of line and dimension is secured by the use of various instruments, the most important of these being the T-square, rule, and triangles, used in drawing right lines; compasses for drawing circles and arcs of circles; dividers for laying off exact distances, the scale for determining and measuring dimensions, the protractor for laying off angles, and the ruling pen for drawing clean and faultless lines in ink; besides a considerable number of special appliances which cannot here be enumerated. The object of drawings executed by these means is not to present the aspects of objects as we see them, but to furnish scientifically correct graphic records of the actual proportions and form relations of objects, usually at a much reduced scale. This is effected by means of *projections* upon imaginary vertical and horizontal planes, called *planes of projection*, two dimensions of the object being shown in each projection. These projections comprise *plans*, or top views, showing the object as if seen from an infinite height above; *elevations*, or front, side, and rear views, as if seen from a point infinitely distant horizontally; and *sections*, which show the object as if sliced in two and the nearer half removed, exposing the interior structure. These projections show the correct geometrical relations of the various dimensions and parts of the structure or object, and by the use of two or more projections all its dimensional relations are exhibited. To assist the eye in interpreting these highly conventional drawings—which are really not pictures, but diagrams—they are often (especially in architectural drawings) made with the shadows cast as if by sunlight, falling on the object in each projection at an assumed and uniform angle. This angle is usually so taken that the rays, falling from in front of the vertical plane, downward to the right, are projected at 45° to the ground line on either projection. The delineation of these conventional shadows is a branch of descriptive geometry and has received the name of *sciography* ("shadow writing").

Instrumental drawing is divided, according to its various applications, into *mechanical* drawing, a general term for all engineering drafting; *machine* drawing or the preparation of the working drawings for the construction of machinery; *architectural* drawing, *ship drafting*, *topographical* drawing, etc.; and the various purely mathematical divisions of *descriptive*

geometry, *stereotomy*, or the preparations of drawings for cut stonework, *crystallography*, and the like.

In architectural drawing and in most forms of machine drawing and engineering the purpose in view is to furnish diagrams of all parts of a structure or machine to be erected, drawn to exact scale and marked with the proposed dimensions, for the guidance of those who are to execute the work. For this purpose there are prepared as many plans as may be necessary, elevations of the various faces of the structure, and sections showing its internal arrangement. These are all drawn to a small scale, which may be from $\frac{1}{32}$ of an inch to the foot to $\frac{1}{4}$ or even $\frac{1}{2}$ of an inch to the foot (with approximately corresponding scales where the metric system is used). Many of the details of construction are shown in drawings to a larger scale, 1 foot being represented by $\frac{3}{4}$ of an inch, 1 inch, or even 2 or 3 inches; and there are also prepared a large number of drawings of structural details of the full size of the intended work. At the mills, stoneyards, and shops where much of the work is executed, these drawings are supplemented by *shop drawings* prepared by the several contractors to assist in laying out the work and to serve as exact patterns for its execution. The largest shop drawings are those made in the mold lofts of the shipbuilders, each rib being drawn out to its full size on the smooth floor of the loft. The drawing of decorative details of carving, inlay, and other ornament in architectural work is of necessity chiefly free-hand work and involves an artistic element not called for in the purely scientific drawings above described.

Perspective Drawing. Perspective drawing stands midway between free-hand or pictorial drawing and instrumental drawing, since it aims to represent the actual aspect of an object from a given point of view, and yet to do this is a matter less of personal and artistic interpretation than of scientific determination. The object is shown with all the angular distortion and foreshortening which it exhibits to the eye placed at the given point of view; but the exact angles, dimensions, distortions, and foreshortening of each part are determined by mathematical processes and not by mere visual impressions. It thus forms a department of descriptive geometry, but the object is represented, not as projected by parallel lines on two planes of projection, but as projected, by rays converging to the eye, upon an assumed picture plane (or rarely upon a cylindrical or even spherical surface) intersecting these rays and represented by the paper. The picture is absolutely correct only for the eye placed at the given point of view. All parallel lines not parallel to this plane are shown converging to points called *vanishing* points, and parallel planes in like manner converge towards vanishing lines or *traces*. These are all determined by rules and processes too intricate to be here detailed. (See PERSPECTIVE.) There is also a form of angular projection called *isometric* projection, which shows all three dimensions at once, as does a perspective drawing, but with a uniform scale for all parts of the picture, while in true perspective the same actual dimension appears of varying size according to its distance from the eye.

A perspective drawing, thus scientifically laid out as to its outlines, may be finished, as to

line, color, light and shade, and accessories, in a pictorial and artistic manner, as in free-hand drawing; it then emerges from the category of scientific drawing into that of fine art. Indeed, no artist can master the correct portrayal of form, especially of scenery and buildings, without training in perspective; it is accordingly an important branch of study in all schools of art. It is absolutely indispensable to the scene painters and forms the basis of the illusory effects of the stage setting. The artists of the Renaissance were the first to reduce its principles to system, and many of them were carried away by the fascination of its possibilities; the later artists, especially the Venetians (notably Paolo Veronese and later Tiepolo), and the artists of the 18th century employed its resources with great effect; in their great decorative paintings. Japanese drawings are interesting for their treatment of perspective, the point of view being in almost all cases assumed at a high elevation, giving an approximation to the effect of what is called "bird's-eye perspective."

The Teaching of Drawing. The delineation of an object actually seen involves, first, *observation*, which comprises perception and attention; secondly, the memorizing or mental *retention* of the visual impression while the eye is momentarily withdrawn from the object to the paper; and thirdly, the *coordination* of the movement of the hand with the outlines of the memorized image. In drawing imaginary forms or designs originating in the artist's mind, a mental image takes the place of the visible object, and imaginative and creative power—the ability to visualize clearly and distinctly in the "mind's eye" these mental images—is an important element in all draftsmanship of the highest order. Skill in drawing is thus in quite as large measure dependent on intellectual factors as on skill of hand, and no system of teaching drawing which confines itself to the mere discipline of hand and eye can be considered as scientifically or philosophically correct. The draftsman draws best what he *knows* best, because well-known forms are those most easily and clearly visualized, so that a thorough acquaintance with the widest range of forms is as essential to consummate draftsmanship as is manual skill in portraying them. Thus it is that constant drawing from life, from nature, from the object, not only gives facility of execution, but, by enlarging the range and increasing the thoroughness of the artist's knowledge of forms, gives him greater resource and a broader grasp of form in general.

Modern systems of teaching drawing to children in the schools generally recognize these principles. The earliest work in the kindergarten and primary grades is such as to stimulate the imaginative and picturing faculty of the child, while he is trained by modeling and weaving into familiarity with the more elementary forms of common things. In subsequent grades the powers of accurate observation are cultivated and disciplined, while manual dexterity is imparted almost insensibly by varied exercises in drawing from leaves, flowers, and still life, and from "flat copies" of ornament forms. In the higher grades drawing from the east, from the antique, and from the living model, in various media, such as charcoal, India ink, and crayon sauce, gives flexibility to the student's powers of artistic ex-

pression and trains his taste in the selection of what to represent and what to reject in his graphic interpretation of what he sees. He is also taught a proper *method*, or procedure, in the making of . . . and learns the correct use of . . . and block outlines, the importance of securing accuracy in the masses before attempting details, and other like principles of correct delineation. In parallel courses, usually in connection with manual training, he has also been taught the elements of mechanical drawing. All these exercises are invaluable for imparting the power of quick, comprehensive, and accurate observation, precision of eye measurements, and dexterity of hand—endowments all of which are useful in the affairs of life, quite apart from any direct application to the fine arts. The detailed methods and sequence of the instruction vary greatly in different systems. Some dwell especially upon nature study; others emphasize the development of form memory; others again make large use of the forms of classic ornament to train at once the eye, the hand, and the taste. In the art schools generally the pupil begins by drawing from the flat copy, then takes up drawing from the antique, i.e., from casts of antique sculpture, and, finally, enters the life class, in which he draws from both nude and draped living models. The criticism has been made that in too many of these schools the teaching follows the routine of apprenticeship methods and lacks philosophical analysis and progressiveness; but this doubtless is not true of the most advanced among them.

Bibliography. Among the more important works on drawing are: Ruskin, *Elements of Drawing* (London, 1857); Pennell, *Pen Drawing and Pen Draughting* (ib., 1889); Maginniss, *Pen Drawing* (Boston, 1889); Ware, *Modern Perspective* (New York, 1895); Spiers, *Architectural Drawing* (London, 1888); also the interesting *Album de Villard de Honnecourt*, ed. by Lassus (Paris, 1858); *Cyclopedia of Drawing* (Chicago, 1905). For the teaching of drawing, consult: Clarke, "Drawing in the Public Schools," *Report of the United States Bureau of Education, Circular of Information No. 2* (Washington, 1874); Viollet-le-Duc, *Learning to Draw* (Eng. trans., New York, 1886); Tadd, *New Methods in Education* (ib., 1899); Hatton, *Figure Drawing and Figure Composition* (ib., 1905); Dodgson, "Art for Schools in the Reign of George III," in the *Connoisseur* (1903); *Memorial of the Teaching of Drawing, Scotch Education Department* (London, 1907); Haney, *Art Education in the Public Schools of the United States* (ib., 1908); Norton, *Freehand Perspective and Sketching* (Brooklyn, 1909); Dow, *Composition* (New York, 1910); Speed, *Practice and Science of Drawing* (ib., 1913). For mechanical drawing, consult treatises of Anthony (Boston, 1903); Bartlett (New York, 1903); Jamison (ib., 1904). See PERSPECTIVE; LINE.

DRAWING BOARD. A board on which drawing paper is strained for painting in water colors. The paper is wetted for the purpose of being strained, and, when attached at the edges, it is permitted to dry and contract. Formerly the drawing board was fitted into a frame, the edges of the wet paper being made fast by the pressure of the frame on the board. But the much simpler drawing board which is now in use is made of a flat piece or pieces of wood, held together and prevented from

warping by an edging of other pieces, the grain of which runs in the opposite direction. The wet paper is attached to the edges of the board with paste or thin glue and, when dry, becomes perfectly firm and flat. The same kind of board is used for charcoal or crayon drawing, in which case the paper is merely pinned to the board.

DRAWPLATE. A hardened steel plate with a graduated series of holes, through which ductile metals are drawn in making them into wire. See **WIRE**.

DRAYTON, MICHAEL (1563-1631). An English poet. He was born in Hartshill, in Warwickshire. Of the events of his life but little is known. He was a page probably in the household of Sir Henry Goodere, of Polesworth, to whom he was indebted for his early education. In 1591 he was in London, although under James he failed in efforts to gain the royal favor. He began his literary career with a metrical rendering of parts of the Bible called *The Harmony of the Church* (1591). The volume was condemned by the authorities, and all but 40 copies of the edition were destroyed. This was followed, in 1593, by nine eclogues with the title *The Shepherd's Garland*, and in 1594 by a series of sonnets, in which was celebrated some unknown woman, under the name *Idea*. Drayton's famous sonnet ("Since there's no help, come let us kiss and part") belongs to a later period. *England's Heroical Epistles* (1597) was a successful imitation of Ovid's *Heriodes*. In 1603 appeared a long historical poem, called *The Barons' Wars*, parts of which in another metrical form had been published seven years before. Some of Drayton's very best work—as the *Ballad of Agincourt*—is contained in *Poems, Lyrical and Pastoral* (about 1605). For many years he had been at work on a long It was published under the (first installment 1613; complete, 1622). Though monotonous as a whole, it contains fine passages. Drayton opened a new vein in the fairy poem *Nimphidia*, one of a collection of poems published in 1627. This new vein was further worked in the 10 *Nymphalls*, in the *Muses' Elysium* (1630). His *Complete Works* were published in 1748. He also collaborated in Though much of his work is he wrote many choice poems. We have nothing more dainty than his fairies and no finer martial ballad than his *Agincourt*. He was buried in Westminster Abbey. The Spenser Society has reprinted *Poems of 1605* (1885-87); *Poems, Lyrical and Pastoral* (1891); *Poly-Olbiion* (1890); *Muses' Elysium* (1892). Consult: selections from the *Poems*, by Morley (London, 1878); by Bullen, privately printed at Chilworth (1883); by Brett (Oxford, 1907); Elton, *Introduction to Drayton* (Manchester, 1895); id., *M. Drayton: A Critical Study* (London, 1906).

DRAYTON, WILLIAM HENRY (1742-79). An American Revolutionary patriot. He was born on the family estates in South Carolina, went to England in 1753, with Charles Cotesworth Pinckney and Thomas Pinckney, was educated at Westminster School and at Balliol College, Oxford, returned to South Carolina in 1764, and soon afterward was admitted to the bar. In 1765 he was elected to the Assembly, in which he opposed the nonimportation agreement. In 1769 he wrote, under the signature "Freeman," a series of letters against the "pa-

triotic associations" of the time, which he charged with encroaching on private rights; and largely on this account he was appointed privy counselor for South Carolina in 1771 and assistant justice in 1774. In the latter year, however, he published a vigorous antiministerial pamphlet, entitled *A Letter from "Freeman" of South Carolina to the Deputies of North America, Assembled in the High Court of Congress in Philadelphia*, and for this he was removed from his positions as counselor and judge. He was President of the Council of Safety and of the Provincial Congress of South Carolina in 1775; was made Chief Justice of the State in March, 1776; and in April, 1776, virtually proclaimed the independence of South Carolina on the ground that King George III, having violated American rights, had "by the law of the land . . . abdicated the government," and henceforth had "no authority" in the former Colony. He was acting President of the State for a short time in 1777, during the absence of John Rutledge, and from 1778 until his death was a prominent member of the Continental Congress. He wrote a number of powerful pamphlets and planned a history of the Revolution. A large part of his manuscript was destroyed on the ground that it contained important state secrets, but two volumes survived, covering the history of the Southern Colonies between 1773 and 1776, and these subsequently served as the basis for a work by his son, John Drayton (Governor of South Carolina in 1800-02 and 1808-10), entitled *Memoirs of the American Revolution Relating to the State of South Carolina* (Charleston, 1821).

DREAMING (from *dream*, OS. *drōm*, Icel. *draumr*, OHG. *troum*, Ger. *Traum*, dream; probably connected ultimately with OHG. *triogan*, Ger. *trügen*, Skt. *druh*, to deceive, OPers. *drauga*, a lie). In the profoundest sleep there is, so far as we can tell, a total lapse of mentation; the conditions of the formation of a consciousness are not realized. There has been, it is true, much dispute as to whether the mental life is ever really extinguished in sleep; and we cannot deny the possibility of a continuance of bare organic sentience, which is lost, on waking, in the richer ideation of the normal consciousness. But, however that may be, introspection gives us no psychological warrant for the assumption of mental process during deep sleep. In the lighter stages of sleep, on the other hand, there is intermittent mentation; we "dream," and the dream consciousness is in large measure accessible to our analysis.

It is probable that dreams, in the great majority of cases, are started by the stimulation of some sense organ and do not take their origin within the brain itself. We may darken our bedroom as we will, but we cannot rule out the "intrinsic gray" or "light dust" of the retina; nor the throbbing and buzzing of the blood circulation in the ear; still less can we eliminate cutaneous and organic stimulations. There is, then, always the possibility of a sense impression finding its way to the brain during sleep. If, now, we keep our eyes closed as we wake from a visual dream, we can often trace the dream pattern in the light dust that is seen upon the field of the closed lids; while, conversely, if we note the pattern of the light dust before we fall asleep and then have ourselves waked, we find that the dream has taken its

form and character from the peripheral excitations. Here is clear evidence that the brain has received its dream cue from the eye. Similar tests have been carried out, with similar though less striking result, upon the other sense organs. As a general rule, then, the dream consciousness seems to be started by some sensory stimulus, though, having once originated, it may continue its course in obedience to the laws of association (q.v.) without any further interference from the outside.

We have supported this conclusion by an appeal to the eye; and the appeal has doubtless appeared quite natural. For dreams are predominantly visual—so strongly visual, indeed, that it is not rare to find them defined, in so many words, as “trains of fantastic images.” There is good reason for this preponderance of visual mind stuff in dreams. 1. Most of us in the waking life are likely to think, imagine, and remember in visual terms; we are “eye-minded.” It is evident that this ingrained habit of mind towards visualization must show itself in dreams. 2. The retina is in a constant state of intrinsic excitation during sleep; the retinal gray and the light dust will, if only the chance be given them, make themselves known in sensation. 3. And the chance must be given them fairly frequently. For sight is the first sense to disappear, as sleep comes on, and the last sense to be regained on waking; so that the eye may be stimulated during sleep with a moderately high degree of intensity, while the sleeper is still not disturbed. Dreams, however, are by no means exclusively visual. Next in order of frequency to dreams of sight stand, perhaps, the dreams whose principal material is organic and temperature sensations. It is curious to note that dreams which are initiated by an organic sensation (a pain, a suffocation, a cramp) are oftentimes translated into terms of vision. A slight intercostal pain may be dreamed of “in kind” as a dagger thrust or the bite of a mad dog; but we shall probably see the dagger and the dog—and in many cases these will be the main objects of the dream, the organic sensation being present merely as a vague discomfort. So the rhythm of breathing may be “seen” as a flight of birds or of angels; and an irritation of the skin may be “seen” as a host of caterpillars or beetles crawling over us. This fact of translation into the language of sight has done much to divert attention from the very common occurrence of organic sensation in the dream life. In the third (or, as some authors would say, in the second) place come dreams of hearing. Conversation is the one form of external stimulus that in everyday life approaches the visual stimuli of our surroundings in regularity and insistency, and fragments of conversation are the most frequent auditory constituents of dreams. Sounds like the humming of bees and the clatter of musketry—the dream interpretations of the intrinsic noises of the ear—follow next in order. Tonal or musical dreams occur, but are rare. Finally, the senses of smell, taste, and cutaneous pressure may and do contribute elements to our dreams; but these elements are extremely liable to visual translation and appear but rarely in pure form.

The dream consciousness is not confined, of course, to sensations, perceptions, and ideas. Every mental formation that is found in the waking life may be represented (or simulated)

in the dreaming state. Thus, the presence of emotion in dreams—surprise and excitement, fear and shame, disappointment and anger, jealousy and perplexity—is a matter of experience. Indeed, the appearance of emotion follows almost as a matter of course from the large part played in dreaming by the organic sensations. (See FEELING; EMOTION.) We have, further, frequent instances of passive memory, i.e., of the recognition of persons or places—recognitions which our waking consciousness not seldom declares to be false recognitions, but which none the less have the true cognitive form and “feel”; of active memory, efforts of recollection; of passive “supplementing in idea of the . . .” (seeming) perception; of active imagination, e.g., the writing of poetry; of resolve and voluntary endeavor; and of active attention. In illustration of the latter we may take the following dream: “I was trying to find the name of a philosophical writer which I knew began with D. I ran through the index of the book I held in my hand, but could not find the name. Then I went to the shelf, took down another book, and ran through its index in the same way, with successful result.” So far, indeed, may this reproduction or simulation go that we sometimes dream that we are dreaming. We say, in ordinary life, “The whole thing seemed like a dream”; and the same experience of dream-likeness reoccurs in the dream consciousness.

We have spoken of the “reproduction or simulation” of mental formations. Our dream poetry, if it be really composed during sleep and not in the half-waking state before complete arousal, is neither rhyme nor reason; the foreign languages that we speak so fluently in dreams are unfamiliar to us in the waking life; our dream resolves are ineffective; our dream recognitions, as we have said, are oftentimes false. These observations have led to the theory that the dream consciousness is composed, in reality, of a mere panorama of images; and that the complex mental formations which seem to occur in dreams are really imaginary. There is, however, no cause for going behind the clear verdict of introspection. The formations occur; but, owing to the extreme limitation and irregular distribution of attention in the dreaming state, they show characteristic differences from the corresponding formations of the waking life.

Here, indeed, is the crucial problem that the dreamer presents to psychology. The arrangement of the dream is fantastic and disorderly; yet, as the dream comes, we accept its events and incidents unquestioned, taking everything for granted. How are we to account for these seemingly opposed facts? 1. The fantastic nature of the dream is explained by the almost unrestricted freedom of association in the dream consciousness. Our waking consciousnesses are regulated by pressure of outside circumstances. In dreaming, as in reverie, there is a practical absence of regulation: an idea of our childhood is as likely to arise as an idea of yesterday; the sequence of ideas may be logical, but may also be determined by the most trivial and irrelevant of connecting links. As a rule, the fundamental things of mind (space perception, personal identity) remain; but even these may undergo dissociative changes. Association is uncontrolled and has free play. 2. On the other hand, dream ideas are intensive and impressive. The sleeping brain is generally inexcitable;

when, however, an excitation makes its way to the cortex, the result is out of all proportion to the intensity of stimulus. It is as if the active part of the brain drained the inactive part of a portion of its stored energy. Moreover, the scenes in a dream come always in single file. Consciousness has nothing of the "thickness" and complexity, the wealth of "fringes" and marginal elements, that it has in waking. The part of the brain stimulated is a strictly local area; the greater part of the cortex is still quiescent. Now, this narrowness of consciousness means that we have no means of comparing the dream event with the data of our past experience; the event does not fall into relations, but stands alone. But an idea which is at once impressive and uncontradicted is, of course, accepted and believed. Hence is it that the dream, despite its absurdity when recounted in the normal environment of the waking life, provokes no scruples or hesitations as we dream it.

Primitive belief and popular superstition have always tended to ascribe importance and meaning to dreams, although, needless to say, without the justification of a systematic gathering of facts. (See DIVINATION.) Of late years, however, the interpretation of dreams has been placed by the work of S. Freud (q.v.) upon a more scientific basis. Freud was led to the study of dreams through their observed relation to certain other abnormal states, notably to hysteria (q.v.). He holds that a single method is adequate to the interpretation of dreams and to the explanation of hysteria: the method of "psychoanalysis," which consists essentially in eliciting and evaluating as many as possible of the ideas associated in the subject's mind to the ideas of the dream or of the hysterical complex. According to Freud, dreams represent the fulfillment of wishes. In the dreams of children the wish is undisguised and the representation is direct. Adults, however, remain even in sleep under the pressure of a social training to repress and censor the expression of certain wishes (especially those of a sexual nature), so that the wish can be represented in the dream only in symbolical or, so to say, allegorical form. The ideas set up by the peripheral excitations mentioned above thus constitute a "patent content" which disguises, though it cannot wholly conceal, the "latent content" of some definite wish fulfillment.

Freud, *The Interpretation of Dreams* (New York, 1913).

DREAM LIFE: A FABLE OF THE SEASONS. A series of sketches by Donald G. Mitchell (1851), a companion volume to his *Reveries of a Bachelor*.

DREAM OF EU'GENE A'RAM, THE. A poem by Hood (1829), detailing an imaginary dream narrated by Eugene Aram (q.v.) in making confession to a child of the murder of Clark.

DREBBEL, CORNELIS VAN (1572-1634). A Dutch inventor. A peasant by birth, he won the favor of the emperors Rudolph II and Ferdinand II, and of King James I of England. The last 14 years of his life were spent in Lon-

don, where his discoveries in new processes for dyeing wool and silk (afterward used by the founders of the Gobelin manufactures), and his clever inventions, among them a compound microscope and a machine for perpetual motion, gave him the reputation of being a sorcerer. Drebbel has left two treatises, published in Dutch (1608), in Latin (1621), and in French under the title *Deux traités: De la nature des éléments; De la quintessence* (1673).

DREBER, drä'bër, HEINRICH, called FRANZ DREBER (1822-75). A German landscape painter, born at Dresden. He studied at the Dresden Academy and under Ludwig Richter and finally—as the stipendiary of the Dresden Academy—at Munich and at Rome, where he joined the group of painters under Reinhart and thereafter resided. His paintings, which were not appreciated during his lifetime, are distinguished by fine and delicate color and poetic conception. He frequently introduced antique figures and folk scenes into his landscapes. Among his best productions are: "Autumn in Sabine Mountains," "Landscapes with Ruins," and about 500 drawings in the National Gallery, Berlin; "Good Samaritan" (1848, Dresden Gallery); "Sappho" (Schack Gallery, Munich); "Evening Voices" and "Landscape of the Campagna with Washerwomen" (Gallery St. Luca, Rome). Although Dreber led a very retired life, he undoubtedly influenced such painters as Buecklin and the younger Preller.

DRED. A novel by Harriet Beecher Stowe (1856), exposing the conditions of the Southern slave system. The title character is a fugitive slave. A new edition appeared, 10 years later, entitled *Nina Gordon*.

DREDGE (assibilated form of *drag*, AS., Goth. *dragan*, Icel. *draga*, OHG. *tragan*, Ger. *tragen*, Eng. *draw*, *drag*). Any device for removing and bringing up solid substances or material from under water. The simplest form of dredge is that used by oyster fishers, which consists of a strong bag or net whose mouth is kept open by a metal ring, and which is operated by hand by means of a long pole to whose end it is attached. The deep-sea dredge used by scientists for collecting samples of the sea bottom, with its plant and animal life at great depths, is a device similar in its general construction to the oyster dredge, but is, of course, attached to a long wire cable and operated by being dragged along the bottom until filled. (For illustration and description, see DEEP-SEA EXPLORATION.) In engineering a dredge is an excavating device employed in deepening channels and harbors, removing submarine obstructions, such as shoals and bars, raising gold-bearing sand, and for general excavating operations under water. Dredges may be divided into several classes, the principal of which are dipper dredges, ladder (or elevator) dredges, and hydraulic-suction dredges.

The Dipper Dredge is similar in its construction to the ordinary steam shovel, except that the platform carrying the machinery consists of a barge instead of a car. In the ordinary dipper dredging machines a mast or A-frame is mounted on the front end of the barge and serves to support the top end of an inclined boom whose bottom end is pivoted to a suitable casting on the deck of the barge, so that it can swing partially around like the boom of a derrick. Between the two parallel timbers of this boom is inserted a long timber carrying at its outer end a dipper or scoop open at the top and

DREDGES

1. OSGOOD CLAM SHELL DREDGE. This dredge has a bucket of ten cubic yards capacity, and digs to a depth of 80 feet.

2. OSGOOD DIPPER DREDGE. The dipper carries 15 cubic yards of material, and works in depths up to 50 feet.

DREDGES

1. SUCTION DREDGE USED ON PANAMA CANAL. PASSING THROUGH GATUN LOCK
2. LADDER DREDGE "COROZAL" USED ON PANAMA CANAL. BEACHED ON PERICO ISLAND FOR REPAIRS

closed by a door at the bottom. By means of suitable mechanism this dipper is thrust down to the bottom and given a scooping motion which fills the dipper; the next operation is to raise the dipper and by swinging the boom to one side bring it over an auxiliary barge, when the latch holding the bottom door is unlocked and the contents of the dipper are dumped into the barge. By successive operations these operations the bottom is excavated to such a depth as may be desired. To resist the digging thrust of the dipper, the scow is provided with vertical timbers or spuds, which can be thrust down into the bottom and so prevent the barge from moving. Dipper dredges are more extensively used in America than in European countries. The largest dipper dredges in existence are the two 15-cubic-yard dredges put in service in 1914 on the Panama Canal, to be used there for permanent maintenance of channel depth. The hull of these dredges, which are in duplicate, is of steel, approximately 136 feet long, 44 feet wide, drawing $15\frac{1}{2}$ feet of water. They are driven by tandem compound steam engines which operate the dredging as well as the propelling machinery. Each dredge has two interchangeable dipper buckets of 15 and 10 cubic yards' capacity respectively, and the dipper handle is an Oregon fir stick 72 feet long. These dredges can operate at a depth of 50 feet of water.

Another form of dredge, known as the Grapple Dredge, is constructed much like the dipper dredge in respect to the barge, A-frame, and boom; but instead of a dipper the excavating device proper is a grapple which is so suspended from the end of the boom that it can be lowered to the bottom and raised with its load. One of the most common forms of grapple is the clamshell, which consists of two parts hinged together much like the two parts of a clamshell. The mechanism which raises and lowers the grapple also serves to open and close its jaws. In operation the grapple, with its jaws open, is lowered to the bottom, into which its weight causes it to sink partly; the jaws are then closed and thus grasp a quantity of material, which is raised and discharged into a scow by opening the jaws again. When the material to be excavated is hard, the grapple is provided with teeth, and, when so equipped, it can be used to excavate loose rock. Sometimes the grapple consists of several sectors of a sphere, when it is called an orange-peel bucket. One of the largest grapple dredges ever built was designed for use in constructing the Buffalo (N. Y.) trunkwater. The hull was of wood, 120 feet long, 40 foot beam, and $12\frac{1}{2}$ feet deep, with a false bow and stern to make it tow more easily, which increased the total length to 160 feet. The A-frame was 50 feet high, and the boom was 65 feet long. The bucket was of the clamshell type, with a capacity of 10 cubic yards and weighing 15 tons. At Buffalo, N. Y., this dredge worked in water 65 feet deep, and loaded 10 or 11 scows of 400 cubic yards' capacity in 10 hours.

The Ladder, or Elevator, Dredge consists of a hull for the support of the excavating machinery much like the hull of the dipper or grapple dredge; but the excavating mechanism is essentially different. An elevated structure on the hull carries a long girder whose top end is hinged horizontally to the top of the framework, and whose other end extends down through

a wellhole in the hull to the bottom of the water. There is a sprocket wheel at each end of this girder, over which a flexible endless chain is made to run by power applied to the upper sprocket wheel. At intervals along this chain are attached scoop buckets, which of course travel with the chain. As each bucket reaches the bottom of the girder, which is in contact with the bottom of the channel being excavated, it scoops up a portion of the material and carries it to the top of the girder, where the load is discharged as the bucket passes over the upper sprocket wheel. The buckets discharge into chutes leading to scows moored alongside or to a conveyor system of the dredge itself. Sometimes the girder, with its chain of buckets, is arranged to pass over one or both sides of the dredge hull instead of through an inside well. The Panama Canal dredge *Corozal* is the largest machine of this type. It is housed in a hull 268 feet long, 45-foot beam, and drawing 17 feet under maximum load. There are 40 54-cubic-foot and, for alternate use, 40 34-cubic-foot buckets mounted on the endless chain, which runs on a boom capable of digging at a depth of 50 feet. The dredge has a capacity of 1200 cubic yards per hour in sand or mud and somewhat over half that amount in hard clay and bowlders. The ladder, or elevator, dredge is used extensively in removing gold-bearing sand and will be found discussed and illustrated under GOLD MINING.

Suction Dredges are extensively used where the material to be excavated is mud, sand, or other soft matter which can be mixed with water and pumped through pipes. The excavating machinery consists of a suction pipe which can be lowered through a well or over the side or end of the hull, a centrifugal pump for sucking or drawing a stream of water through the suction pipe, and a discharge pipe through which the pump discharges the water thus sucked in. In operation the end of the suction pipe is lowered to the soft bottom and partly buries its end in the material. The pump is then started and sucks a stream of water and mud through the suction pipe and discharges it into the discharge pipe. In most dredges of this type the end of the suction pipe is provided with revolving cutters or with water jets to loosen the material, so that it will be more easily drawn into the suction pipe. The discharge pipe may lead to hoppers in the dredge, or it may be extended to the shore and discharged at some point where land is to be filled in or where the waste material will do no injury. The two suction dredges built during 1900 for removing the 40,000,000 cubic yards of sand and mud in the East Channel improvement of New York harbor are among the most complete suction dredges of the hopper type ever built. These dredges have hulls 300 feet long, with a beam of $52\frac{1}{2}$ feet and a depth of 25 feet. The hoppers on each dredge have a capacity of 2800 cubic yards and occupy a space of 125 feet amidships on each side of the hull. Between the two rows of hoppers is the well for the suction pipe. Water jets are used to loosen the material. The centrifugal pump has a capacity of 75,000 gallons of water per minute. The dredge is provided with its own propelling machinery.

The four types of dredges which have been briefly described are often modified in their construction and arrangement for special uses, and the features of one type are often combined

with the features of another type to form a combination machine. The best descriptions of dredges are to be found in the various engineering society periodicals and the engineering papers of Europe and America. Consult C. Prelini, *Dredges and Dredging* (New York, 1911).

DREDGING, DEEP-SEA. See DEEP-SEA EXPLORATION.

DRED SCOTT CASE. One of the most important cases ever decided by the Supreme Court of the United States. It came up from the lower court on an agreed statement of fact. One Dred Scott, a slave owned by Dr. Emerson, of the regular army, a resident of Missouri, had in 1834 been taken by his owner into Illinois, a Commonwealth where slavery was prohibited, and had later (1836) been taken into what is now Minnesota—a part of the Louisiana Purchase, in which slavery was expressly prohibited by the Missouri Compromise of 1820 (q.v.). While on free territory (1836) Scott had been allowed to marry, his wife being a slave, also owned by Dr. Emerson; and later—in 1838—with his wife and a child born to them on free soil, he was taken back into Missouri. In 1848 he resolved to sue for his freedom, and in this purpose he was gratuitously aided by prominent lawyers of free-soil beliefs. The chief ground of his contention was that, though his residence in territory where slavery was prohibited, he had lost his status as a slave and acquired that of a freeman. The Supreme Court of Missouri, however, held (1852) that, upon being brought back into territory where slavery was legal, the status of slavery reattached to him and that he had no standing before the court. As involving a question under the Federal laws and Constitution, the case was brought in 1854 before the Federal Circuit Court, which held that Scott was a citizen of Missouri and could be a party in a suit before a Federal court, but decided the case against him. The case was then taken on appeal to the Supreme Court of the United States, where the chief legal question was as to the correctness of the lower court's decision that the Federal court might take jurisdiction of a case brought by a person of such a status as was that of Scott. The case was argued at length in 1855 and 1856, and the decision was not finally handed down until March, 1857. The Supreme Court held (Curtis and McLean dissenting) that the Circuit Court had erred in entertaining the suit, because Scott was not a citizen and therefore was not entitled to any standing in the courts; that, at the time of the formation of the Constitution, negroes descended from negro slaves were not, and could not be, citizens in any of the States; and that there was no power in the existing form of government to make citizens of such persons. This point was so decided by a majority of the court. In the course of his decision Judge Taney used the following language: "It is difficult, at this day, to realize the state of public opinion in relation to that unfortunate race which prevailed in the civilized and enlightened portions of the world at the time of the Declaration of Independence and when the Constitution was framed and adopted. But the public history of every European nation displays it in a manner too plain to be mistaken. They had for more than a century before been regarded as beings of an inferior order and altogether unfit to associate with the white race, either in social

or political relations; and so far inferior that they had no rights which the white man was bound to respect, and that the negro might justly and lawfully be reduced to slavery for his benefit. He was bought and sold, and treated as an ordinary article of merchandise and traffic, whenever a profit could be made by it. The opinion was at that time fixed and universal in the civilized portion of the white race." The single sentence, "no rights which the white man was bound to respect," has often been quoted apart from its connection, though it was designed merely as a statement of opinions prevalent when the Constitution was adopted. A dissenting opinion, however, was read by Mr. Justice Curtis, showing the error of Chief Justice Taney's historical argument against the possibility of such persons attaining citizenship, and forcibly contending that, as nothing had been shown except that Scott was a negro and was descended from negroes who had been slaves, his claim to citizenship had not been seriously controverted. Not content with deciding the only question of law involved, the Chief Justice, in an *obiter dictum* which has become historic, went further and undertook the discussion of matters generally considered foreign to the case and not necessarily involved in the decision of the lower court. Taking up the subject, at that time of vital importance, of the power of Congress over the Territories, the majority of the court held that the Missouri Compromise was unconstitutional; that the power of Congress to govern the Territories was subordinate to its obligation to protect private rights in property; that slaves were property and, as such, were protected by the constitutional guarantees; that Congress had no power to prohibit a citizen of any State from carrying into any Territory slaves or any other property; and that Congress had no power to impair the constitutional protection of such property while thus held in a Territory. By this dictum (from which Curtis and McLean wholly, and Catron partially, dissented) one of the extreme doctrines of the proslavery party was affirmed as correct, and even the dogma of "popular sovereignty" was discountenanced. The decision, coming immediately after the inauguration of Buchanan, aroused intense feeling, made still more clear the issues which were to be decided in the impending crisis, and impressed upon the North the seriousness of the task of the party of freedom, when opposed both by the executive and by the judicial departments of the national government. The full text of the decision is in vol. xix of Howard's *United States Reports*. Consult also: Tyler, *Life of R. B. Taney* (Baltimore, revised ed., 1872); G. T. Curtis, *Memoirs and Writings of Benjamin R. Curtis* (Boston, 1880); Corwin, "The Dred Scott Decision in the Light of Contemporary Legal Doctrines," in *American Historical Review*, vol. xvii (1911).

DREIBUND, drī'būnt. See TRIPLE ALLIANCE.

DREISER, drī'sēr, THEODORE (1871-). An American editor and author, born in Terre Haute, Ind., and educated at Indiana University. Taking up newspaper work on the *Chicago Daily Globe* (1892), he was later dramatic editor and traveling correspondent of the *St. Louis Globe-Democrat* (1892-93) and traveling correspondent of the *St. Louis Republic* (1893-94). Subsequently he did special work for a number of magazines, and was editor of *Smith's Magazine*

(1905-06), managing editor of the *Broadway Magazine* (1906-07), and editor in chief of the Butterick publications (1907-10). Besides his special magazine articles, he is author of *Sister Carrie* (1900; 3d ed., 1912); *Jennie Gerhardt* (1911); *The Financier* (1912); *A Traveler at Forty* (1913); *The Titan* (1914).

DREISSENSIA (Neo-Lat., from *Dreyssen*, a Belgian naturalist). A genus of small lamellibranchiate mollusks, allied to the mussels. *Dreissensia polymorpha* is interesting because, having been accidentally introduced from its native home about the Caspian Sea into western Europe, it has fully established itself and has invaded water pipes in many districts of Great Britain, becoming a nuisance. It is capable of living a long time out of water with its valves closed and may have come to Great Britain on timber imported from the Continent.

DRELINCOURT, drā-lān'kōōr', CHARLES (1595-1669). A French Protestant theologian, born in Sedan. In 1620 he went to Paris and was made minister of the church at Charenton. Among the best known of his writings, many of which were popular in English translations, are: *De la persévérance des saints* (1625); *Du jubilé des églises réformées avec le jubilé de l'église romaine* (1627); *Consolations de l'âme fidèle contre les frayeurs de la mort* (1651), to promote the sale of which Defoe wrote the *Apparition of Mrs. Veal*. He wrote a catechism (1642) and many anti-Catholic pamphlets.

DREN'TELN, ALEXANDER ROMANOVITCH (1820-88). A Russian soldier, born in Kiev. He entered the army in 1838, in 1867 became adjutant general, and in 1877, at the outbreak of the Russo-Turkish War, was appointed to the command of the reserves in Rumania. From 1878 to 1880 he was director of the third section of the Imperial Chancellery, in which capacity he controlled that portion of the Russian police which had to do with political offenses. An attempt upon his life was made by a Nihilist in 1879. In 1880 he was appointed a member of the Imperial Council and Governor-General of Odessa, in the latter capacity being transferred to Kiev a year later.

DREP'ANUM. See TRAPANI.

DRESDEN, drēz'den. A town of Kent Co., Ontario, Canada, at the head of navigation on the Sydenham River (Map: Ontario, B 8) and on the Erie and Huron division of the Père Marquette Railroad. It has flour mills, elevators, grist mill, foundry, builders' factory, planing mill, cannery, and creamery. It is situated in a fertile farming district producing, in addition to the staple agricultural products, sugar beets and tobacco. Pop. 1901. 1613; 1911, 1551.

DRESDEN, drēz'den, Ger. pron. drās'den. A city of Germany, capital of the Kingdom of Saxony, situated on both banks of the Elbe, in lat. 51° 3' 3" N. and long. 13° 44' E., by rail 71 miles east-southeast of Leipzig and 111 miles south of Berlin (Map: German Empire, E 3). The Elbe separates the Altstadt and Friedrichstadt and their eight suburbs on the left bank from the Neustadt and Antonstadt with their suburbs on the right bank. The river is crossed by five bridges. The Augustus Bridge, built in the fourteenth century, was replaced in 1727-31 by a structure 1420 feet long, with 16 arches; this was demolished and was replaced in 1908-09 by a wider bridge, known as the Frederick Augustus Bridge. In the Altstadt the streets are mostly narrow; in the Neustadt they are more spacious.

Dresden has numerous squares and parks, both in the old and the new parts. Its largest park, the Grosse Garten, is situated southeast of the Altstadt and contains, besides numerous statues, a museum of antiquities and a zoological and a botanical garden. It was laid out in 1870 and contains 383 acres. The most noteworthy of the squares of the Altstadt are the Altmarkt, the Neumarkt with its Luther Memorial, the Theater-Platz with the statue of King John by Schilling, and the Schloss-Platz. Across the Elbe the principal squares are the Albert, the Kaiser Wilhelm, and the Alaun. Along the left bank of the Elbe lies the Brühl Terrace, the finest promenade of the city. It is about half a mile long, with a beautiful staircase decorated with gilded statuary. The churches of Dresden are numerous but none of them is of great interest. The church of Our Lady in the Neumarkt, dating from the beginning of the eighteenth century, has a lofty lantern (311 feet) and contains a fine baroque altar. Near the Augustus Bridge is the Roman Catholic Court Church (1739-51), in the baroque style. It is surmounted by a tower 280 feet high, and its façade is adorned with 59 statues of saints by Mattioli. The Protestant Sophienkirche, with twin spires, was built in 1351-57, and was restored in 1864-68.

Among the secular buildings the most prominent is the royal palace, built in 1530-35 by Duke George and considerably enlarged and adorned by Augustus the Strong; it was restored and partly rebuilt in 1890-1902. It is partly built in the style of the seventeenth century and has a tower 331 feet high. Its great court contains several noteworthy winding staircase towers. The banquet and throne halls are decorated with mural frescoes by Bendemann. The Zwinger (begun in 1711) is the vestibule of an extensive and magnificent palace begun during the reign of Augustus the Strong by the court architect Poppelmann, and never completed. The Zwinger comprises seven pavilions connected by a gallery, with an oblong court in the centre. It is built in the baroque and rococo styles. Its northeast wing forms the Museum, a very fine building in the Renaissance (1846-55). It is profusely decorated with sculptures, including statues of Michelangelo, Giotto, Holbein, Dürer, and Goethe. Among other public buildings are the Prinzen-Palais, erected in 1715, the Brühl Palace, and the Court Theatre, a beautiful Renaissance edifice completed in 1878. The new post office, the Academy of Medicine and Surgery, the Rathaus, and the courthouses are also noteworthy. Among the public buildings of the Neustadt, the most interesting is the Japanese Palace, dating from 1715, and now containing the Royal Library.

Among the educational institutions of Dresden are the Royal Technical High School, with several faculties and over 1500 students in 1913, a number of gymnasia and realschulen, and several art and denominational schools. The Royal Music School is one of the most celebrated institutions of its kind. Dresden has three municipal theatres, of which the famous Court Theatre is devoted to opera and important dramas and is one of the leading theatres in the world. In art collections and libraries Dresden ranks high. As early as the sixteenth century the Saxon princes began to accumulate works of art and laid the foundations of the splendid galleries and museums for which Dresden is

famous. The Royal Library was founded by the Elector Augustus in the sixteenth century. It contains about 570,000 volumes, a large number of manuscripts and maps, and a collection of portraits. The Museum Johanneum possesses a rare collection of Chinese, Japanese, Indian, Sèvres, and Dresden porcelain, numbering about 15,000 pieces.

The Dresden Picture Gallery, for which the city is best known, is located in the Museum of the Zwinger, and contains upward of 2500 canvases. The collection is especially rich in Italian and Dutch works. Among the numerous Italian masters represented are, first of all, Raphael with his most celebrated picture, "The Sistine Madonna"; Andrea del Sarto; Correggio ("Holy Night"); Titian ("The Tribute Money"); Palma Vecchio ("Venus and the Graces"); Paolo Veronese, Tintoretto, Caravaggio ("The Card Sharper"), and Ribera are also to be seen here to advantage. Of the Spanish school Velasquez and Murillo are represented by one fine picture each. Masterpieces of the Flemish school are especially numerous, including the "Boar Hunt" and other famous canvases by Rubens, admirable portraits by Van Dyck, and a number of pictures by Jordaens and Teniers the Elder. Among the Dutch masters are Rembrandt ("Portrait of Himself and his Wife sitting on his Knee" and "Manoah's Sacrifice"), Frans Hals, G. Dou, Adriaen van Ostade, Ruysdael, Paul Potter, Van der Meer, Terburg, and Metz. The French schools of the seventeenth and eighteenth centuries are represented by landscapes of Claude Lorrain and examples of Poussin and Watteau. Of the German school, Holbein and Dürer are the conspicuous figures. There are masterpieces by modern painters, including Munkácsy, Fritz von Uhde, Böcklin, and Delaroche. Besides the picture gallery the museum contains over 350,000 woodcuts and copper engravings. Among other collections in Dresden may be mentioned that of precious stones, jewels, etc., in the famous Green Vault of the royal palace. There is also the collection of ancient and modern arms, implements, and costumes in the Museum Johanneum, one of the completest historical museums in Germany.

Dresden is administered by a chief burgo-master, 2 burgomasters, 33 aldermen, 17 assessors and referendaries, and a council of 72 members. The municipality owns and manages its water works, gas plant, and an electric plant, as well as the abattoirs. The cleaning of the streets is done entirely by the city, which is one of the cleanest in Germany. The Dresden Bank is a very large and important institution.

The manufacturing industries and commerce of the city are of considerable importance. Noteworthy products are machinery, pianos, gold and silver articles, paper, and porcelain. The publication of books and the production of art objects of various kinds are very extensive. Dresden is the seat of consular representatives from numerous countries, including the United States. The commerce is considerable, mostly by rail. The completion of its fine harbor will undoubtedly give a stimulus to water transportation. In 1834 the population was 73,614; in 1852, 104,500; in 1880, 220,818; in 1890, after the annexation of Strehlen and Striesen, it had increased to 289,841. In 1895, after further annexation of suburbs, the population was 354,285; in 1900 the total reached 396,146, and, in 1910, 548,308. Two-thirds of the inhabitants

live on the left bank (Altstadt) of the Elbe. The great majority are Lutherans, though the royal house is Roman Catholic. Dresden is the royal residence, the seat of government for Saxony, and the headquarters of the Twelfth Army Corps. The climate of Dresden is marked by frequent and sudden changes. The suburbs along the picturesque Elbe as far as Pillnitz are very attractive, with their castles, beautiful villas, and interesting associations in connection with the lives of famous Germans.

History. Dresden is of Slavic origin. It was first called a city in 1216. At the end of the thirteenth century it became the residence of the margraves of Meissen, but did not begin to grow before the end of the fifteenth century, when it passed to the Albertine line. Its fortifications were begun in the sixteenth century. Many considerable and attractive improvements were made by John George II, including the Grosse Garten, and under the rule of Augustus II and III (1694-1763) Dresden became one of the finest cities of Europe. The old part was ruined by the fire of 1685 and was rebuilt as the Neustadt by Augustus I in 1732. The Seven Years' War put an end to the growth of the city, and the bombardment of 1760 by the Prussians destroyed many of its buildings. During the Napoleonic wars Dresden suffered considerably. In 1813 it was converted by Napoleon into a great arsenal, and here he won his last victory on German soil. (See DRESDEN, BATTLE OF.) In 1817 the fortifications were demolished to give way to promenades. With the opening of the Elbe to navigation, and the construction of railways, the city began to grow in economic importance, and its progress was only slightly retarded by the political upheavals of 1848-49. In 1866 Dresden was taken by the Prussians, who held it until the end of 1867. Consult: Lindau, *Geschichte der königlichen Haupt- und Residenzstadt Dresden* (Dresden, 1884-85); Gsell-Fels, *Dresden und Umgebung* (Munich, 1896); Sendig, *Dresden, eine Fremdenstadt* (Dresden, 1898); Schumann, *Führer durch die Architektur Dresdens* (ib., 1899); Gurlitt, *Die Kunstdenkmäler Dresdens* (ib., 1900); *Statistisches Jahrbuch für die Stadt Dresden* (ib., 1899 et seq.).

DRESDEN, BATTLE OF. A battle fought, Aug. 26-27, 1813, between the French, under Napoleon, and an allied army of Austrians, Russians, and Prussians, under the command of Prince Schwarzenberg. On August 21 the allies had begun their march from Bohemia, and on the 25th they appeared, 150,000 strong, before Dresden, which was defended by Saint-Cyr, with 20,000 French troops. Napoleon had left the city on the 17th to go to the support of Ney, who was operating against the Army of Silesia under Blücher. On receiving news that the allies were preparing to attack Dresden, he immediately returned by forced marches, but on the 25th he was still 15 miles from the capital, and had it not been for a fatal delay on the part of Prince Schwarzenberg, the city might have been taken before the Emperor's arrival. As it was, the assault was not delivered until seven o'clock on the morning of the 26th. The French were intrenched in the Altstadt, on the southern bank of the Elbe, and had command of the bridge across the river. The line of the allies extended in a huge crescent to the east and south of the city, with the Russians on the right wing, the Prussians in

the centre, and the Austrians on the left. In the first attack the allies were successful along the entire line, in spite of the desperate resistance of the French. The Russians stormed one of the fortifications to the east of the city, the Prussians gained possession of the greater part of the Royal Park to the south, while the Austrians carried the suburbs to the southwest. It seemed, early in the morning of the 26th, that Saint-Cyr would be compelled to capitulate. At noon, however, the Russian and Prussian advance was checked by order of the commander in chief, in expectation, probably, of a reinforcement of 50,000 men under Klenau, and the attack was not resumed until four o'clock in the afternoon. About noon French troops began pouring into the city from across the Elbe. Napoleon had arrived; and when the allies resumed the assault, the French had 100,000 men to oppose them. The effect was felt at once. The Russians on the right were driven from their positions, and in the centre the Prussians lost part of the ground they had gained in the morning. The Austrians on the left were also checked. Night and rain brought a stop to the fighting. Napoleon meanwhile had determined to deliver an attack on both wings of the allied army simultaneously and then, by converging on the Prussian position, to crush the enemy's centre. The battle was resumed at six o'clock in the morning. On the right wing of the allies the divisions of Ney and Mortier drove the Russians from the heights to the south of the city. The victory, however, was gained on the French right. There, while Victor was assaulting the Austrians, Murat, with 20,000 cavalry, swept around their left flank and took them in the rear, crushing out all resistance and taking more than 13,000 prisoners. The Prussians in the centre were prevented from going to the support of either wing by a furious cannonade and repeated charges of the Old and the New Guard. At four o'clock in the afternoon the allies began the retreat into Bohemia. The loss of the allies in killed and wounded was about 15,000 or 18,000, and more than 20,000 prisoners fell into the hands of the French. Their own losses were about 10,000 in killed and wounded.

DRESS (Lat. *directus*, straight, through, Fr. *dresser*, to set up or straighten). The clothes worn by men, women, and children. As considered from the point of view of style, the subject is treated under **COSTUME** and **FASHION**. It is almost a truism to say that the progress of civilization is marked by the progress of clothes, and that, other things being equal, the best-clothed nations are the nations most highly developed. When the energy of the human body is wasted in combat or amid cold or heat or moisture or dirt, less is left for the accomplishment of useful tasks, of creative mental and physical labor. From the economical point of view, as well as from the point of view of comfort, clothing and cleanliness pay.

Modern dress is determined mainly by four considerations—climate, hygiene, decency, and use—although fashion or convention may override all of these. Cold in the winter, heat, dust, and insects in the summer, are important factors in regulating the amount and kind of dress worn. The use of washable underclothing and the frequent bathing of the body are characteristic of advanced civilization which demands increasing attention to the hygiene of clothing,

its character and texture, as well as to the hygiene of the body. The Greeks and Romans had already developed the use of an inner garment (Greek *χιτών*, Roman *tunica*) in addition to the outer garment (Greek *ιμάριον*, Roman *toga*), while about the time of Augustus the Romans had also begun to wear an undershirt (*tunica interior* or *intima*). Sense of decency or conventional modesty is an important consideration in the determinations of dress at any period, but it is impossible to decide to what extent one is controlled by the other. Finally, the shape or cut of clothes may be regulated by their value in use. Thus, the women who work in the field, as in Switzerland, or in the mines, as in Belgium, wear trousers instead of the conventional skirts, which not only hamper the movement of the body, but may also be unhygienic. So too the modern development of gymnastic and athletic sports has led to specialized forms of dress both for men and women. See **TEXTILES**. For bibliography, see **COSTUME**; **FASHION**.

DRESSER, HENRY EELES (1838–). An English ornithologist. He was born at Thirsk, Yorkshire, and, after studying in England, Germany, and Sweden, devoted himself to commercial pursuits, giving considerable time, however, to investigations in European ornithology, on which subject he is considered an authority. He wrote: *A History of the Birds of Europe* (8 vols., with colored plates, 1871–81); *A Monograph of the Meropidae, or Family of the Bee Eaters* (1884–86); *A Monograph of the Coraciidae, or the Family of the Rollers* (1893); *Manual of Palearctic Birds* (1902–03).

DRESSINGS. In architecture, a term loosely used to signify the more finely finished parts of the exterior as distinguished from the plainer work of the walls; especially the decorative parts around windows and doors, and bands, moldings, copings, etc.

DRESS REFORM. Dress reform, in the narrow sense in which it is customary to use the term, signifies a more or less definite and concerted movement against unhygienic clothing for women which began about the middle of the nineteenth century.

In the United States the earliest crusader against long skirts, high heels, a multiplicity of bands, restricted breathing capacity, and other unhygienic forms of clothing, was Amelia Bloomer. In 1851 Mrs. Bloomer, as editor of the *Lily*, a paper advocating equal-suffrage rights for men and women, gave some space to the discussion of a comfortable and sensible dress for women. In her case this dress took the form of full Syrian or Turkish trousers extending to the ankle in summer, and in winter tucked into high boot tops, worn with a scant skirt coming just below the knees. The credit of originating this costume, although it has always been known by her name, Mrs. Bloomer in her writings expressly gives to Mrs. Elizabeth Smith Miller, from whom she says she copied it, as did Mrs. Elizabeth Cady Stanton. Mrs. Lucy Stone (Blackwell), another of the pioneer American women suffragists, also adopted it for a time. But all of these ladies eventually returned to a dress more closely resembling the generally accepted one of their day.

As early as 1857 a National Dress Association was engaged in trying to spread hygienic ideals of dress among the women of the United States,

but their efforts seem to have been abortive at that time.

In England the Rational Dress Movement, as it was called, began in the seventies. It grew about equally from two roots—the Pre-Raphaelite æstheticism, which flourished at that time, and a zeal for woven woolen clothing, which, sweeping over Germany, spread to England. The Pre-Raphaelites advocated, as an artistic need, a return to the simple lines and the color combinations which they declared had not been found in English costumes since the middle of the fourteenth century. The “antique” waist—untrammelled and large—was taught by them to be more beautiful as well as more healthful than the tapering, hourglass waist. In spite of the clever ridicule spent upon them as apostles of a “greenery gallery” cult, they really accomplished something for the cause of dress reform. The “woolen” crusade of the same period, basing its arguments upon pathological rather than æsthetic grounds, also bore excellent fruit in warmer, more closely fitting, less cumbersome underclothing.

In 1874 a second National Dress Association was formed in Boston. Lectures were given by prominent physicians in which were attacked the chief evils of women's dress—viz., the corset, distorting the internal organs and interfering with breathing; the carrying of a weight of cloth upon the hips, resulting in further abdominal displacements; the long skirt, impeding locomotion and harboring disease germs; the capricious and uneven nature of the protection against cold; the high heels and pointed toes of shoes, causing unhealthiness of the entire body as well as local troubles; and the face veil, that prolific source of ocular troubles.

Systems of rational dress have been devised as a result of this movement. In the United States Mrs. Anna Jenness-Miller became the most widely known exponent of a system combining a due regard for hygiene with some regard for beauty and for ancient prejudices. In England Lady Harberton, president of the Rational Dress Association, became the recognized leader of the movement. Her system differs greatly from that of Mrs. Jenness-Miller, for she advocates a modification of the Turkish trouser costume, clothing her servants in it. In England there are also a National Health Dress Association and a National Funeral and Mourning Reform Association.

At the World's Fair in Chicago in 1892 a Dress Reform Congress was held, and new life was infused into the cause. So many cities organized Rainy-Day Clubs, with members pledged to wear short skirts in sloppy weather, that the rainy-day skirt is now as familiar an object of the fashion plate and of commerce as the pelisse and the dolman once were.

In Germany the first definite effort of modern times against unhygienic clothing for women was made under the auspices of the Crown Princess of Saxony in 1873. At her suggestion Dr. Max V. Pettenkofer, professor of hygiene at the University of Munich, delivered a course of lectures on the subject which aroused some public interest. Almost at the same time Dr. Jaeger, of Stuttgart, inaugurated his crusade against all forms of clothing not woolen. The chief articles in his creed were the necessity for warmth about the middle of the body and the prevention of accumulation of fat and water.

Wool, on account of its heating and absorbing qualities, he held to conduce towards this end.

There has been no widespread movement elsewhere on the Continent in favor of a more rational style of dress for women. There has been practically no legislation anywhere on the subject. A minister of education in Russia, in the last decade of the nineteenth century, attempted to prohibit the wearing of corsets by girl students under a certain age, but was unable to accomplish this reform. See DRESS; COSTUME; FASHION.

The general participation of women in outdoor sports has probably done as much for the cause of dress reform as the conventions and agitation of the past—unless, indeed, all this has made the participation possible. Athletics, however, demanding short skirts, ample breathing space, light-weight but warm clothing, and the possibility of unhampered movements, and making conventional the attire which permits all these, is undoubtedly the strongest ally which dress reform has ever had. Consult: Woolson, *Dress Reform* (Boston, 1874); Bloomer, *The Life and Writings of Amelia Bloomer* (ib., 1895); Godwin, *Dress and its Relation to Health and Climate* (London, 1884); Haweis, *The Art of Dress* (ib., 1881).

DRESS SHIP. A nautical term for ornamenting a ship with flags. It is usually done on national holidays, on the occasion of some particular fête or celebration, or in honor of some distinguished visitor, or as a mark of courtesy towards foreign nations when their own ships are dressed. In its simplest form it consists in having the national colors at the mastheads and at the peak (head of the spanker gaff) or color staff, and hoisting the jack at its own staff in the bow. To full-dress ships additional flags are hoisted. These consist of the flags of the signal code. (See SIGNALS, MARINE.) In the case of naval vessels the flags of the navy signal code and of the international signal code are both used. The ordinary plan is to have these flags arranged in a line from the water forward (a few are on a weighted line hanging underneath the flying jib boom) up along the line of the stays, then between the mastheads to the peak of the gaff, and thence over the stern. This is called dressing ship *rainbow fashion*. In addition the national colors are hoisted at the mastheads and aft, and jack forward, as before. Should the dressing be a courtesy to a foreign government, the colors of that nation are hoisted at the mainmast head. Vessels having but one mast usually bring the flags past the smoke pipes aft to the stern in two lines. No national colors are used in dressing ship except at the mainmast head, as already mentioned, as it would be considered discourteous to exhibit one and not another, or to place one in an inferior position to that of another, and all could not be given positions of honor. Merchant ships frequently, and men-of-war occasionally, dress ship by arranging the lines of flags on each mast from the masthead to the water, following the extremities of the yardarms.

DREUX, drê. The capital of an arrondissement in the Department of Eure-et-Loir, France, on the Blaise, 51 miles west of Paris (Map: France, N., G 4). The principal buildings are the church of Saint-Pierre, a fine unfinished Gothic structure of the period from the thirteenth to the fifteenth century; a splendid town

hall, dating from the sixteenth century, containing a notable organ case; the Doric mortuary Chapelle Saint-Louis of the Orléans family, with numerous pieces of sculpture, and beautiful stained-glass windows; and the ruins of the ancient castle of the counts de Dreux. Dreux has extensive foundries and nurseries, with manufactures of coarse cloth, serge, leather, and glass, with a trade in sheep and cattle. Pop., 1901, 9697; 1911, 10,692. Dreux was an important town of the ancient Gauls and was called Durocassis or Drocæ by the Romans. It gave its name to a famous line of counts which became extinct in 1378. It was the scene, on Dec. 19, 1562, of the first great battle in the wars of France, when the Catholics, under the Duc de Guise defeated the Huguenots and took their leader, the Prince of Condé, prisoner. In 1870 it was taken by the Germans.

DREVET, dré-vá'. A family of French engravers.—**PIERRE** (1663-1738) was born at Loire, near Lyons, studied at Lyons, and then went to Paris, where he was a pupil of Gerard Audran and Hyacinthe Rigaud. In 1696 he was made engraver to the King, and in 1707 became an Academician. Drevet's best work was done after portraits by Rigaud, and his masterpiece is "Louis XIV standing before the Throne" (1712). In his delicate gradation of tones and management of detail he is hardly surpassed by any engraver of his day. He left 125 plates. Among his pupils was his son **PIERRE IMBERT** (1697-1739), who, when 26 years old, engraved the portrait of Bossuet after Rigaud, which in every sense is a masterpiece. He surpassed his father in grace and precision and in his use of light and shade as an interpretation of color, but they did many plates together, and it is often difficult to isolate the work of one. Pierre Imbert was also engraver to the King. Among his plates are some beautiful specimens after Coypel and Louis de Boullogne and fine portraits of Adrienne Lecouvreur and Samuel Bernard.—**CLAUDE** (1697-1781) was a nephew and pupil of Pierre. He was not the equal of his uncle or his cousin and has left only five plates representing religious subjects and nine portraits after Rigaud. Consult *Les Drevets* (Paris, 1876).

DREW, DANIEL (1797-1879). An American capitalist. He was born in Carmel, N. Y., where he began life as a drover and dealer in cattle. In 1834 he bought an interest in a steamboat which was run between New York and Peekskill, in competition with the line established by Cornelius Vanderbilt. The service was improved by the addition of new boats, and in 1840 Drew became the controlling proprietor of the newly established People's Line. In 1847 he established the Stonington Line and in 1850 made his first venture in railroading by joining with Cornelius Vanderbilt in the purchase of the railroad between Stonington and Boston. He established the banking firm of Drew, Robinson & Co., which became one of the principal traders in railroad stocks in the country. Drew became a director and large stockholder in the Erie Railroad and at one time was said to be worth \$15,000,000. Later, principally through the failure of Kenyon, Cox & Co., in which firm he was a partner, he suffered severe losses, which drove him ultimately into bankruptcy. In his prosperous days he had been a generous supporter of the Methodist Episcopal church, erecting several church edifices, and founding

the Drew Ladies' Seminary at Carmel, N. Y., and in 1866 the Drew Theological Seminary at Madison, N. J. Consult *The Book of Daniel Drew* by Bouck White (New York, 1910).

DREW, JOHN (1825-62). A popular Irish-American comedian. He was born in Dublin and made his first appearance at the Bowery Theatre, New York City, in 1846. During the next 10 years he acted in the principal American cities and engaged in theatrical management in Philadelphia, where, after visits to England in 1855 and Australia in 1859, he died. Consult Moses, *Famous Actor-Families in America* (New York, 1906).

DREW, JOHN (1853-). An American comedian, son of John Drew and Louisa Lane Drew. His theatrical career began under his mother's management in Philadelphia in 1873. In 1879, with Edwin Booth, Fanny Davenport, and other well-known stars, he became leading man in Daly's company, which he had first joined four years before. He figured with marked success in *jeune premier* rôles, in the revival of the classic comedies, notably as Petruchio in *The Taming of the Shrew*, and as Charles Surface in *The School for Scandal*, and also in Mr. Daly's new productions. After 1892 he appeared as a star, among his plays being *The Masked Ball*, *The Butterflies*, *A Marriage of Convenience*, *One Summer's Day*, *The Liars*, *Richard Carvel*, *His House in Order*, *Inconstant George*, *Smith*, *The Perplexed Husband*; and *Much Ado About Nothing*, *The Tyranny of Tears*, and *The Will*—the last three in 1913. He finds his best rôles in bantering, semi-ironical society characters. Consult: Strang, *Famous Actors of the Day in America* (Boston, 1900); Moses, *Famous Actor-Families in America* (New York, 1906); Winter, *Wallet of Time* (2 vols., New York, 1913).

DREW, LOUISA LANE (1820-97). An American actress. She was the wife of the elder John Drew and, after him, managed the Arch Street Theatre, Philadelphia, for many years. She was born in London, but came to this country and made her début in Philadelphia when about eight years old. A half-dozen years later she was playing Julia in *The Hunchback* and Lady Teazle in *The School for Scandal*. During her early career she appeared with Forrest and many of the greatest actors of the period. Her own most famous rôle was Mrs. Malaprop in *The Rivals*, which she performed with the utmost apparent simplicity. Mr. Drew, to whom she was married, in 1850, was her third husband. Her sons, John and Sidney, and her daughter, Georgie Drew (Barrymore), all became actors. Consult Moses, *Famous Actor-Families in America* (New York, 1906).

DREW, SAMUEL (1765-1833). An English Wesleyan Methodist author, born near St. Austell, England. Until 1809 he was a shoemaker. In 1785 he joined the Methodists under the preaching of Adam Clarke. Having begun literary work when but a lad, he devoted his entire time to it after giving up his trade, and, besides editing the *Imperial Magazine*, from 1819 until his death, he published: *A Treatise on the Existence and Attributes of God* (2 vols., 1820); *Remarks upon the "Age of Reason"* by Thomas Paine (1799 and several subsequent editions); *An Essay upon the Immateriality and Immortality of the Soul* (1802); *An Essay on the Resurrection of the Body* (1809); *The Life of Rev. Thomas Coke* (1816); *The History of*

Count Cournailles (2 vols., 1820; 1824). Consult *The Life, Character, and Literary Labors of Samuel Drew, A.M.*, by his eldest son (London, 1834; 2d ed., 1835).

DREWRY'S BLUFF, BATTLE OF. See BER-MUDA HUNDRED.

DREWS, ARTHUR (1865–). A German writer on philosophy, born in Uetersen, Holstein, and educated at Munich, Berlin, Heidelberg, and Halle (Ph.D., 1889). In 1898 he went to Karlsruhe as privatdocent of philosophy, and in 1908 he became professor extraordinary. He edited *Hegels Religionsphilosophie* (1905) and criticized Kant, Von Hartmann, and Nietzsche in such volumes as *Kants Naturphilosophie als Grundlage seines Systems* (1894), *E. von Hartmanns philosophisches System in Grundriss* (2d ed., 1905), *Nietzsches Philosophie* (1904), and *Die Lebenswerk Eduard von Hartmanns* (1907). *Plotin und die Untergang der antiken Weltanschauung* (1907) is a valuable historical study; and two of three parts planned of a history of nineteenth-century philosophy appeared in 1912 and 1913. He also wrote: *Die Lehre von Raum und Zeit in nachkantischen Philosophie* (1889); *Das Ich als Grundproblem der Metaphysik* (1897); and his most distinctive books, *Die Religion als Selbstbewusstsein Gottes* (1906), *Der Monismus* (1908), and *Geschichte des Monismus im Altertum* (1913). He is best known, however, especially in America and England, for *Die Christusmythe* (1910; English by Burns, 1911, and part ii, by McCabe, 1912) and *Die Petruslegende* (1910), attacking the historicity of the New Testament narrative.

DREW THEOLOGICAL SEMINARY. An educational institution for the training of Methodist Episcopal ministers. The seminary was founded at Madison, N. J., in 1866, and was named in honor of Daniel Drew, who donated grounds and buildings to the value of about \$275,000. The course of study extends through three years and is intended not only to give a thorough professional training, but to afford opportunity for a broad culture through the study of the humanities. The seminary degree B.D. is given only to graduates holding a prior academic degree. Advanced courses leading to the degree of D.Th. are offered. No tuition fees are charged. The seminary buildings include Mead Hall, Asbury Hall, Embury Hall, the Hoyt-Bowne Hall, the Administration Building and Chapel, the J. B. Cornell Library, the Bowne Gymnasium, and the Samuel W. Bowne Hall. The total value of the grounds and buildings is approximately \$700,000, while the endowment funds aggregate about \$1,000,000. The library is especially valuable, containing 125,000 volumes and 110,000 pamphlets. The enrollment of students in 1914 approximated 200. The president in 1914 was Ezra S. Tipple, D.D.

DREXEL, ANTHONY JOSEPH (1826–93). An American banker and philanthropist, born in Philadelphia. When 12 years old he entered the banking house of Drexel & Co., established in 1838 by his father, Francis Martin Drexel, and at the age of 20 he was admitted to partnership in this firm with his father and elder brother, Francis A. Drexel. In 1885 he became the nominal head of the banking system which included Drexel, Morgan & Co., of New York, and Drexel, Harjes & Co., of Paris. In 1864 Drexel, with George W. Childs, bought the Philadelphia *Public Ledger*. The most notable of his many large gifts was the total of more

than \$2,000,000 given to the Drexel Institute of Art in West Philadelphia. His will disposed of a fortune of about \$30,000,000.

DREXEL INSTITUTE OF ART, SCIENCE, AND INDUSTRY. An educational institution founded in 1891 at Philadelphia, Pa., by Anthony J. Drexel. The object of the Institute is to train men for the industrial demand for engineers; women to practice, superintend, and teach the industries known as domestic science and arts; and both men and women for positions in secretarial work. All the work of the Institute is thus comprised in three schools: the Engineering School, the School of Domestic Science and Arts, and the Secretarial School, special courses being offered in chemistry, architecture, and English. Extension courses are also offered, especially in the School of Domestic Science and Arts, and the evening courses in all three schools constitute one of the most valuable activities of the Institute. The courses of study are open equally to men and women; in 1914 the trustees had applied for the right to grant degrees; the requirement for admission is graduation from high school, or 14½ Carnegie units; and the tuition fees are very moderate, owing to the endowment fund established by Mr. Drexel. The main building, given by Mr. Drexel, is an imposing structure in the style of the classic Renaissance; East Hall, a finely appointed building, in the modern French Renaissance style, contains the notable collection of paintings bequeathed by John D. Lankenau. The Museum embraces specimens in every department of industrial art. In it are many examples of the decorative arts of Egypt, India, China, and Japan, and there is also an important collection of European and Oriental textiles. The Drexel Institute carries on an important educational work through the means of free public lectures and concerts. The number of students in attendance in 1912–13 was 2900 in all departments. The library, containing over 40,000 volumes, is especially well provided with works on art, science, and technology. The president in 1914 was Hollis Godfrey, Sc.D., F.R.G.S.

DREYER, JOHN LOUIS EMIL (1852–). An Irish astronomer, born in Copenhagen, the son of a British army officer. He was educated at the University of Copenhagen, was assistant astronomer at the Earl of Rosse's observatory (1874–78) and assistant at the Dublin University observatory (1878–82), and in 1882 became director of Armagh Observatory. He published: *The Second Armagh Catalogue of 3300 Stars* (1886); *New General Catalogue of Nebulae and Clusters of Stars* (1888; with supplements, 1895; 1908); *Tycho Brahe* (1890); *History of the Planetary Systems from Thales to Kepler* (1906); an edition (1912) of Herschel's *Scientific Papers* for the Royal Society and the Royal Astronomical Society.

DREYFUS, dra'fus', ALFRED (1859–). A French artillery officer. He was born in Mülhausen, Upper Alsace, of Jewish parentage, entered the Ecole Polytechnique in 1878, and later attended the Ecole d'Application (School of Applied Gunnery). He was appointed captain in the Twenty-first Regiment of artillery in 1889 and two years later entered the Ecole de Guerre, where he ranked among the leading 10 of his class. Within a year after leaving this institution he received an appointment on the general staff. In 1894 Dreyfus was arrested

on a charge of having sold military secrets to a foreign power. Dreyfus was isolated in prison and treated with great harshness. When he was tried, although he was allowed counsel, the court was a secret one, and he was sentenced to military degradation and solitary confinement on the Île du Diable, off the coast of French Guiana. On Jan. 4, 1895, he was conducted by a military escort to the courtyard of the Ecole Militaire in Paris, and, in the presence of a great assembly of spectators, the stripes were torn from his uniform and his sword was broken. He was then transported to the Île du Diable, and treated with severity, on one occasion being chained to his pallet for two months. He persistently denied his guilt, and this fact, together with the secrecy of the proceedings and the bitterness of the anti-Semitic agitation, led to a growing conviction in the minds of many that the real culprit had been shielded, and that it had been found convenient to put Dreyfus forward as a scapegoat.

The evidence used against Dreyfus was a memorandum, or *bordereau*, apparently in the captain's handwriting. But in May, 1896, another paper was brought to the War Office and fell into the hands of Commandant Picquart. It bore the signature of Major Esterházy, an officer of doubtful character, and the handwriting corresponded exactly with that of the Dreyfus *bordereau*, while that of Dreyfus did not. Then began a remarkable series of attempts to bring to light and to suppress the truth. The most prominent defender of Dreyfus was the novelist Emile Zola. A large part of the Liberal press also sided with the accused captain, and during the later phases of the affair his cause was adopted by the Socialists as a party issue for the time. Arrayed against him were the anti-Semitic elements of France and the powerful Nationalist influence, the latter consisting of all those who regarded the condemnation of Dreyfus as necessary for the vindication of the honor of the army, always dear to the hearts of Frenchmen. The War Office met the attacks of the friends of Dreyfus simply by asserting that the proceedings against him had been regular in every respect. There was a fixed purpose to prevent any discussion of the nature of the evidence or the facts of the case. Commandant Picquart, who showed an honest desire to bring out the truth, was made a lieutenant colonel and sent away on special service. Attempts were then made to compromise him by means of false dispatches, and he was finally removed from the active list of the army. In 1898 a new declaration was made in the Chamber of Deputies by M. Cavaignac, Minister of War. He positively asserted that Dreyfus had been justly found guilty and referred to certain documents not hitherto mentioned in the case. Colonel Picquart challenged these proofs and declared that, of the three documents upon which M. Cavaignac based his belief in the guilt of Dreyfus, two were irrelevant, and the third, the only one in which Dreyfus's name occurred, was a forgery. Six weeks later Colonel Henry, who had been connected with the intelligence department of the War Office, confessed to having committed this forgery and committed suicide. This led to a general readjustment in the organization of the general staff, and several officers were removed from the active list, but still the War Office proclaimed its belief in the guilt of Captain Dreyfus. The

Court of Cassation, however, the highest tribunal in France, had taken up the matter of revision and after several months' deliberation ordered a retrial by a court-martial. The court-martial sat at Rennes and rendered a decision that Dreyfus was guilty, but with extenuating circumstances. He was sentenced to imprisonment for 10 years, from which the period of his previous confinement was to be deducted. The members of the court-martial then united in a recommendation of mercy, and in 1899 the prisoner was pardoned by President Loubet.

The question was reopened in 1903, when a parliamentary committee of revision decided that certain "new" facts had been adduced, justifying their submission to the Court of Cassation. On the grounds that the document by which the conviction of Dreyfus in the Rennes court-martial was chiefly determined had been proven to be a forgery, and that the court-martial had failed to hear essential testimony favorable to the accused, the Court of Cassation annulled the sentence of the Rennes court-martial without ordering a new trial. Captain Dreyfus was thereby declared innocent and ipso facto restored to his old rank in the army. On the day following the announcement of the court's decision, the Chambers passed a bill raising Captain Dreyfus to the rank of major. In 1908 Dreyfus was shot at in Paris by a reactionary journalist, but escaped without serious injury. The Dreyfus affair created much excitement at the time, and the final outcome was hailed as a great triumph over militarism in France.

Bibliography. Captain Dreyfus's own story: *Five Years of my Life* (New York, 1901); Reinach, *Histoire de l'affaire Dreyfus* (4 vols., Paris, 1901-04); Desachy, *Bibliographie de l'affaire Dreyfus* (ib., 1905).

DREYSCHÖCK, drī'shök, ALEXANDER (1818-69). A Bohemian pianist, born at Zach, Bohemia. As a pupil of Tomaschek, at Prague, he developed a technique marvelous for his time. "The man has no left hand. He has two right hands," was J. B. Cramer's exclamation after hearing him play. In 1828 he began concert touring and continued to do so successfully for 20 years. In 1862 he was appointed a professor in the Conservatory of Music at St. Petersburg, where he remained until 1868, when failing health compelled him to go to Italy. His compositions are of the salon order and unimportant. He died in Venice.

DREYSE, drī'ze, JOHANN NIKOLAUS VON (1787-1867). A German inventor. He was born in Saxony, served an apprenticeship with his father, a locksmith, and then worked for a time in a musket factory in Paris. In 1814 he founded an ironware factory in Sömmerda and became interested in the manufacture of firearms. In 1827, he invented a muzzle-loading, and in 1836 a breech-loading, needle gun, the adoption of which by the Prussian army four years later led to his founding an extensive gun and ammunition factory. He was ennobled in 1864.

DRIESCH, drēsh, HANS (1867-). A German biologist, born in Kreuznach, Rhenish Prussia. He was educated at the Hamburg Johanneum and at the universities of Freiberg, Munich, and Jena. He traveled in Ceylon, Burma, India, and Java in 1889 and in 1893, and in 1891-1900 worked at the Naples Stazione Zoologica. Settling at Heidelberg in 1900, he became privat-

docent (1909) and professor extraordinary (1911) of philosophy. Gifford lecturer at Aberdeen in 1907-08, he received the honorary degree of LL.D. from that university in 1910. He was one of the founders of "vitalistic" biology. Besides biology, and particularly experimental morphology of animals (parthenogenesis, regeneration of lost parts), he devoted himself to natural philosophy and logic. He contributed to the *Archiv für Entwicklungs-Mechanik*, the *Zeitschrift für wissenschaftlichen Zoologie*, etc., and published: *Die mathematisch-mechanische Betrachtung morphologischer Probleme der Biologie* (1891); *Die Biologie als selbständige Grundwissenschaft* (1893; 2d ed., 1911); *Analytische Theorie der organischen Entwicklung* (1894); *Die Localisation morphogenetischer Vorgänge* (1899); *Die organischen Regulationen* (1901); *Die "Scele" als elementarer Naturfactor* (1903); *Naturbegriffe und Natururteile* (1904); *Vitalismus als Geschichte und als Lehre* (1905); *The Science and Philosophy of the Organism* (1908-09); *Ordnungslehre* (1912); *Logik als Aufgabe* (1913); *The Problem of Individuality* (1914).

DRIFT (from AS. *drifan*, Icel. *drífa*, Goth. *drieban*, OHG. *triban*, Ger. *treiben*, to drive), or **GLACIAL DRIFT**. A name applied to glacial deposits in general that were formed during the Pleistocene period. The great ice sheets which at that time covered the northern parts of North America, Europe, and Asia were efficient agents of erosion and transportation. Vast masses of loose materials, including earth, sand, and stones, were conveyed on their surface or in their lower portions, and on the retreat of the ice the materials were left behind as a compact, structureless deposit of variable thickness. The drift is variously called till, bowlder clay, ground moraine, and older diluvium. It quite frequently occurs in ridges or hillocks (drumlins, kames, and eskers) in the formation of which the action of streams that resulted from the melting of the ice is apparent. The stones in drift have a characteristic appearance and surface. They are usually of oblong shape, highly polished, and have rounded edges. When the rock is fine-grained, numerous striæ may be seen running parallel to the longer axis of the fragment. Sometimes the stones have been transported long distances. The peculiar syenite known as laurvikite, which occurs in the vicinity of Laurvig, in southern Norway, has been found in the drift of Denmark, in Germany, and even in Yorkshire, England. Drift deposits, when separated by an intervening stratum of non-glacial material, show changing conditions as to the advance and retreat of the ice sheet. See **GLACIER**; **GLACIAL PERIOD**; **DRUMLIN**; **ESKER**.

DRIFT OF A PROJECTILE. The divergence of the projectile from the plane of departure due to the rotation of the projectile, its ballistic character, and the resistance of the air. It is generally in the direction of rotation, except for extreme elevations of high-angle fire, in which case it may be opposite to the original direction of rotation. For the United States service rifled guns it is to the right. It may be expressed either in yards or angular measure. See **BALLISTICS**, especially the section on *Exterior Ballistics*.

DRIFTWAY (AS. *drifan*, to drive). A right of way for driving cattle. Such a right exists, as a *public right*, in highways, unless restricted by statute or the terms of the dedication of the

highway, or it may exist as an *easement* over the land of another, acquired by grant or prescription. Not every easement of a way is a driftway, however, nor even every general right of way—the latter being commonly restricted to the more usual purposes of a way, as passing and repassing on foot or with horses and wagons. A way "for all purposes" has, however, been held to include a driftway. See **EASEMENT**; **HIGHWAY**; **WAY**.

DRILL (from Dutch, Ger. *drillen*, to drill, connected ultimately with AS. *gyrelian*, to bore, Eng. *thrill*). In the broadest meaning of the word a drill is a tool used in boring or making holes in rock, metal, bone, ivory, wood, etc. Drills for boring wood are described under **BORING MACHINES**. Rock drills, or rock-drilling machines, are a separate class of tools and are described separately below. Drills for metal, bone, ivory, etc., are made in several forms. One form consists of a square steel bar flattened out at the cutting end. This end is brought to an angular point like a spearhead, and the cutting edges forming the angle are beveled in opposite directions. Those which have a projecting pin in the centres and chisel-shaped cutting edges on each side of the pin are called centrebits. There are various contrivances by which the drills are made to revolve. For drilling iron, steel, and large brass work, the drilling machine (see **METAL-WORKING MACHINERY**) is commonly used. The best and most generally used drills for small boring are called twist drills, which have many advantages, over the flat drills described above. Twist drills are made from steel rods of uniform diameter throughout their length. Upon the rod two spiral grooves are cut, each starting at the cutting edge at diametrically opposite points. At the end of the drill the grooves almost meet in the centre of the rod, but grow shallower as they continue. The cutting edges are ground on the end of the rod, and the borings escape through the grooves, which constantly carry them away from the cutting edge, thus preventing . . .

Rock Drills. These may be subdivided into two general classes, percussion and rotary drills; they may be operated either by hand or by mechanical means. With the percussion drill the advance in the rock is made by striking the face of the hole with a chisel bit, whereas in the rotary type it is made by the grinding or milling action of an annular bit forced against the face of the hole.

PERCUSSION DRILLS. The simplest form of percussion drill operated by hand is known as the hand drill. It consists of a bar of steel having a chisel-shaped cutting edge which is struck with a hammer and slowly rotated between each striking. From one to three men are employed in this work; when more than one man is employed, one man turns the drill and adds water to the hole, while the others strike the drill. In soft formations holes can be drilled by merely churning and rotating a heavy bar of drill steel. This practice, known as churn drilling, is very common when a comparatively small amount of drilling is to be done. Mechanical means are employed for large scale work in both cases.

Power Percussion Drills may be subdivided into the reciprocating and hammer types. The former may be operated either by steam or by compressed air, whereas the latter, which is

of recent invention, can be operated only by compressed air. When compressed air is used, it is necessary to store it in a reservoir where the precipitated moisture resulting from compression can be drawn off; otherwise the air delivered to the drill will be wet, and on expansion of the air this moisture will freeze, causing trouble at the drill. (See AIR COMPRESSOR.) The first American reciprocating percussion drill was patented by J. J. Couch, of Philadelphia, Pa., in March, 1849. In May of the same year Joseph W. Fowle, who had assisted Couch in developing his drill, patented a reciprocating drill of his own invention. The Fowle drill was improved by Charles Burleigh and was first used in the Hoosac Tunnel. In Europe Caré patented a reciprocating drill in France in October, 1856. This invention was soon followed by several others; but it was not until Sommeiller's drill, patented in 1857 and perfected in 1861, was used on the Mont Cenis Tunnel that the problem of a reciprocating drill was practically solved abroad. Since that time numerous reciprocating-drill patents have been taken out in both America and Europe.

A *Reciprocating Drill* consists of a cylinder secured to a cradle, or shell, which in turn is mounted on either a tripod or a column. A long piston rod which works in the cylinder is supported in such a manner that a drill clamped to the end of the piston rod alternately strikes and is withdrawn from the rock as the piston reciprocates back and forth within the cylinder. Means are provided by which the piston rod and drill turn slightly on their axis after each stroke, and also by which the drill is put forward or advanced as the depth of the hole increases. There are various special forms of reciprocating drills, which differ from each other chiefly in the methods by which the valve is operated. All of these drills work either with direct steam pressure or with compressed air. The illustration is a longitudinal section, showing the interior construction of a common form of reciprocating drill to be operated by steam or compressed air. The steam or compressed

air is admitted at *A* to the chest, *B*. From *B* the slide valve, *C*, by moving back and forth, admits the steam or air behind, first, one end and then the other of the long-barrel piston, *D*. This slide valve is operated by the three-arm rocker, *E*, which is swung to and fro by the movement of the piston.

The *Hammer Type* of percussion drill was originally designed for the use of the machinist for calking, chipping, and riveting in boiler work. George Lyner, of Denver, seeing the advantage of such a type of drill, placed on the market in 1898 the first successful hammer drill. Further improvements have resulted in the successful development of a light-weight one-man hammer drill, commonly called a butterfly drill, which consumes only about 50 per cent of the amount of air per foot drilled as

the reciprocating type. One of the latest types is a self-rotating hammer drill, especially designed for back stopping. This drill consists of a barrel or cylinder in which a hammer pis-

SELF-ROTATING PNEUMATIC HAMMER DRILL.
a. Elevation. b. Section.

ton is operated by air. The steel is inserted in one end of the cylinder, and to the other end is attached a telescope tube by means of which the cylinder holding the piston and drill steel is moved forward by compressed air as the drill hole is advanced. The drill steel is rotated mechanically by means of a sleeve connection between the drill steel and a ratchet bar, quite similar to that of the reciprocating type. The shank of the drill steel extends a sufficient distance into the cylinder to receive the blow of the rapidly moving hammer piston. This type of drill is meeting with much favor.

Electric Percussion Drills are built, but have not up to the present time met with favor. The reciprocating and hammer drills are used almost entirely for holes for blasting purposes.

Churn Drilling.—For drilling vertical holes of larger diameter, such as artesian wells, oil wells, and prospecting ore deposits when the ground is badly fractured or fissured, the churn drill operated by power is used. The surface plant consists of a high derrick, an engine operating a walking beam, and a steam boiler. A churn-drill equipment with derrick engine and boiler may be, for ready transportation, mounted on wheels. The drilling tools, known as a string of tools, consist of a rope socket, sinker bar, jars, auger stem, and bit. The jars are placed midway in the string of tools and resemble two long links of a heavy chain; their object is to permit of an upward blow in case the drill becomes stuck in the hole. The drill rope, which is coiled on the

drum, passes from the drum up over a sheave in the top of the derrick and down to the string of tools in the hole; for drilling, this rope is attached near the surface, by means of a clamp, to the temper or feed screw, which in turn is attached to the walking beam. Water is added to the hole while drilling, and the crushed rock or sludge is extracted by use of a sand pump.

Many other types of churn drills are employed, which are discussed in various special works on this subject. See WELL SINKING.

ROTARY DRILLS. When it is desired to receive a core or section of the formation drilled to examine the structural or mineralogical character, core drills of the rotary type are used. These may be subdivided under the two heads of diamond drills and shot drills. Instead of making the advance in the rock by percussion, the rotary drill, consisting of hollow drill rods to which is attached an annular bit, makes its progress by a boring action produced by rapid rotation. Only an annular ring is cut in the formation by the bit, thereby leaving a core or section of rock which enters the opening in the bit and drill rods. On withdrawing the rods from the hole the core of rock which is incased in the rods is brought to the surface, where it can be examined, sampled for assay, or stored in a core box for future reference. The rotary drill is largely used for prospecting mineral deposits, testing bridge foundations and concrete, and general exploration work when one desires a sample of the formation from below the surface. The two heads under which the rotary drill may be subdivided are known as the diamond drill when diamonds are set in the bit, and the shot drill when a soft steel bit is used and the cutting is done by the addition of steel shot.

Diamond Drilling.—The application of the diamond drill is for deep holes less than 2 inches in diameter. The cost of diamonds prohibits the drilling of larger holes. The angle of the hole should be below the horizontal if possible, although holes have been drilled at angles above the horizontal and a few almost approaching the vertical. Holes exceeding 5000 feet in depth have been drilled in South Africa. The drilling equipment consists of a water swivel, drill rods, core barrels, core lifter, and diamond bit. The drill rods consist of heavy pipe, a core barrel of extra heavy pipe about 10 feet long, a core lifter containing a steel ring for gripping the core of rock as the rods are withdrawn from the hole, and a bit, consisting of an annular ring of soft steel in the face of which is set an even number of diamonds in such a way as to cover the entire annular face. An eight-stone diamond bit will contain about 12 carats and will have a value of from \$700 to \$800. The drill is rapidly revolved, and the cutting is done by the diamonds. It is necessary to feed water constantly through the rods

DIAMOND DRILL BIT.

to the face of the bit to wash away the pulverized rock and keep the bit and diamonds cool. The pressure of the drill bit on the face of the

hole is regulated by a hydraulic feed or an adjustable screw feed.

Shot Drills.—For vertical or nearly vertical holes exceeding 2 inches in diameter the shot bit has replaced the diamond bit. In addition to the uses to which the diamond drill is applicable, the shot drill can be used for drilling ventilating holes in mining operations, and it has been used by the United States government in drilling a short hole 30 inches in diameter at an angle of 30°. At Astoria, L. I., a 10-inch vertical hole was drilled to a depth of 2002 feet with a shot bit. The drilling tools consist of a water swivel, drill rods, calyx, core barrel, and bit. The drill rods consist of heavy pipe much smaller than the diameter of the hole. The calyx is a pipe only slightly smaller than the diameter of the hole surrounding the drill rod, and serves as a cup or reservoir to catch the sludge as it is washed from the face of the hole. The core barrel is a heavy pipe attached to the lower end of the calyx to retain the core after it is cut. The bit consists of soft steel. The drill is rapidly revolved, and the cutting is done by a milling action of steel shot fed into the drill rods and washed to the cutting face of the bit. It is necessary to feed water constantly through the rods to the face of the bit to wash away the pulverized rock and keep the bit cooled. The feeding, or advancing, of the drill rods is similar to that of the diamond bit.

For additional information on rock drills, consult: Redmayne, *Modern Practice in Mining* (4 vols., New York, 1911); Foster, *Elements of Mining and Quarrying* (ib., 1905); Dana and Saunders, *Rock Drilling* (London, 1911); and the catalogues and bulletins of manufacturers.

DRILL (Dan. *drille*, bore, Dutch *drillen*, to bore). In agriculture, an implement employed for planting, or drilling, seeds in regular rows as distinguished from hand or broadcast sowing, which was almost universally practiced until about the middle of the last century. It is said that a sort of drill plow was developed in Assyria long before the Christian era and that the Chinese used a similar implement 3000 to 4000 years ago. Jethro Tull, however, early in the eighteenth century invented the first implement in any way comparable with the modern drill and showed its merit in the culture of grain and root crops. The first patent for a seed drill granted in America was to Eliakim Spooner in 1799, but nothing is now known of the nature of his device. Many patents followed, but M. and S. Pennock, of Pennsylvania, were probably the first (in 1841) to manufacture and sell any considerable number of seed drills. A great variety of drills are now in use, distinguished from one another mainly by the type of furrow opener or covering device used, as, e.g., hoe drills, shoe drills, double and single disk drills, press-wheel drills, and those using a chain-cov-

BIT FOR SHOT DRILLING.

ering device. Drills with a single-disk furrow opener and a chain-covering device are coming to be preferred to other forms. Drills are sometimes adapted to the simultaneous distribution of fertilizers and seed, but this is accomplished by means of a fertilizer attachment, as the two cannot be effectively applied by means of the same mechanism. One great recommendation of drilling is that it effects a considerable saving and more uniform distribution of seed, and a further advantage is that it permits cultivation and hence promotes conservation of soil moisture. See IMPLEMENTS, AGRICULTURAL.

DRILL. A general title for the various systems of exercises and methods of instruction by which organized bodies of men are made uniformly efficient and effective for the purposes of the organization of which they are a part. Specifically it has direct reference to the different details of training by which soldiers and sailors are organized and qualified for their duties. In the United States army the manuals for the different arms of the service are called *drill regulations*. These include not only *drill proper*, i.e., disciplinary exercises designed to teach precise and soldierly movement and subconscious obedience on the part of the individual soldier, but also *field and combat exercises*, designed for the tactical training of officers and organizations. (See INFANTRY; CAVALRY; FIELD ARTILLERY; COAST ARTILLERY; DRILL REGULATIONS.) The various European manuals of drill were based originally on the Prussian system of Frederick the Great and have been adapted since to such particular needs of the nations as have been dictated by national evolution and the improved inventions of modern scientific warfare. See TACTICS, MILITARY; MANUAL OF ARMS.

In the United States navy the drills are very numerous. In addition to the fleet or squadron drills, which comprise fleet tactics, battle tactics, and numerous special exercises, the drill of crews of ships comprise: clearing ship for action; general quarters (drill at stations for battle); fire quarters and fire drill; collision drill; battery drill, including drill at the heavy guns and secondary battery and supply of ammunition, instruction at the guns, etc.; torpedo drill and instruction; target practice (q.v.), with all calibres of guns, with full-calibre ammunition, subcalibre ammunition, record practice, preliminary practice, battle practice, small-arm practice, aiming drill, etc.; field-artillery drill with 3-inch field guns; infantry drill, including manual of arms and tactics, and exercise as a landing party or body of infantry making a landing and then operating on shore; boat drills, exercise with oars, with sails and tactical drill; also many other special drills, as coaling-ship drill, "man overboard," etc. In the older ship there are also sail drills, spar drills, etc. See GUNNERY; TACTICS, NAVAL.

DRILL. Any of several small gastropods which bore through the shells of other mollusks and suck out their juices, such as species of *Naticea*, *Purpura*, *Anachis*, *Astyris*, *Tritia*, *Ilyanassa*, and others. The most numerous in the waters off the east coast of the United States, and most troublesome, is *Urosalpinx cinerea*, which is exceedingly destructive of oysters on cultivated beds. It is this which is the common "drill" of the oyster beds; and it is its eggs, laid in small vase-shaped capsules, which are often found in groups attached to the under surface of stones. The natural home of the drill is the

tide pools and weedy borders of rocky shallows, where barnacles, hydroids, anemones, rock-loving limpets, and other associated forms that find shelter among the algae afford it abundant food. Though this is precisely where the mussels grow till the rocks are almost black with them, it is said that they are never attacked by the drills. The increase of these mollusks when they colonize upon an oyster bed is very rapid, and the damage serious; but it is very difficult to combat them and perhaps impossible to get rid of them. Consult Goode, *Fishery Industries*, vol. i, p. 696 (Washington, 1884), and Ingersoll, *Oyster Industry of the United States* (ib., 1882).

DRILL (from *mandrill*, baboon, probably a West Indian word; divided by popular etymology into *man* + *drill*). A West African baboon (*Cynocephalus*, or *Papia, leucophæus*), similar to the mandrill (q.v.). See BABOON, and Plate of BABOONS.

DRILL (abbreviation of *drilling*, Ger. *Drillich*, OHG. *drillich*, ticking, from Lat. *trilex*, three-threaded, from *tres*, three + *licium*, thread; associated by popular etymology with Ger. *drei*, three + termination *-ing*). A fine heavy twilled linen or cotton fabric of a satiny finish.

DRILL REGULATIONS. Official manuals prescribing for the different arms of the service the methods of training and instruction, their formations, manœuvres, and ceremonies, and in a limited sense their battle tactics. The forms in which the units of organization learn their duties and perform them, at rest and in motion, are embodied in the drill regulations prescribed by the various nations. They are, from their nature, next to organization, the foundation for the tactics of an army.

Drill regulations are undergoing constant change, due to improvements in firearms and the experiences of the most recent wars as well as the improvements in other fields of science. Those for the various branches of the line—cavalry, infantry, artillery—are comparatively stable, although even these are changed almost every decade. Those for coast artillery must change with every alteration or improvement in the piece, its carriage, the emplacement accessories, and the electrical power and communication systems. See ARMY ORGANIZATION; DRILL; TACTICS, MILITARY.

DRUMYS. See WINTER'S BARK.

DRINKER, HENRY STURGIS (1850–). An American university president, born in Hongkong, China. In 1871 he graduated from Lehigh University, and in 1878 he was admitted to the bar. Between these dates he had had charge of the building of the Musconetcong tunnel for the Lehigh Valley Railroad; by this road he was later retained during a long period as general solicitor (1885–1905). In 1905 he became president of Lehigh University. He received the degree of LL.D. from Lafayette College, Franklin and Marshall College, and the University of Pennsylvania. Besides editing a revised edition

A DRILL.
Shell and Egg Capsules (a) of *Urosalpinx cinerea*.

of Ball's *General Railroad and Telegraph Laws of Pennsylvania* (1884), he is author of *Tunneling, Explosive Compounds, and Rock Drills* (1878; 3d ed., 1882).

DRINKER MOTH (so called from its long proboscis). An English foliage-destroying moth (*Odonestis potatoria*), closely allied to the egger.

DRINKHOUSE, EDWARD J. (1830-1903). An American clergyman and editor, born in Philadelphia. In 1850 he joined the Maryland Conference of the Methodist Protestant church. Ill health compelled him to retire from the ministry for a time, and he went to California. In 1865 he received the degree of M.D. from Toland Medical College, San Francisco. He was editor of the *Methodist Protestant* for 18 years and was one of the foremost leaders of his denomination, whose history he published as *History of Methodist Reform Synoptical of General Methodism, 1703 to 1898, with Special and Comprehensive Reference to its Salient Exhibition in the History of the Methodist Protestant Church* (2 vols., 1899).

DRINKING USAGES. As religious observances, drink offerings were common among the ancients, both Jews and pagans. To mark the spot where he communed with God, Jacob set up a pillar of stone and "poured a drink offering thereon" (Gen. xxxv. 14), and women are said to have poured out drink offerings unto other gods (Jer. vii. 18). On occasions of solemn prayers and before their eating and drinking, the Greeks and Romans poured from the cup to the ground a small quantity of the liquid—either undiluted wine, milk diluted with water, or water flavored with honey. A relic of the custom was recently noted in the island of Samos. The health-drinking custom comes from antiquity. Homer's Odysseus, when about to leave the Phæacians, rises from the couch and places the drinking bowl in the hands of Alcinous' wife with the words "I drink to you; be happy." So, too, with the early Romans, the drinking of healths was a common custom, simply observed with a homely formula. Plato and Xenophon have described the famous *symposia*, or drinking parties, of the Greeks, which, under the name *commissatio*, came into vogue in Rome under the Empire. These followed the feast and were enlivened by games, riddles, and the music of the lyre. Wine and water were mixed for the whole company in a *crater* (bowl), from which the *pocula* (cups) were filled. One of the party formally elected to the office of *arbiter bibendi* (master of the revels) decided the strength of the beverage, the toasts to be drunk, and other matters connected with the festivities; or less formally each guest suited his taste in the mixing of the wine and water. Frequently the number of letters in the name of the one whose health it was proposed to drink decided the *cyathi* (measuring cups) of wine (Martial, xi, 37). When a person drank wine with another, he first tasted of the cup himself and then handed it to his friends, with the words *Propino tibi* (I drink to you)—or, more colloquially, *Bene vos*—and received his cup in return. Among the Celts and Germans a similar custom existed, but without such ceremony. There was a common bowl of wine; the first to drink took a sip, turning to his neighbor with an "I drink to you," and the bowl made the rounds of the table. There was no trace of the libation to the gods which was customary among the Greeks and Romans.

The Christians took up the pagan custom and in their feasts expressed good wishes for the bodily health and future welfare of their friends. An abuse crept in which savored of idolatry and profanation—the drinking to the dead and to the saints. This latter custom was anathematized by a council at Nantes and gradually fell out of use; but drinking to the dead is not uncommon even to-day. It has been said that the practice of saying "I'll pledge you" originated during the tenth century, when the English were fearful of the treachery of the Danes. When one of the company stood up to drink to another, the bow raised high with both hands and his back exposed to a murderer's blow, his companion next him stood up also and raised his drawn sword to defend him while drinking; he was his *pledge*, responsible for his protection. The *wassail bowl* became the *poculum caritatis* of the monastery. On New Year's Day it was placed before the abbot, and from it the superior drank to all, and the rest in succession to each other. Hence the origin of the "grace cup" of the universities and the "loving cup" of the corporation feasts in London, whose formalities recall those connected with the ancient wassail bowl. After dinner the master and wardens "drink to their visitors in a loving cup and bid them all heartily welcome." The cup (a silver flagon containing warm spiced wine) then circulates round the table, the person who pledges standing up while his neighbor drinks to him.

Excessive gallantries accompanied the drinking of healths during Elizabethan times. Just as the Roman lover wrote his mistress's name with wine on the tables, the English gallant would write it with his blood or even stab his arm and drink to her health in his blood. Drinking healths on the knees, often with the knees bared, was of common occurrence. And doing honor to a lady by tossing into the fire some jewel or ornament of dress, with a bidding to their companions to follow, was a custom among lovers even as recent as the nineteenth century. The Puritans would have no drinking of healths but with the restoration of Charles II the custom was again carried to excess. See TOAST.

Many old drinking usages, still kept alive by the class that clings to old traditions, are connected with occasions of birth, baptism, marriage, and death. The gloomy festivity of the *lykewake*, or wake, over the corpse of the deceased in Scotland and Ireland, and the former drinking of the *dredgy* (dirge) after funeral solemnities, are relics of very ancient customs.

As regards miscellaneous drinking observances at one time common, we can refer but to few of the more prominent. Apprentices, on being introduced to a workshop, paid so much entry money to be spent in drink. Similar exactions were made from journeymen on entering a new employment. This was called "paying their footing." When Benjamin Franklin, on getting employment in a printing office in London, refused to comply with this mischievous custom, he experienced, he tells us, a variety of petty annoyances. Among shipwrights the penalty of non-payment was flogging with a handsaw from time to time and other maltreatment. Happily the abolition of these usages has kept pace with the increasing intelligence of the working classes, but even nowadays the last student entering the French *atelier* must treat the rest. From the novels of Smollett and others, it appears that prisoners, on being lodged in jail, were obliged

to pay *garnish* for drink to the brotherhood of which they had become members. The efficacy of modern prison discipline has done away with such exactions.

The giving of *vails* (Lat. *vale*, farewell) to servants on quitting a gentleman's house—a custom which became so intolerable in the eighteenth century as at length to be given up by universal consent—meant, doubtless, a gift to be spent in drink to the health of the donor and was analogous to the custom of giving a *Trinkgeld* in Germany and a *pourboire* in France to servants, drivers of carriages, and others. There were at one time numerous drinking usages connected with departures. We need notice only the *bonailie* (Fr. *bon aller*), or as it is sometimes called, a *foy* (Fr. *voie*), a festive drinking at the going away of servants or of persons of higher rank—a custom once common in the Lowlands of Scotland; also the *stirrup cup*, or, as it is called in the Highlands, *deoch an dorris*, or drink on getting on horseback and being ready to set off. For the decline of drinking habits in general, see the article *TEMPERANCE* in this *ENCYCLOPÆDIA*. Consult: Dunlop, *Drinking Usages of Great Britain* (London, 1839); Mew and Astion, *The Drinks of the World* (ib., 1893); Hackwood, *Inns, Ales, and Drinking Customs of Old England* (New York, 1909).

DRIPMOLDING. See *DRIPSTONE*.

DRIPSTONE. A projecting molding or tablet placed over the head of a Gothic doorway or window for the purpose of throwing off the water, whence it is also known as a water table or water-lip. Though such was, no doubt, its purpose at first, it latterly became a mere ornamental appendage, which served to enrich and define the outline of the arch. It does not generally extend lower than the springing of the arch. When the tracery extends to a lower level, the external dripstone usually accompanies it, and Parker mentions that at the north doorway of Otham Church, Kent, it descends the whole length of the jamb. The dripstone is less common a feature in Continental than in English Gothic.

DRISLER, dris'ler, HENRY (1818-97). An American classical scholar, born on Staten Island, N. Y. He graduated at Columbia in 1839, was appointed tutor of Greek and Latin there in 1843, and adjunct professor of Greek and Latin in 1845. From 1857 to 1867 he was professor of the Latin language and literature and from 1867 until 1894 Jay professor of the Greek language and literature. In 1894 he became professor emeritus. He was acting president of Columbia in 1867, during the absence of President Barnard as United States Commissioner to the Paris Exposition of that year, and again in 1888-89, after the retirement of President Barnard and previous to the election of President Low. In 1890-94 he was the first dean of the Columbia School of Arts. He assisted Anthon (q.v.) in the preparation of a series of textbooks and brought out an American edition, with corrections and additions (1851), of the *Greek-English Lexicon* of Liddell and Scott. In 1858 he revised and enlarged Yonge's *English-Greek Lexicon*. Later, he rendered such important service in the revision connected with the sixth, seventh, and eighth Oxford editions of the *Greek-English Lexicon* of Liddell and Scott (1874; 1883; 1897) that these editions show his name on the title-page.

DRIVER, dri'vēr, SAMUEL ROLLES (1846-1914). An English biblical scholar, born at Southampton. He graduated B.A. at Oxford (1869), was fellow and tutor (1870-83), succeeded Pusey as regius professor of Hebrew and canon of Christ Church, Oxford, in 1883. Among his publications are: *A Treatise on the Use of Tenses in Hebrew* (1892); *Notes on the Hebrew Text of the Books of Samuel* (1890); *Isaiah: His Life and Times* (1893); *An Introduction to the Literature of the Old Testament* (1897); commentaries and annotations on Leviticus (1894-98), Deuteronomy (1895), Joel and Amos (1897), Daniel (1900), Genesis and Exodus (1911). With Francis Brown and Charles A. Briggs he published *Hebrew and English Lexicon of the Old Testament* (New York, 1906).

DRIVER ANT, or **VISITING ANT**. A West African doryline ant (*Anomma arcens*), nearly $\frac{1}{2}$ inch long and blind, which goes about, mainly at night, in "armies" that destroy all the smaller creatures overtaken. When they reach a village, the negroes are obliged to quit their houses as long as the ants remain, and "all the rats, mice, lizards, cockroaches, and other vermin . . . are either compelled to decamp hastily or are caught, killed, and devoured." They are said to have no fixed abodes, but to follow a nomadic life, crossing rivers by clinging to one another in a living chain, or bridge, over which others pass; or, when aroused by floods, drifting into spherical masses and floating in the drift ashore. A very complete account of their habits is given by Wilson in *Western Africa* (New York, 1856), from which the following facts are quoted: "When about to cross a well-trodden path where they [the column] are likely to be disturbed, the soldiers weave themselves into a complete arch, extending across the whole width of the path, under which the females and the laborers bearing the larvæ pass without the least exposure. I have frequently put the end of my cane under the arch and raised it full five feet from the ground without letting a single ant fall." Also consult: Savage, "On the Habits of the Drivers, or Visiting Ants of West Africa," in *Transactions Entomological Society, London*, vol. v (London, 1847), and *Proceedings Academy of Natural Science, Philadelphia*, vol. iv (Philadelphia, 1847); Wheeler, *Ants* (New York, 1910).

DRIVING (from *drive*, AS. *drifan*, Icel. *drifa*, Goth. *dreiban*, OHG. *triban*, Ger. *treiben*). The art of driving one or more horses with the greatest security and comfort to all concerned is as important to the horse as to the driver; and yet, notwithstanding the experience of centuries, its finer points remain unknown to many men and women who are in the regular habit of driving, whether for business or pleasure. Pleasure driving is usually confined to a single horse, or a pair in double harness side by side, or a pair tandem fashion. Modern conditions of road and street traffic compel the adoption of definite rules for each of these and demand that the thoroughly equipped driver be at all times ready and able to adjust himself to circumstances as they vary from moment to moment. Above all, a connection or bond of sympathy should be established between the driver's hands and the horse's mouth, so that prompt indication may be made of any intention to change the direction. In driving a single horse the

driving, or left, arm should be held easily and sufficiently forward for the right arm to be able to come to its assistance, with sufficient space between the rein hand and the body to insure the possibility of drawing the reins in without swaying the body backward. The third or fourth finger should press on the reins, preventing them from slipping. When the right hand is needed to aid the left, the second, third, and fourth fingers of that hand are placed between the reins, and the first and second placed on the right rein, grasping it, but keeping each rein of equal length. To turn to the right, bend the wrist over in such a manner as to bring the thumb undermost towards the left hip; and for a turn to the left, bring the little finger undermost and incline it towards the right hip. The driving (left) hand must be held straight in the centre of the body, with the knuckles of the hand to the front, and the forearm exactly square to the upper arm, the elbow and back of the fingers (when shut over the reins) lightly touching the (driver's) coat. The whip is held in the right hand, grasped in such a manner as will give it the best balance, either for carrying or for service. With a well-made properly balanced whip this would be about 15 or 16 inches from the butt. If bearing reins are used, care must be taken that they are never so short as to fret the horse. A slight drawing of the reins—pulling them sufficiently taut gently to “feel” the horse's mouth—indicates to the properly trained horse the signal to move off. *Driving two horses abreast* is effected in the same manner, there being but two reins in the driver's hands. When two horses are driven *tandem* fashion, the one before the other, four reins come into use, and much of the practice of four-in-hand driving applies.

For *coach*, or *four-in-hand*, driving the reins should be of a width and thickness regulated by the length of the driver's fingers. Before mounting take in the left hand the rein that draws through the centre of the terret of the left-hand wheeler's pad (this is the near-side leader's rein) and draw it until it bears on the bit. Next pull the right leader's rein through in the same manner and pass them to the right hand. Then pull first the left and then the right wheeler's reins through the finger spaces of the left hand. Having assembled all the reins in the left hand, pass them between the corresponding fingers of the right hand, leaving the left hand free to grasp the rail and mount to the driving seat. In mounting the left foot is placed on the wheel box, the right on the splinter bar, followed by the left foot on the step and the right foot on the footboard of the box, whereupon the driver speedily seats himself. Once seated, the feet are brought close together; the left hand so placed that it will be on a level with the lowest vest button, the forearm as nearly as possible horizontal, and, similarly, the hand in the centre of the body, which it touches with the back of the fingers, the knuckles being straight to the front.

The wrist must be able to work backward and forward like a spring. The horses are notified to start by lightly drawing in the reins so as to secure a slight pressure on every horse's mouth, after which a sign or a cry will notify the grooms to stand clear, and the horses will move off together. The team must be started at a walk, and the driver be prepared to hold in the leaders. Never use the whip unnecessarily, and before doing so, in any event, have all the horses

well in hand. To shorten the reins, take them between the fingers of the right hand and pull them back through the fingers of the left. To ease the left hand, change the reins into corresponding position in the right, but only when on a straight, clear road. Keep the leaders slightly in, so that their traces are slack. Go uphill at a trot, or even at a gallop, as it keeps the team more even. Downhill the horses should be well in hand. To turn to the right, take the right-hand leader's and wheeler's reins about 8 inches away from the left hand, and pull them until the right hand is near the body; drop the left hand gently, then, as the team comes round to the right, steady the right-hand horses, ease out the reins of the left-hand ones, and the team will straighten out. The turn to the left is a reversal of these methods. Stop gradually, taking in first the leaders' reins, then the wheelers'. Bring the team down to a slow trot and let them be almost at a walk before coming to a full stop. Pass the reins to the right hand and dismount.

The position of the reins in the driving hand is a much-disputed point, and one to which too much importance cannot be attached. Driving in America has naturally been considerably influenced by the methods employed in England; and the “tooling” of fashionable coaches is still apt to be after the English fashion. The strictly American method of holding the reins is seen in Figs. 1 and 3, the latter being known as the “clubbed hand.”

When all the reins are held in one hand, a rein in each finger space, it is called a “full hand” (Fig. 2), a method once very popular on the continent of Europe and even now considered good form in France. The great objection to the method, however, is that the off-wheel rein, on top of the little finger, cannot be firmly held, owing to the insufficiency of strength in that finger. In Switzerland and Italy the professional coachmen employ many different methods of handling, although all of them seem to be opposed, in practice at least, to the old French custom, or “full hand,” already explained. The method of the Saint-Moritz diligence (Fig. 4) is perhaps the best method employed on the Con-

FIG. 1.

FIG. 2.

FIG. 3.

tinent and resembles the English in that the lead reins and the wheel reins each adjoin—a method also employed by professional stage-coach drivers in America. In six-horse driving the English method is practically universal (Fig.

5). The lead reins, together with those of the middle pair, are held in the same position as would be the leaders and wheelers in four-horse driving; and the reins of the wheelers are then placed on the two sides of the third finger, below

FIG. 4.

FIG. 5.

all the others. Much more easy of control and handling is the method of harnessing three abreast on the lead, with two at the wheel. Consult: Ware, *Driving* (New York, 1903); Anderson and Collier, *Riding and Driving* (ib., 1905); Beach, *Riding and Driving for Women* (ib., 1912).

DRIVING, FURIOUS. The offense of driving or otherwise propelling vehicles over a public road or highway at a dangerous rate of speed. Furious and reckless driving on thronged thoroughfares is an indictable offense at common law, punishable by fine and imprisonment. The offense has become statutory in England, and prosecutions are now usually brought under the statutes governing the matter, though the common-law remedy is still available. In the United States such legislation is common and has been sustained as coming within the police power of the State legislatures. In cities and incorporated villages the rate of driving and of propelling street cars, bicycles, automobiles, and other vehicles is usually regulated by municipal ordinances, having the force of legislative enactments, fixing the maximum rate of speed permitted and prescribing the penalty for a violation.

DROBISCH, drō'bish, GUSTAV THEODOR (1811-82). A German poet and author, born in Dresden. In 1847 he became the editor of the *Zeitung für die elegante Welt*, at Leipzig, which he conducted for 13 years. He was widely celebrated as a humorist, was editor of the *Witz- und Karrikaturen-Magazin*, and published the following contributions to humorous literature: *Amarillen und Bartnelken* (1857); *Humoristische Liedertafel* (1863); *Bunte Glasuren* (1865); *Komische Vorträge* (5th ed., 1892). He also wrote comedies, opera texts, tragedies, and novels.

DROBISCH, MORITZ WILHELM (1802-96). A German philosopher and mathematician. He was born and educated at Leipzig and in 1826 became professor of mathematics and philosophy at the university in that city. He began his literary career as a disciple of Herbart, and though in his later philosophical works he showed decided independence of thought, he remained Herbartian in his general attitude. He was also distinguished as a mathematician and psychologist and was especially interested in the application of mathematical laws to psychic phenomena. His philosophical writings include: *Beiträge zur Orientierung über Herbart's System der Philosophie* (1834); *Neue Darstellung der Logik nach ihren einfachsten Verhältnissen* (1866; 5th ed., 1887); *Grundlehren der Re-*

ligionsphilosophie (1840); *Empirische Psychologie nach naturwissenschaftlicher Methode* (1842; 2d ed., 1898); *Erste Grundlinien der mathematischen Psychologie* (1850); *Kants Dinge an sich und sein Erfahrungsbegriff* (1885). Consult Heinze, *Moritz Wilhelm Drobisch* (Leipzig, 1897).

DROGHEDA, drōg'e-dā (Oir. *Droicheadatha*, bridge of the ford). A seaport, municipal borough, and market town on the southern border of County Louth, Ireland, situated on both sides, but chiefly north, of the Boyne, 4 miles from its mouth, and 31 miles north of Dublin (Map: Ireland, E 3). The Dublin and Belfast Railway crosses the Boyne here by a viaduct 95 feet high. There are cotton and flax manufactures, flour mills, saw mills, tanneries, breweries, a soap factory, and an iron foundry. It has a considerable trade, chiefly with Liverpool, principally in corn, meal, flour, cattle, provisions, linen, hides, and butter. Great quantities of ale are exported. Each census since 1841 shows a falling off in the population. At that date it contained 17,300 inhabitants, while in 1891 the population numbered 13,708; in 1901, 12,760; in 1911, 12,501. Drogheda was a political and ecclesiastical centre as early as the twelfth century. Its antiquarian remains include St. Mary's Abbey, founded in the reign of Edward I, the Magdalen tower of the Dominican priory where the Irish chieftains surrendered to Richard II, the "Tholsel," or town hall, and the ruined West Gate and perfect St. Laurence Gate of the ancient fortified walls, parts of which remain. The two divisions of the town were united by a charter from Henry IV in 1412. Poyning's Laws were enacted in 1495 by a parliament assembled here. In 1649 Cromwell stormed the town and slaughtered its inhabitants. It surrendered in 1690 to William III after the battle of the Boyne, fought some 2 miles from the town. Consult Barnard, *The Siege of Drogheda* (Dublin, 1736).

DROGIO, drō'jē-ō. The name given by the fourteenth-century Venetian traveler Antonio Zeno to a vast country southwest of Estotiland (Labrador?). The land is probably mythical.

DROHOBYCZ, drō'hō-bēch. A town of Galicia, Austria, 1015 feet above sea level, situated near the left bank of the Tysmienica, a tributary of the Dniester, 40 miles south-southwest of Lemberg (Map: Austria, H 2). Its public buildings include a castle, surrounded by extensive grounds, and a handsome Gothic parish church of the fourteenth century. The chief industry is the preparation of salt from mines in the vicinity. Trade is carried on in grain, cattle, leather, paraffin, and petroleum. Pop. (commune), 1900, 19,146; 1910, 34,665.

DROIT D'AUBAINE, drwā dō'bān' (Fr., alien's law, Lat. *alibi nati*). A harsh rule of French law whereby all the property, real and personal, of an alien dying in France was confiscated to the crown. The rule was limited to property found within the jurisdiction of the crown and to foreigners who were domiciled within the territories of the French King. It had no application to travelers, foreign merchants trading in France but not residing there, nor to the representatives of foreign Powers. A few foreign nationalities, as the Swiss, Savoyards, Scotch, and Portuguese, were also exempted. It survived until 1819, when it was finally abolished. For the status of aliens generally, see ALIEN; CITIZEN; SUBJECT.

DROITWICH, droit'ich (OF., Fr. *droit*, right, customs duty + Eng. *wich*, *wick*, salt spring, Icel. *vik*, creek, Lat. *salinæ*, salt springs). A municipal borough in Worcestershire, England, 5½ miles north-northeast of Worcester, in the narrow valley of the Salwarpe, and on a canal connected with the Severn, which admits vessels of 60 tons (Map: England, D 4). It has direct communication, also, by means of other canals, with Birmingham and London and the intermediate district. Its chief trade is in salt, for which it has been famous from remote times. In the middle of the town, rising from a depth of 170 feet through beds of new red sandstone and gypsum, are the celebrated *wyches*, or brine springs, containing between 35 and 40 per cent of pure salt and yielding annually over 100,000 tons of salt, a large part of which is exported to foreign countries. The constant pumping of the brine causes the land to settle, which affects building foundations. The saline baths are much frequented. The town owns its gas and water supplies, but for many years has permitted the investment of nonlocal capital in the brine springs. Pop., 1901, 4201; 1911, 4146. The remains of a Roman villa, with tessellated pavements, etc., were found here.

DRÔME, drôm. A department in the southeastern part of France, bounded on the west by the Rhône (Map: France, S., K 4). Area, 2532 square miles; pop., 1901, 297,321; 1911, 290,894. Towards the east the surface is hilly, a spur of the Alps traversing the eastern limits and sending offshoots of about 3500 feet in average height westward across almost the entire area of Drôme. These heights, covered with forests of pine, oak, and beech, afford excellent pasturage in summer and autumn. The most notable rivers are the Drôme, from which the department takes its name, the Aygues, and the Isère. Vines and mulberry, chestnut, walnut, and olive trees are extensively grown. Commerce in wood, cattle, wines, and meal is carried on. In the production of mulberry leaves and in silkworm culture Drôme is one of the leading departments of France. Iron ore is abundant. The manufactures consist chiefly of woolen cloth, silk, hosiery, serge, cotton yarn, shoes, lumber, and machinery. Capital, Valence.

DROMEDARY, drôm'é-dâ-rî (OF. *drome-daire*, Lat. *dromedarius*, from Lat. *dromas*, Gk. *δρῶμας*, *dromas*, a running, from *δραμῆν*, *dramein*, to run). A name sometimes given to the Arabian, or one-humped, camel (*Camelus dromedarius*), but properly belonging to a variety of that species distinguished by slenderness of limbs and symmetry of form and by extraordinary fleetness, "bearing much the same relation to the ordinary camel as a race horse or hunter does to a cart horse." A good one is valued in Upper Egypt at from \$50 to \$75. The pace of the dromedary is a trot, which it can maintain for a prodigious length of time, often at the rate of 9 miles an hour for many hours together; while a journey of upward of 600 miles is performed at a somewhat slower rate in five days. Even its more rapid pace can be maintained for 24 hours at a stretch without sign of weariness and without stopping to bait; and if then it is allowed a little refreshment, of a ball of paste made of barley and powdered dates and a little water or camel's milk, it will resume its journey and go on with undiminished speed for 24 hours more. The jolting to the rider is terrible. The gallop is a pace unsuitable to the dromedary and

at which it very soon fails. See CAMEL, and Plate of CAMELS AND LLAMAS.

DROMIO OF EPH'ESUS and **DROMIO OF SYR'ACUSE**. In Shakespeare's *Comedy of Errors*, twin brothers who had been separated in childhood and, at the opening of the play, have become attendants, respectively, of Antipholus of Ephesus and Antipholus of Syracuse. The first named is thick-witted, the second is bright.

DRONE. See BEE.

DRONE (of a bagpipe). See BAGPIPE.

DRONE FLY (so called from its resemblance to a drone). A common cosmopolitan fly of the family Syrphidæ (*Eristalis tenax*). Its larvæ live in liquid filth and the putrefying carcasses of animals, breathing by means of a very elongated anal projection bearing spiracles at the tip; they are sometimes called "rat-tailed maggots." The fly somewhat resembles the honeybee, and this resemblance has given rise to the "Bugonia myth," which is found among many nations and is of ancient origin (Judg. xiv. 8), to the effect that honeybees may be born from filth or decaying bodies.

DRON'GO (Neo-Lat. *drongus*, from the Malagasy name), or **DRONGO SHRIKE**. A bird of the passerine family Dicuridæ, which is widely scattered throughout Africa and southeastern Asia and whose systematic position is undecided. The beak is very shrike-like, and beset with bristles at the base, in conformity with the insect-eating habits of the family. The plumage is invariably glossy black; the tail has 10 feathers, is forked, and the outer rectrices are often greatly prolonged, or curled or racket-shaped. These birds are wholly arboreal, active on the wing, restless and pugnacious, and nest in trees. Several genera and many species are recognized. Most of them inhabit India and Malaysia, but two species are natives of South Africa and one of Australia. See KING CROW.

DRONGO CUCKOO. An East Indian cuckoo (*Surniculus lugubris*), remarkable for so resembling the common drongo, or king crow (see DRONGO), as to deceive any but a careful observer. This instance of "mimicry" among birds is carried to the extent of imitating the forked tail, "a feature elsewhere entirely unexampled among the cuckoos." Ornithologists are of the opinion that this cuckoo, which is parasitic, selects the nest of the drongo, alone, as the receptacle for its egg. Several other species exhibit similar tendencies.

DRONTE. See DODO.

DRONTHEIM, drônt'hîm. See TRONDHEIM.

DROOD, EDWIN. See MYSTERY OF EDWIN DROOD.

DROOGENBROECK, drô'gen-brôök, JAN VAN (1835-1902). A Flemish poet whose pseudonym was JAN FERGUUT. He was born at Saint-Amands on the Scheldt and was educated at Lierre. He was for more than 22 years tutor and professor at a music school of Brussels. As a poet, he was the first to introduce Oriental verse forms into Dutch poetry, among his best productions of this kind being the celebrated *Makamen en Ghazelen* (1866; 2d ed., 1887). In 1886 he received a prize at Brussels for the treatise entitled *De toepassing van het Grieksche en Latijnsche metrum op de Nederlandsche Poëzie*. His poems of childhood, entitled *Dit zijn Zonnestralen* (1873; 6th ed., 1884), are popular. He also wrote the libretto to Lortzing's opera *Undine* (first performed in 1862).

DROPSY (bv aphæresis, for the older form

hydropsy, Lat. *hydropisis*, Gk. ὑδρωπῖσις, *hydropīsis*, ὑδρωπῖς, *hydrōps*, dropsy, from ὕδωρ, *hydōr*, water). A symptom occurring in several diseases. It consists of the effusion of watery fluid from the blood into the skin and subjacent tissues or into the cavities of the body. When the effusion is chiefly in the superficial parts and over the whole body, the dropsy is called *anasarca*; when it is in the peritoneal cavity of the abdomen, it is termed *ascites*; when in the chest, *hydrothorax*. Dropsy most commonly depends on disease of the heart (q.v.) or kidneys (q.v.) or upon the condition of the blood. Ascites is often caused by pressure upon the portal veins caused by a contracting liver, in a case of cirrhosis of that organ. The treatment of dropsy is chiefly by diuretics, diaphoretics, and cathartics, which remove the fluid from the tissues by unloading the blood of serum. In all cases of dropsy the internal organs should be submitted to a strict medical examination, and the treatment regulated accordingly. The fluid which is poured into the cavity of the pleura in pleurisy is not dropsical, but is an exudation of plastic material from the blood which has the property of becoming organized and forming adhesions between the lungs and the sides of the chest. In hydrothorax the fluid has no power of organization, although it contains blood serum. The presence of cysts in an ovary is called *ovarian dropsy*. Dropsy of the pericardium is called *hydropericardium*; of the cavity of a joint, *hydrops articuli*, or *hydrarthrosis*; of the cavity of the scrotum, *hydrocele*; of the skin and areolar tissue, *œdema*. If the cerebrospinal fluid be increased, the condition is called *hydrocephalus*. When internal medicines fail to remove an accumulation of dropsical fluid, or when it is due to pressure which cannot be relieved, it often becomes necessary to evacuate the fluid by tapping—i.e., by making an incision, or thrusting a hollow needle or trochar, into the cavity and drawing off the fluid. This operation, under antiseptic precautions, is practically free from danger and may be repeated from time to time by the surgeon as the pressure or weight of the accumulation becomes excessive. Dropsy of a limb is sometimes relieved by making several punctures through the skin. See **CEDEMA**.

DROPWORT. See **SPIRÆA**.

DROSERA. See **SUNDEW**.

DROSINIS, drō-sē'nīs, GEORGE (1859–). A modern Greek writer. He was born at Athens and, although originally a lawyer, later devoted himself entirely to belles-lettres. He lived in Germany from 1886 to 1888, during which time he edited *Esria* (*Hestia*), in which he translated several of his chief productions. His works, which are characterized by simplicity of language and genuine feeling, include five collections of lyrical poetry: *Spun Webs* (1880), *Stalactites* (1881), *Idylls* (1885), *Prince's Feathers* (1890), and *Light of Love* (1894); and the following prose writings: *Rural Letters* (1882), *Three Days in Tinos* (1885), *Tales and Reminiscences* (1886), and *Fables* (1889).

DROSOMETER (from Gk. δρόσος, *drosos*, dew + μέτρον, *metron*, measure). An apparatus for measuring the quantity of dew formed per unit area. The surface may be either a horizontal metal plate or a leaf hanging naturally, or a bit of wool or cotton representing a large surface of fine fibres. The measurement for a

given night should be made in the early morning, before the rising sun evaporates the dew. When the apparatus is made self-registering, the surface, with its accumulating dew, hangs at one end of a delicate balance or from a delicate spiral metallic spring and by its gradual sinking moves the index that makes the record on a moving sheet of paper. Although many forms have been suggested, yet none are found to give results that are comparable with each other from day to day, owing largely to the fact that the slightest change in the surface that receives the moisture alters the quantity of dew that is caught. Even the same bit of wool, when used day after day, changes its nature in this respect. If a metallic surface is used, its behavior must be compared frequently with a standard, partly because different metals have different properties, but principally because the same surface, when it becomes greasy, dirty, or scratched, has different properties. Many peculiarities of the deposition of dew on different objects are explained in detail in the popular work by Charles Tomlinson, entitled *The Dew-Drop and the Mist* (London, 1860). Moreover, the case of the natural deposition of dew on the grass and other plants very near the surface of the ground is not at all parallel to that where it is deposited upon metal plates or other bodies used as drosometers, partly because of the location, partly because of the difference in the substances, and largely because of the influence of slight local currents of air.

DROSTE-HÜLSHOFF, drō'stē-huls'hōf, ANNETTE ELIZABETH, BARONESS VON (1797–1848). A distinguished German lyric poet. She was born in the family castle of Hülshoff, near Münster, passed her life largely in seclusion, and died in the castle of Meersburg, on Lake Constance. Her *Gedichte* (1837; new ed., 1895), not numerous, are excellent in technique and gracefully sweet in character, particularly in their pictures of nature. In lyric and narrative forms they are well-nigh equally successful. Her poems appeal to the refined and thoughtful rather than to the ordinary reader. She is related artistically to Möricke, but she is more virile. Selections from them find place in most general collections of German verse. The posthumously printed *Das geistliche Jahr* (1852; new ed., 1883) consists largely of religious poems. She was an ardent Catholic. Her collected works, including the *Letzte Gaben* (1860), in which her splendid prose tale *Die Judenbuche* was printed, appeared in 3 vols. in 1878–79. Consult Schücking, *Annette von Droste-Hülshoff* (Hanover, 1871), and Busse, *Annette von Droste-Hülshoff* (Bielefeld, 1903).

DROUAIS, drō'ā'. A French family of artists.—HUBERT (1699–1767) was best known as a miniature painter. He was born at La Roche and studied at Rouen and under De Troy in Paris. His miniatures are principally in private collections, but there are two portraits by him in the Louvre—one of the painter Christophe, and the other of the sculptor Robert le Lorrain. He assisted Nattier and Van Loo in the execution of costumes and accessories, and was appointed court painter in 1744.—His son and pupil, FRANÇOIS HUBERT (1727–75), the most important member of the family, studied also under Van Loo, Natoire, and Boucher. It was the fashion to be painted by François at the time of Louis XV, and he has left many portraits, especially of women and

children, charmingly executed in the graceful, delicate, and rather weak style of the age. Among those who sat for him were Madame de Pompadour, Madame du Barry (as a muse, a huntress, and as Flora), Marie Antoinette as Hebe, and Mademoiselle Helvétius (Morgan collection, Metropolitan Museum, New York). There are also four portraits in the Louvre and many in private collections. François Drouais was court painter and counselor of the Academy. The most characteristic of his pictures is "A Child Playing with a Cat" (1765).—GERMAIN JEAN (1763–88) was the son of François. He was born in Paris and studied under his father, Frenet, and David, whose favorite pupil he was. In 1784 he won the Roman prize with his picture "Christ and the Canaanite Woman" (Louvre) and went with David to Rome, but he died there three years later. "Marius at Minturnas" (Louvre) and the "Dying Gladiator" (Rouen Museum), both painted during his stay in Rome, reveal Germain Jean as a beginner of much promise. He painted in the style of David, but with more sentiment. Consult Gabillot, "Les trois Drouais," in *Gazette des Beaux-Arts* (Paris, 1905–06).

DROUET, drōō'ā, JEAN BAPTISTE, COUNT D'ERLON (1765–1844). A marshal of France. He was born July 29, 1765, at Rheims, and entered the army as a private in 1782, took part in the campaigns of 1793–96, and became aid-de-camp to General Lefèvre. He distinguished himself during the sieges of Valenciennes, Le Quesnoy, and Condé, and in 1797, under Hoche, forced the surrender of the fortress of Ehrenbreitstein. His important services caused his rapid promotion, and he became brigadier general in 1799. Made a general of division in 1800, he took an active part in the campaign of 1805–07, distinguished himself at Jena and being wounded.

His conduct won him the Grand Cross of the Legion of Honor and the title of Comte d'Erlon. He took a prominent part in the Peninsular War, and fought bravely against Wellington in 1814. After the fall of Napoleon he was given command of the Sixteenth Division, but was shortly afterward arrested on the charge of conspiring against Louis XVIII. He managed to escape upon the approach of Napoleon, and, putting himself at the head of the troops, he seized the citadel and held it for the Emperor, who made him a peer of France. In the Waterloo campaign Drouet commanded the First Army Corps, but, misunderstanding the Emperor's orders, wasted valuable time in a fruitless march between Ligny and Quatre-Bras. After the capitulation of Paris he fled to Bavaria, where he resided until 1825, when he returned to France. He received, in 1830, the command of the Twelfth Military District, with headquarters at Nantes, where he put down the Legitimist rising in La Vendée and arrested the Duchesse de Berry. During 1831–35 he held the important office of Governor-General of Algeria and in 1843 was elevated to the rank of marshal. He died Jan. 25, 1844. Consult *Notice sur la vie militaire du maréchal Drouet, écrite par lui-même* (Paris, 1844), and Sloane, *Life of Napoleon* (New York, 1896).

DROUOT, drōō'ō, ANTOINE, COUNT (1774–1847). A French general, born at Nancy. He fought at Fleurus (1794) and Hohenlinden (1800) and greatly distinguished himself by his skill and valor at Wagram. On the retreat from Moscow he displayed extraordinary energy

and fertility of resource. One of his most brilliant exploits was performed at Hanau, where his desperate assault on the Bavarian army enabled the French to make good their retreat to the Rhine. He accompanied Napoleon to Elba as Governor of the island and subsequently fought at Waterloo. He enjoyed wide renown as an artilleryman, and his sound judgment secured for him the title of "Sage of the Grand Army."

DROUYN DE LHUYS, drōō'ān' de lwēs', EDOUARD (1805–81). A French diplomatist and politician. He was born in Paris, Nov. 19, 1805, and received a thorough classical and legal education at the Lycée Louis-le-Grand and the Ecole de Droit. In 1831 he was attached to the Embassy at Madrid. As chargé d'affaires at The Hague (1833–36), and thereafter as First Secretary of the Embassy at Madrid, he showed his diplomatic ability. In 1840 he was placed at the head of the Bureau de Commerce, under the Minister of Foreign Affairs, and in 1842 was elected deputy from Melun; but, having voted against the government, he was deprived of his administrative office by M. Guizot in 1845. He thereupon became a bitter opponent of the statesman and signed the act of accusation of the Guizot ministry drawn up by Odilon Barrot, Feb. 22, 1848. After the overthrow of Louis Philippe he was elected representative to the Constituent Assembly from the Department of Seine-et-Marne and became president of the Committee on Foreign Affairs. In the first cabinet formed by Louis Napoleon, after his election to the presidency in December, 1848, Drouyn de Lhuys became Minister of Foreign Affairs. In 1849 he went to London for a short time as Ambassador, and early in 1851 again became Minister of Foreign Affairs. After the coup d'état of Dec. 2, 1851, he became one of the vice presidents of the Senate, and in July, 1852, he was for the third time made Minister of Foreign Affairs. During this time he directed the negotiations relative to French participation in the Crimean War. Disappointed at the issue of the Vienna conferences in 1855, he resigned his office. In 1862 he was recalled, but resigned in 1866. On the fall of the Empire he fled to Jersey, but after a year returned to France and lived in retirement until his death, March 1, 1881. He was the author of a work entitled *Les neutres pendant la guerre d'Orient* (Paris, 1868). Consult Comte d'Harcourt, *Diplomatie et diplomates: les quatre ministères de M. Drouyn de Lhuys* (Paris, 1882); also his *Mémoires*, inserted in the collections of the French Academy of Moral and Political Sciences.

DROWN, THOMAS MESSINGER (1842–1904). An American chemist and metallurgist. After a course of study at the best scientific schools in the United States and at two European universities he was appointed instructor in metallurgy at Harvard and later professor of analytical chemistry at Lafayette College. From 1885 to 1895 he held the same chair at the Massachusetts Institute of Technology. In 1895 he became president of Lehigh University. He served as president of the American Institute of Mining Engineers in 1897.

DROWNING. See ASPHYXIA; RESUSCITATION.

DROWNING (from *drown*, from AS. *drucnian*, Icel. *drukna*, OHG. *trunkanēn*, *drunkanēn*. to drown, from AS. *druncen*, p.p. of *drincan*,

Icel. *drekkja*, OHG. *trinchān*, Ger. *trinken*, to drink). A form of capital punishment once common throughout Europe, but now obsolete among the nations of Christendom, though it is still practiced in Mohammedan countries and in the Far East. Tacitus, writing about the end of the first century, tells us that the Germans hanged their greater criminals, but that meaner offenders were plunged under hurdles into bogs and fens. By the law of the ancient Burgundians a faithless wife was condemned to be smothered in mud. The Anglo-Saxon codes ordered women convicted of theft to be drowned. The punishment was in such common use in the Middle Ages that grants of capital punishment ran *cum fossa et furca*, i.e., 'with pit and gallows.' The pit, ditch, or well was for drowning women; but the punishment was occasionally inflicted on men, perhaps because less cruel and revolting than other forms of capital punishment, as a matter of favor. Thus, in Scotland, in 1556, a man convicted of theft and sacrilege was sentenced to be drowned "by the Queen's special grace." So late as 1611 a man was drowned at Edinburgh for stealing a lamb. By that time the punishment of drowning had become obsolete in England. It survived in Scotland until 1685. The last execution by drowning in Switzerland took place in 1652, in Austria in 1776, in Iceland in 1777. It was abolished in Russia early in the 19th century. It has never been practiced in the United States. See CAPITAL PUNISHMENT; PUNISHMENT, and the authorities there referred to.

DROYSEN, *droi'zen*, JOHANN GUSTAV (1808-84). A German historian, born at Treptow. He studied in Berlin and became privatdocent there in 1833 and professor extraordinary in 1835. In 1840 he accepted a call to the University of Kiel, and thenceforth took a prominent part in the Schleswig-Holstein dispute with Denmark as an upholder of the German claims. Sent as a representative from Kiel to the Diet of Frankfurt, he was subsequently a member of the Frankfurt Parliament. In 1851 he was appointed professor of history at Jena, where he founded the historical seminar, and in 1859 was called again to Berlin, where he achieved a reputation as one of the greatest German historians of the century. He died in Berlin. Of his numerous works, the following are the most important: *Geschichte Alexanders des Grossen* (Berlin, 1833); *Geschichte des Hellenismus* (Hamburg, 1836-42); *Geschichte der preussischen Politik* (14 vols., Leipzig, 1855-86); *Grundzüge der Historik* (Leipzig, 1876). For his life, consult, Duncker, *Johann Gustav Droysen* (Berlin, 1885), and a biographical sketch by Kruger in his *Outlines of the Principles of History*, trans. by E. B. Andrews (Boston, 1893).

DROZ, *drô*, FRANÇOIS XAVIER JOSEPH (1773-1850). A French moralist and historian. He served for some years in the army, but afterward was appointed to the chair of oratory at the Ecole Centrale de Besançon. He soon attracted attention as a writer on philosophical subjects and especially as the author of an *Essai sur l'art d'être heureux* (1801). His *Philosophie morale* (1823) gave him a place in the Academy. His greatest work is *L'Histoire du règne de Louis XVI pendant les années où l'on pouvait prévoir et diriger la révolution française* (3 vols., 1839-42). His other works include: *Sur le droit politique* (1802); *Appli-*

cation de la morale à la politique (1825); *Economie politique* (1829).

DROZ, GUSTAV (1832-95). A minor French novelist and humorist, who catches the tone of the society of the Second Empire, toying with amiable vices, as the eighteenth century did with the pastoral virtues. His best novel is *Autour d'une source* (1869). His most successful and characteristic book, *Monsieur, Madame et Bébé* (1866), was the first to attract notice.

DROZ, NUMA (1844-99). A Swiss statesman, born at La Chaux-de-Fonds. He worked as an engraver, educated himself to be a school teacher, and in 1864 became editor of the radical journal *National Suisse*. In 1868 he was chosen a member of the Council of Neuchâtel, and in 1871 he conducted the religious and educational interests of the canton. In 1875 he became a member of the Federal Council and Minister of the Department of the Interior in 1875 and took the portfolio of Commerce and Agriculture in 1879. He was elected President of the Swiss Confederation in 1881 and again in 1887. Upon the establishment of the Bureau of International Railroad Transportation he was appointed its director (1893). His publications include: *L'Instruction civique* (2d ed., 1886); *Essais économiques* (1895); *Etudes et portraits politiques* (1895).

DROZ, PIERRE JACQUET (1721-90). A Swiss mechanic. He was born at La Chaux-de-Fonds and became famous as the improver of the mechanism of the watch and the inventor of a music box which reproduced the tones of various instruments, of an "automatic writer," operated by an internal mechanism, and of various other unique devices. One of his most important inventions was a self-adjusting pendulum.

DRUDE, *drö'de*, KARL GEORG OSKAR (1852-). A German botanist, born in Brunswick. From 1870 to 1874 he studied at Brunswick and Göttingen, and in 1879 he became professor of botany at the Polytechnical School, Dresden, and director of the botanical garden. In addition to the monograph published in collaboration with A. Engler under the title *Die Vegetation der Erde* (Leipzig, 1896 et seq.), his publications include: *Die Florenreiche der Erde* (1884); *Handbuch der Pflanzengeographie* (1890); *Deutschlands Pflanzengeographie*, vol. i (1895); *Der hercynische Florenbezirk* (1902); *Die Oekologie der Pflanzen* (1913); and valuable contributions to the publications of Martius and Berghaus.

DRUENTIA. The Roman name of the river now known as the Durance (q.v.).

DRUG (Fr. *drogue*, from Dutch *droog*, dry; being formerly supposed to dry and cleanse the body). Any substance, whether of animal, mineral, or vegetable origin, especially in its crude or commercial form, that is used as a medicine or in the preparation and composition of medicines.

DRUG ADDICTIONS. The principal drugs resulting in formation of habits are opium and its products (morphine, heroin, codeine, and others), cocaine, cannabis indica, alcohol, and tobacco.

The opium habit has long been practiced in the Far East and did not become popular in Europe and other western countries until some time after 1845, when the practice of injecting drugs through the hypodermic needle was introduced. Morphia was the drug used, and for a time the vice was extremely prevalent. Accord-

ing to Jouet and Zambaco, the habit became almost a fashion among the ladies of Paris and Constantinople, and hypodermic syringes of fanciful design and costly ornamentation were used and even given as presents. There were said to be 40,000 morphinomaniacs in Paris in 1883 and 100,000 in 1893, but since then the habit has greatly decreased. Extravagant figures have been quoted as to the prevalence of the morphine habit in the United States, but these are largely a matter of speculation. For the symptoms and effects of this addiction, see OPIUM.

The cocaine habit is of more recent growth. This drug was introduced into medicine 30 years ago, and its abuse has become a serious problem in Europe and America, partly through carelessness in prescribing solutions as nasal sprays, but principally from the introduction of it into patent medicines, catarrh snuffs, tonic wines, and the like. Various coca wines, vaunted as nerve tonics, serve merely as vehicles for cocaine. The cocaine habit is the most demoralizing and rapidly cultivated addiction known, since the effects of the drug wear off quickly and repeated doses are required. It is largely used by the criminal class; it seems to have a particularly debasing effect upon the mind and morals as well as the physique of the habitué, and it brings about rapidly a state of profound mental and moral degradation. Among the first effects are sleeplessness and loss of appetite, conditions which in themselves suffice to undermine the constitution. Soon there follow other manifestations: headache, lack of muscular control, symptoms of intestinal autointoxication, and later still delusions and hallucinations, which merge into insanity, with a tendency towards suicide. The habit is difficult to break, and comparatively few addicts ever fully recover. In South America the use of cocaine among the Indians has existed from time immemorial. Among them the habit takes the form of leaf chewing, a little alkali being mixed with the leaves. Overindulgence among these people, however, is comparatively rare.

Tea, coffee, cocoa, kola, maté, and guarana together form a group of products, widely used on account of certain stimulating principles, viz., caffeine, theobromine, theophyllin. These bodies are chemically distinct from cocaine, but as poisons they resemble it very closely. They are taken to overcome fatigue and to stimulate the cerebral functions. Prolonged abuse of the group establishes, no doubt, a certain degree of tolerance, but they all have a cumulative tendency. Tea tasters, e.g., are said to suffer from headache, noises in the ears, vertigo, sleeplessness, and impaired digestion. The excessive use of tea and coffee is known to be responsible for certain nervous disturbances, the principal features of which are instability and irritability, accompanied by sleeplessness and dyspepsia.

The effects of the moderate and excessive use of tobacco have long been a subject of debate. It is certain, however, that tobacco, while varying greatly in its action in different individuals, results in an increase in blood pressure and is therefore a factor in the production of arteriosclerosis. The heart is apt to be irregular, and poisoning of the optic nerve is occasionally observed. For further discussion of the addiction, see TOBACCO.

Chloral hydrate, paraldehyde, veronal, and

similar hypnotics are substances whose introduction as soporifics to replace opium resulted in the formation of habits in a great number of people. The ultimate effects, although somewhat slow in making themselves apparent, are not unlike those of cocaine. The addicts are, in the first place, apt to be neurotic, and any habit speedily fastens itself upon them. After a time the sleeplessness becomes worse, larger doses are required, and the patient becomes anæmic, weak, anxious, restless, and the heart action feeble and irregular. There is the usual deterioration in moral fibre, and the end is likely to be delusional insanity. Still another group of pain relievers may be mentioned. These belong to the same class as acetanilid and antipyrin and are represented by a host of popular headache remedies. Addiction to them causes a gradual decline in the general health, while the condition for which the remedy was taken becomes more pronounced. These drugs are nerve poisons, and their prolonged use induces a high degree of anæmia, cardiac weakness, abolition of the will power, and degeneration of the heart muscle. A description of the alcohol habit will be found under ALCOHOLISM and of cannabis indica addiction under HASHEESH. Consult: Sainsbury, *Drugs and the Drug Habit* (New York, 1909); C. A. McBride, *Modern Treatment of Alcoholism and Drug Narcotism* (ib., 1910); G. E. Pettey, *Narcotic Drug Diseases and Allied Ailments* (Philadelphia, 1913).

DRUGGER, ABEL. A gullible tobacconist in Jonson's *Alchemist*. The part was a favorite rôle of Garrick.

DRUGGET (Fr. *drouget*, of unknown etymology). A common felt or other coarse woollen fabric, often printed on one side and chiefly used for covering carpets or as a substitute for a carpet.

DRUGGISTS. See CHEMISTS AND DRUGGISTS.

DRUID (Lat. *druida*, Gk. *δρυῖδης*, *dryidēs*, from OIr. *drui*, nom. pl. *druid*, Gael. *draoi*, connected with OIr. *dair*, *daur*, oak, Gk. *δρῦς*, *drys*, tree, OChurch Slav. *drŭva*, Skt. *dāru*, wood). One of the fraternity of priests, religious teachers, and judges who ruled over the Celtic inhabitants of ancient Gaul, Britain, and Ireland. The institution of druidism was probably common to all Celtic nations, but we have detailed accounts of the form only under which it existed in Gaul. Cæsar gives the following description of the character and functions of the Druids: "They attend to divine worship, perform public and private sacrifices, and expound matters of religion. A great number of youths are gathered round them for the sake of education, and they enjoy the highest honor in that nation. Nearly all public and private quarrels come under their jurisdiction; and when any crime has been committed, as when a murder has been perpetrated, or when a controversy arises about a legacy or about landmarks, they are the judges too. They fix rewards and punishments; and should any one, whether a private individual or a public officer, disobey their decrees, then they exclude him from the sacrifices. This is with them the severest punishment. The persons who are thus laid under interdict are regarded as impious and wicked people; everybody recoils from them and shuns their society and conversation, lest he should be injured by associating with them. They cannot obtain legal redress when they ask for it, nor are they admitted to

any honorable office. . . . At a certain time of the year the Druids assemble in the territory of the Carnutes, which is believed to be the centre of all Gaul, in a sacred place. To that spot are gathered from everywhere all persons that have quarrels, and they abide by their judgments and decrees. It is believed that this custom was invented in Britannia and thence transplanted into Gaul. Even nowadays those who wish to become more intimately acquainted with the institution generally go to Britannia for instruction's sake.

"The Druids take no part in warfare; nor do they pay any taxes, like the rest of the people; they are exempt from military service and from all public burdens. Attracted by such rewards, many come to be instructed of their own choice, while others are sent by their parents. They are reported to learn in the school a great number of verses, so that some remain there 20 years. They think it an unhallowed thing to commit their lore to writing, though in the other public and private affairs of life they frequently make use of the Greek alphabet. . . . Beyond all things they are desirous to inspire a belief that men's souls do not perish, but transmigrate after death from one individual to another; and they hold that people are thereby most strongly urged to bravery, as the fear of death is thus destroyed."

This powerful priesthood did all they could to uphold the national cause against the Roman conquerors and urged the people to rebellion. The emperors Tiberius and Claudius found it necessary to interdict formally the practice of druidical rites, which seem, however, to have continued down to the extinction of paganism. Besides being priests and teachers of religion, the Druids appear to have been adepts in the magic arts and were versed in the mysterious powers of animals and plants. The oak tree was especially sacred among the Druids, and they frequently performed their rites in oak groves. They also had a special reverence for mistletoe when growing on an oak. According to the elder Pliny, a Druid, clothed in white, mounted the tree and with a knife of gold cut the mistletoe, which was received by another standing on the ground, on a spotless cloth. The same author gives a curious account of the "serpent's egg" worn as a distinguishing badge by the Druids. It was formed, he says, by the poisonous spittle of a great many serpents twined together. Gathered at moonlight, and afterward worn in the bosom, it was a mighty talisman. All these particulars refer properly to the Druids of Gaul, but the druidism of Britain was probably essentially the same.

In all the countries anciently inhabited by Celts there are found rude structures of stone, one of the most common forms of which is the so-called *dolmen* (q.v.). The older archæologists assumed that these were druidical altars, but there is no proof that such was their purpose or origin. Similar structures are found in Scandinavia and Germany, and to assume in all these countries the presence of Celts seems too hazardous. The same doubts prevail as to the supposed druidical temples of Avebury, of Carnac in Brittany, and of Stonehenge (q.v.). Consult: Cæsar, *De Bello Gallico*, vi, 13, 14; Ramsay, *Foundations of England*, vol. i (London, 1894); D'Arbois Jubainville, *Introduction à l'étude de la littérature celtique*, (Paris, 1883); id., *Les Druides et les dieux celtiques à forme d'ani-*

maux (ib., 1906); Bonwick, *Irish Druids and Old Irish Religions* (London, 1894); Rhys, *Lectures on the Origin and Growth of Religion as Illustrated by Celtic Heathendom* (ib., 1888). See CELTIC PEOPLES.

DRUIDS, ORDER OF. A secret organization for purposes of mutual aid and protection, established in London in 1781, introduced in the city of New York in 1833 and in Germany in 1872. In England a number of independent lodges sprang from the parent organization; in the United States the order assumed a more national character, the first grand grove (the name "lodge" was discontinued) having been established in 1849. The society included, in 1914, 18 grand groves and 542 subgroves, with a total membership of 29,525; in the same year it had paid out in benefits \$7,833,226. Many of the members of the organization are German or of German descent.

DRUM (Dutch *trom*, Ger. *Trommel*, dial. *dromm*, from OHG. *trumba*, *trumpa*, trumpet, It. *tromba*, Fr. *trompe*, Eng. *trump*; connected ultimately with Lat. *triumphus*, triumph, Gk. *θρῠαμβος*, *thriambos*, Bacchic procession). A musical instrument of percussion, consisting of a cylinder of wood or brass over one or both ends of which a membrane is stretched tightly by means of wooden hoops. There are four kinds of drums—the side drum, only differing from the snare drum (q.v.) in the absence of gut strings across its under side, the bass drum (q.v.), and the kettledrum (q.v.). With the exception of the last, drums cannot be perfectly tuned and hence are of use only to mark or vary the rhythm. Drums of various forms were early used in Egypt and India. An Egyptian instrument corresponding to the modern African tomtom can be traced back to about 1600 B.C. The *tympanum* of the Greeks and Romans resembled a small modern kettledrum, though it could not be tuned to any exact pitch. From India the use of drums spread westward, being introduced into Europe either by the Moors or through the Crusades. See MUSICAL INSTRUMENTS.

DRUM, IN ARCHITECTURE. 1. Any one of the superposed cylindrical blocks of which a nonmonolithic column is composed. (See COLUMN.) 2. The circular or polygonal structure on which domes are often carried, raising them high above the surrounding structure. The drum was developed from the crown of buttressed windows of Hagia Sophia and similar Byzantine domes. It occurs chiefly in late Byzantine and in Renaissance domes, as in St. Peter's at Rome, but is seen also in many Mohammedan domes. See DOME; MOHAMMEDAN ART.

DRUM, or DRUMFISH (so called from the drumming noise). Any of several fishes of the family *Sciaenidæ*, most of the species of which make a noise under water variously called croaking, drumming, snoring, grunting, etc., but which most resembles the roll of a muffled or distant drum. This noise is commonly thought to be produced by the transfer of air to different compartments of the air bladder. The fishermen frequently attribute it to the rubbing together of the broad pharyngeal teeth, which are arranged like a cobblestone pavement and are often preserved as a seashore curiosity. These remarks more particularly apply to the salt-water drum of the Atlantic coast of the United States (*Pogonias chromis*), which has been known to exceed 100 pounds in weight, but ordi-

narly is less than 50. It is a heavily built fish, with poor flesh, large scales arranged in diagonal rows, and a large number of short barbels hanging from the lower jaw. In search of the mollusks upon which it mainly feeds it frequents bays and shallow coastal waters, and may often be heard at night "drumming" steadily for a long time beneath an anchored boat. It is a great pest to the oyster planters about New York, destroying annually a vast amount of cultivated oysters, the fish crushing into fragments hundreds more than it eats. (Consult, on this point, Ingersoll, "The Oyster Industry," in *United States Tenth Census Report*, Washington, 1881.) This species ranges on the east coast south to Uruguay. The southern variety (*Pogonias curbina*) is known by the Brazilians as *curbina*, meaning "croaker." The fresh-water or river drum (*Aplidnotus grunniens*), also known as thumpumper, sheepshead, and croaker, is a kindred fish, common in the lakes and streams of the Mississippi valley. In the North it is not much valued, but in the South it ranks high as a food fish. Other species of drum are the red drum (*Sciaenops ocellatus*) of the South Atlantic and Gulf States, and the black drums of the genus *Sciana*, mostly of the Old World. Most of the species afford good sport with the line.

DRUMCLOG, drüm-klög' (Gael., ridge of stone). A tract of moorland in Lanarkshire, Scotland, famous as the place where 200 Camerons defeated Claverhouse on June 11, 1679 (Map: Scotland, D 4). An obelisk commemorates the victory. The battle is graphically described in Scott's *Old Mortality*.

DRUMLIN (from Ir., Gael., *druim*, drum, ridge). A smoothly arched oval hill rarely more than 150 feet high or more than $\frac{1}{2}$ mile long, usually occurring on the flat lowlands, and looking somewhat like a sand dune, but made of coarser materials and covered with thin soil and vegetation. Drumlins are composed of till, as it is called in Scotland, or the hardpan or boulder clay of northern New England, that has been heaped up by the pressure of overlying glaciers. They have steep convex sides and are elongated in the direction of an ice flow, i.e., usually from north to south. Drumlins occur in all glaciated districts, and their existence in New England, New York, and the lake region of North America indicates that all of that country has been once covered with glaciers, or rather with a single continuous glacial covering. Drumlins are found over all that portion of North America, Europe, and Asia that lies north of the terminal moraine of the continental glacier. See GLACIER; GLACIAL PERIOD.

DRUM MAJOR. The noncommissioned officer in charge of a drum corps or band. In the United States army he is appointed by the regimental commanders upon the recommendation of regimental adjutants. He ranks with first sergeants, receiving pay at the rate of from \$36 to \$60 per month according to length of service. Under the supervision of the regimental adjutant he has charge of the interior discipline and administration of the band. At all formations of the band he leads and controls its movements. The chief musician, pay from \$75 to \$99, has charge of the musical instruction of the band as distinguished from its military instruction. In the English service, since 1878, the drum major has been called the sergeant drummer.

DRUMMER. In the United States army there is no official grade of drummer. However, a drum and fife corps is sometimes organized by the regimental commander. For this purpose he usually details the two trumpeters of each troop, the three musicians of each battery or the two musicians of each company, and other privates, to take the necessary instruction and drill under the drum major. Trumpeters and musicians have the rank and pay of privates. In the United States and British army they act as *drummers* in the daily routine of barrack and camp life, and *drummers* by bugle or drum the various duties of the day.

DRUMMOND, GEORGE. See PERTH, EARL OF. **DRUMMOND, SIR GORDON** (1772-1854). A British soldier, born in Quebec. He became an ensign in the Royal Scots in 1789, was rapidly promoted, and in 1794 attained the rank of lieutenant colonel of the King's Liverpool Regiment, which he commanded in several campaigns on the Continent, particularly distinguishing himself at the battle of Nimeguen. He served in the Egyptian campaigns of 1800-01, commanded a division in Jamaica from 1805 to 1807, and in 1810, with the rank of lieutenant general, was second in command to Sir George Prevost, commander of the forces in Canada. He took part in the American War of 1812, commanding the British at the indecisive battle of Lundy's Lane, or Bridgewater, on July 25, 1814, and remained in Canada as commander in chief of the British forces after the close of the war, until 1816. He was promoted to the rank of general in 1825 and made G.C.B. in 1837.

DRUMMOND, HENRY (1851-97). An English author and minister of the Free church, born in Stirling, Scotland. From the high school of Stirling and a boarding school in Crieff he passed to the University of Edinburgh (1866). Four years later he began his preparation for the ministry at New College, Edinburgh. Stirred by the preaching of Moody, he engaged in active mission work (1873-75); in 1877 he was appointed lecturer on natural science in the Free Church of Glasgow, and in 1884 became professor of natural science.

He now began missionary work among college students with very great success. The "Free Church" movement he initiated spread throughout the English-speaking world, and he was called to America and Australia. In the interest of science he also made expeditions to the Rocky Mountains and to South Africa. The aim of Drummond was to reconcile science and religion. To this end he wrote *Natural Law in the Spiritual World* (1883) and *The Ascent of Man* (1894). He also published *Tropical Africa* (1888); *Travel Sketches* (1890); and other books and addresses, among which is *The Greatest Thing in the World* (1890). Drummond's books were widely read and made a deep impression, at least upon amateurs in science. For biography, consult George Adam Smith, *Life of Drummond* (1902), and lives by Lennox (New York, 1901) and Simpson (ib., 1901).

DRUMMOND, JAMES (1835-). An English Unitarian theologian. He was born in Dublin, the son of a clergyman, William Hamilton Drummond, who translated Lucretius. He graduated at Trinity College, Dublin, in 1855; studied theology at Manchester New College, in 1859-69 was minister of the Cross Street Unitarian Chapel, Manchester, and then became professor of theology in Manchester New College, where he succeeded James Martineau as princi-

pal in 1885. He retired from this post in 1906. His principal works, apart from New Testament commentaries, deal with the period immediately before the New Testament and its influence on apostolic thought. They include: *The Jewish Messiah* (1877); *Introduction to Theology* (1884); *Philo-Judeus* (1888), probably the most valuable book in English on Jewish Alexandrian philosophy; commentaries on Galatians (1893) and Thessalonians (1899); *Via, Veritas, Vita* (1894, Hibbert Lectures); *Some Thoughts on Christology* (1902); *Life and Letters of James Martineau* (1902, with Upton); *The Character and Authorship of the Fourth Gospel* (1904); *Johannine Thoughts* (1909); *Paul: His Life and Teaching* (1911).

DRUMMOND, THOMAS (1797-1840). A Scottish engineer. He was born at Edinburgh, was educated at the Royal Military Academy, Woolwich, and in 1815 entered the Royal Engineers. In 1820 he was engaged by Colonel Colby to assist in the trigonometrical survey of the United Kingdom. The incandescence of lime having been brought under his notice at a lecture on chemistry, the idea occurred to him that it might be advantageously used on the survey to render distant objects visible. He accordingly made experiments, which resulted in the introduction of the limelight (Drummond light). A heliostat (q.v.) of his invention was also used extensively. He was head of the commission appointed to readjust the borough boundaries under the provisions of the Reform Bill of 1832 and in 1835 became Undersecretary of State for Ireland.

DRUMMOND, WILLIAM (1585-1649). A Scottish poet, descended from a very ancient and noble family and born at the family seat, Hawthornden, near Edinburgh. He was educated at the high school of Edinburgh and at the university of that city, where he took his degree of A.M. in 1605. During 1607-08 he was on the Continent, attending law lectures in Bourges and Paris. He returned in 1609 and in the following year went to Hawthornden, which, according to the learned Ruddiman, "was a sweet and solitary seat, and very fit and proper for the muses," and there spent his life in his favorite literary pursuits. Drummond enjoyed the friendship of many literary men, and the record of a famous visit of Ben Jonson to Hawthornden, in the winter of 1618-19, has been preserved in Drummond's *Notes of Ben Jonson's Conversation with William Drummond*. His verse, written in the standard English dialect, comprises an elegy on the death of Prince Henry, son of James I, entitled *Tears on the Death of Meliades* (1613); *Poems* (1616), in which are some of his choicest pieces; and *Fourth Feasting* (1617), in honor of James I's visit to Scotland. Drummond had a rare command over difficult metres, and many of his sonnets and madrigals are very beautiful. A *Cypress Grove* (1623), an essay on death, is a remarkable piece of prose. He also wrote political tracts, and a history of Scotland from 1424 to 1542. His *Poems*, ed. with memoir, by W. C. Ward, were published in 2 vols. (London, 1894; New York, 1905). For his *Life*, consult Masson (ib., 1873). A later edition of his poems is *Poetical Works*, ed. L. E. Kastner (2 vols., University of Manchester, and New York, 1913).

DRUMMOND, SIR WILLIAM (1770-1828). An English diplomat and writer. In 1796 and 1801 he was a member of Parliament and at

different times was sent on diplomatic missions to Naples and Constantinople. His writings include: *A Review of the Government of Sparta and Athens* (1795); *Origines* (1824-29); and the *Edipus Judaicus* (1811), notable for its ingenuity in explaining Old Testament stories as astronomical allegories.

DRUMMOND, WILLIAM HENRY (1854-1907). A Canadian poet. He was born in County Leitrim, Ireland, but in early youth came to Canada. He was educated at the English high school and McGill University, Montreal, and in 1884 . . . in medicine at the University of Bishc . . . Lennoxville, P. Q., in which he afterward became professor of medical jurisprudence. He began professional practice in a little community made up of Indians, half-breeds, French *habitants*, Scotch-Irish Canadians, and English, and affording unusual opportunities for observing character. He soon removed to Montreal, where he continued to practice until his death. Fond of sport, he learned wood lore and enjoyed forest and camp life, chiefly with the French-Canadians, whom he afterward portrayed. In his poetry the *habitant* was made to speak in broken English so naturally that the insight, pathos, and humor are heightened rather than obscured by the oddities of dialect and idiom. His Irish-dialect and English poems are not equal in merit to his poems of the *habitant*. His publications are: *The Habitant and Other French-Canadian Poems* (1897); *Phil-o-rum's Canoe and Madeleine Vercheres* (1898); *Johnnie Courteau and Other Poems* (1901); *The Voyageur and Other Poems* (1905); *The Great Fight* (1908). *The Poetical Works of William Henry Drummond*, with an introduction by Louis Fréchette and an appreciation by Neil Munro, was published in 1912. Consult "English-Canadian Literature," in *Canada and its Provinces*, vol. vi (Toronto, 1914).

DRUMMOND ISLAND. An island forming a part of Chippewa Co., Mich. (Map: Michigan, K 3). It lies in Lake Huron and is the most westerly of the Manitoulin group, being about 30 miles east of Mackinaw. It is 20 miles long and 10 miles wide at the widest place.

DRUMMOND LIGHT, CALCIUM LIGHT, or LIMELIGHT. The intense brilliant light that is produced when an oxyhydrogen flame is directed against lime. The light was invented by Capt. Thomas Drummond (q.v.). In the production of the light minute portions of the lime become volatilized by the intense heat. The cylinder of lime must therefore be kept slowly rotating by means of clockwork, so that a new surface may be continually presented to the flame. Ordinary illuminating gas is often substituted for the hydrogen, the oxygen being supplied to the gas flame in a highly compressed state. Magnesia, zirconia, and other earths have the similar property of . . . when heated. The Drummond light, and the light obtained by strongly heating other metallic oxides than that of calcium, are employed in magic lanterns, in photography, etc. The Drummond light has now been superseded by the electric arc light.

DRUMMONSSEE MOOR. See CULLODEN.

DRUMONT, dru'môn', EDOUARD ADOLPHE (1844- . . .). A French anti-Semitic agitator and journalist, born at Paris. He was at first in the government service, but later became a contributor to the press and was the author of a

number of miscellaneous works, of which *Mon vieux Paris* (1879) was crowned by the Academy. In 1886 he began a violent campaign against the Jews in his book *La France juive devant l'opinion*. This was followed by *La fin d'un monde* (1888); *Dernière bataille* (1890); *Testament d'un antisémite* (1891); *Secret de fourmies* (1892); *De l'or de la boue du sang* (1896), dealing with the Panama scandals; *Les Juifs et l'affaire Dreyfus* (1899); *Vieux portraits, vieux cadres* (1900). In 1892 he founded the *Libre Parole* as an organ for his views. From 1898 to 1902 he represented Algiers in the Chamber of Deputies. Consult Stéphane Arnoulin, *M. Edouard Drumont et les Jésuites* (Paris, 1902).

DRUNKENNESS (AS. *druncness*, from *druncen*, p.p. of *drincan*, Icel. *drekka*, Goth. *drigkan*, OHG, *trinchān*, Ger. *trinken*, to drink). The mental and physical condition resulting from excessive drinking of intoxicating liquors. Its effect upon the contractual capacity of its victim is the same as that of insanity, though in Lord Coke's time intoxication was no ground for avoiding a contract. "As for a drunkard," he declares, "who is *voluntarius dæmon*, he hath no privilege thereby." It is now settled, in accordance with the dictates of good sense and common justice, that a contract made by a person so destitute of reason as not to know the consequences of his agreement, though his incompetency be produced by voluntary drunkenness, is voidable at his option.

Drunkenness can rarely be pleaded as a defense in an action of tort (q.v.). In the United States there is judicial authority, however, for the admission of this plea when the tort complained of involves a special intent on the part of the defendant. Civil misconduct of that sort does not often come before the courts, and in the great majority of tort actions, such as those for assault and battery, for defamation, for negligence, and for trespass to land, the drunkenness of the wrongdoer has been held not a legitimate defense.

In criminal law it is well settled that drunkenness is not a justification or excuse for crime. Still, when an essential ingredient of the crime with which a prisoner is charged is the doing an act with a specific intent—as in entering a house by night with intent to commit larceny, or in assaulting a female with intent forcibly to ravish—the drunkenness of the actor may be taken into account by the jury in determining whether he acted with that specific intent. If the jury believe that he was so drunk as to be incapable of forming such specific intent, they are bound to acquit him of the offense charged.

In itself drunkenness is not a legal offense, though drunken conduct in public may be a nuisance and is often made a statutory offense, punishable by arrest, fine, and imprisonment.

When habitual, drunkenness may also render the drunkard liable to a judicial inquisition for the appointment of a committee or trustees to assume the guardianship of him and his property. The proceeding is properly instituted by the wife or children or next of kin of the alleged drunkard on the ground of his incompetence to control his acts or look after his property or business affairs. See *INSANITY*; *LUNACY*. Consult: Kent, *Commentaries on American Law*; Pollock, *Principles of Contract in Law and in Equity* (2d Amer. ed., G. H. Wald,

ed., Cincinnati, 1885); Bishop, *Commentaries on Non-Contract Law* (Boston, 1889); Woodruff, *Cases on Domestic Relations and the Law of Persons*, part v (New York, 1897). See *ALCOHOL*, *PHARMACOLOGY*, ETC.; *ALCOHOLISM*; *DIPSOMANIA*; *INTOXICATION*; *TEMPERANCE*.

DRUNKEN PARLIAMENT, THE. A name given to the Scottish Parliament of 1661, the members of which were accused of constant drunkenness. By one act it annulled the acts of the parliaments preceding it for 28 years and brought about the upheaval of the whole Scotch church system.

DRUPE (Fr., from Lat. *drupa*, Gk. *δρύππα*, *dryppa*, overripe olive, from *δρυπετής*, *drypepēs*, ripened on the tree, from *δρῦς*, *drys*, tree + *πέτραιν*, *peptein*, to cook, or *δρυπετής*, *drypetēs*, fallen from the tree, from *δρῦς*, *drys*, tree + *πίπτειν*, *piptein*, to fall). A stone fruit, in which the ovary wall, in forming the pericarp, develops an outer fleshy layer and an inner stony or bony layer, as in the peach, plum, cherry, etc. See *FRUIT*. For illustration, see Plate of *DRUPES*.

DRUPELET. A small drupe, as the individual "grains" of a blackberry, raspberry, etc. See *FRUIT*.

DRURY, DRU (1725-1803). An English silversmith and engraver, born in London. His *Illustrations of the Natural History of Insects* (2 vols., 1773-82) is a work containing much valuable material and illustrated with a large number of beautiful figures. Besides this, he wrote *Illustrations of Natural History* (1770-82) and several other works and gathered a remarkably fine collection of insects.

DRURY LANE. A street in London, leading from the Strand towards Oxford Street and the British Museum; named after Sir William Drury, whose house during the reign of Henry VIII stood where the entrance from the Strand is now. It was a fashionable quarter under the Stuarts, but in Queen Anne's time its respectability had begun to decline.

DRURY LANE THEATRE. A famous London playhouse. It was first built, under royal patent, in 1663, by Thomas Killigrew (q.v.), whose company was known as the King's Company, in distinction from the Duke's Company of Davenant (q.v.). The house was originally called the Theatre Royal. Burned in 1672, it was rebuilt in 1674 from designs by Sir Christopher Wren. In the years that followed rivalry between the two companies was so ill-sustained that in 1682 they were united. A dozen years later, however, Betterton (q.v.) and others of the company made their well-known secession to Lincoln's Inn Fields, and in 1709 continued bad rivalry brought the theatre to a close. Colley Cibber and his associates renewed its prosperity, and Garrick's management, which followed (1746-76), was perhaps the most famous in its history, with "Peg" Woffington and "Kitty" Clive as leading stars. In 1791 the old building made way for a new structure which was opened three years later and managed by Sheridan. In 1809 this again was destroyed by fire, and in 1812 the present house was opened. The acting of Kean gave it prosperity for a time, but since his day Drury Lane and its managers have suffered numerous vicissitudes. In recent years it has been devoted largely to spectacular pieces and English opera. Consult Stirling, *Old Drury Lane* (London, 1881), and Doran, *In and About Drury Lane* (ib., 1881).

DRURY'S BLUFF, BATTLE OF. See BER-MUDA HUNDRED.

DRUSES, drōō'ez. A people of mixed origin, who inhabit a district in Syria . . . southern portion of the Lebanon . . . ern slope of Anti-Lebanon as well as a large portion of the region of the Hauran. In the first-mentioned district they hold exclusive possession of about 40 towns and villages and divide the possession of about 200 more with the Maronites (q.v.), while 80 villages in other parts of Anti-Lebanon are peopled by them. They number about 100,000 or 150,000 and are probably derived from Kurdish, Persian, and Arab stock. Their religion is fundamentally Mohammedan, but of a peculiar type, which they adhere to with stern fanaticism. Early in the eleventh century Hakem, the Fatimite Caliph of Egypt, a cruel tyrant hated by his people, caused the incarnation of God in himself to be publicly preached in Cairo by his confessor, Darasi, who thereby brought upon himself the active hatred of the people. He escaped to the Lebanon, where he was received by the mountaineers and taught his new religion. From him the name "Druses" is probably derived. It was, however, by Hamze, a Persian disciple of Hakem, that the faith was given the form in which the Druses hold it. The Druses have maintained their religious and political independence for nearly nine centuries. Their faith mingles the teachings of the Mosaic law, the Christian Gospels, the Koran, and the Sufi allegories. Their seven cardinal principles are: (1) veracity in dealings with each other; (2) mutual protection and resistance; (3) renunciation of other religions; (4) belief in the divine incarnation in Hakem; (5) contentment with the works of God; (6) submission to His will; (7) separation from those in error and from demons. They believe in one God who has revealed Himself 10 times upon earth as mortal man, the incarnation in Hakem being the tenth and last. They believe in the transmigration of souls, with constant advancement and final purification. Their teachings enjoin abstinence from wine and tobacco, from profanity and obscenity. They are divided into the Akals, or initiated, and the Djahils, the ignorant. The latter are free from all religious duties. Between 1840 and 1860 there was bitter strife between the Druses and their immediate neighbors, the Maronite Christians. Owing to the shocking barbarities perpetrated by the Druses in 1860, the European Powers undertook to intervene in defense of the Christians. A French army was dispatched to Syria in August, and a commission of the Powers was appointed to investigate the facts. The Druses escaped into the Hauran desert, and it was found that Turks and Damascene fanatics were really responsible for stirring up the strife in which the Maronites had acted with a vindictiveness equal to that of the Druses. Punishment was meted out to the Mohammedans, who were principally responsible, and among others Achmet Pasha, the Governor of Damascus, was shot. In June, 1861, the troops returned to France, and the commissioners drew up a scheme of Government for the Lebanon. It provided for a Christian governor, appointed by the Porte, and the division of the region into seven districts, under chiefs of the religion prevailing in each. Fuad Pasha, an Armenian Christian, was the first Governor, and the district chiefs

included four Maronites, one Druse, one orthodox Greek, and one separatist Greek. The constitution did not satisfy the Maronites, whose revolt, under Joseph Karan, kept the Lebanon in a very unsettled state till 1867. During this period the Governor had to restrain the Druses from attacking the Maronite villages. They had no superior educational establishment until Fuad Pasha founded and endowed one at Abeih. Polygamy is unknown among them. They possess an extensive theological literature. They have with incredible toil carried the soil of the valleys up and along the hillsides, which are laid out in terraces, planted with mulberry, olive, and vine. Their chief trade is the manufacture of silk. Corn is raised, though in very small quantities. Deir-el-Kamar is the principal town. Consult: Silvestre de Sacy, *Exposé de la religion des Druses* (1838); Earl of Carnarvon, *Druses of the Lebanon* (London, 1860); Churchill, *Ten Years' Residence in Mount Lebanon* (ib., 1853); id., *The Druses and Maronites under Turkish Rule from 1840 to 1860* (ib., 1862); Guys, *La nation druse* (Paris, 1864); id., *La théogonie des Druses* (ib., 1863); Oliphant, *Land of Gilead* (London, 1880); id., *Haifa* (ib., 1887); Ewing, *Arab and Druze at Home* (ib., 1907).

DRUSILLA, LIVIA. See LIVIA DRUSILLA.

DRUSILLA. 1. The daughter of Germanicus and Agrippina, born in 15 A.D. She lived with her brother Caligula as his mistress until her death in 38. 2. The daughter of Herod Agrippa I, King of Judea. She married Azizus, King of Emesa, but forsook him and married Antonius Felix, who became governor of Judaea, and before whom St. Paul appeared at Cæsarea.

DRUSIUS, drōō'si-ūs, JOHANNES (JAN VAN DER DRIESCHE) (1550-1616). A Flemish-Protestant scholar, born at Oudenarde. He studied at Ghent, Louvain, and Cambridge, and in 1572 was appointed professor of Oriental languages at Oxford. In 1577 he obtained a similar chair at Leyden and from 1585 until his death held the professorship of Hebrew at the University of Franeker, where he had students from England, and the Protestant countries of the Continent. He was employed by the States-General to annotate the Old Testament, and his edition is to be found in the *Critici Sacri* (London, 1660; Amsterdam, 1698). His complete works were published in 10 volumes (1622-36). Consult Nicéron, *Mémoires des hommes*, vol. xxii (Paris, 1733), and Diestel, *Geschichte des alten Testaments in der christlichen Kirche* (Jena, 1869).

DRUSUS. The name of a distinguished family of the gens Livia, which contributed a large proportion of eminent men to the Roman commonwealth. The most conspicuous of the Drusi were: 1. M. LIVIUS DRUSUS, tribune of the people in 122 B.C., who upheld the cause of the Senate and the nobles against his democratic colleague, Gaius Gracchus. 2. His son, who bore the same name as himself, and kept Rome in perpetual turmoil and disorder from 100 B.C. till his death in 91. Though identified by birth and sympathy with the patricians, Drusus, to win the people, revived some of the most liberal measures of the Gracchi and carried agrarian and frumentarian laws. During the latter years of his life he contrived to gather into his own hands the threads of the various political movements which resulted in the Social War; he even promised the Latins Roman citi-

zenship. This roused the Senate to abrogate his laws, and civil strife seemed certain, till one night Drusus was stabbed. 3. The most illustrious of the Drusi was Nero Claudius Drusus, commonly called Drusus Senior. He was son of Tiberius Claudius Nero and Livia Drusilla and so was the stepson of the Emperor Augustus and younger brother of the Emperor Tiberius. He was born in 38 B.C. As he grew up he developed splendid personal qualities as well as the highest capacity for civil and military affairs. He began his public career in 19 B.C. and signalized himself when only 23 years old by his defeat of the Rhetians and other Alpine tribes which were disturbing the north of Italy. In 13 B.C. he was sent into Gaul, then in revolt, and, after crushing the rebels there, pushed across the Rhine in pursuit of their German allies. In this campaign he subdued the Sigambri and the Frisii and forced his way to the German Ocean, being the first Roman general to do so. From this time he strove to establish the Roman supremacy in Germany, partly by conquest and partly by the execution of great military works. Among these latter may be mentioned the canal joining the Rhine with the German Ocean, two bridges over the Rhine itself, and the embankments of the Vahalis (Waal). In 11 B.C. he conquered the Usipetes, the Cherusci, and the Suevi; in the following year he subdued the Chatti and the Nervii; he was the work of subjugation in 9 B.C. when a fall from his horse cut short his brilliant career in his thirtieth year. For his exploits in Germany Drusus was rewarded with the title of Germanicus, a surname which passed over to his celebrated son. (See GERMANICUS.) Another of his sons was afterward the Emperor Claudius.

DRUSUS, ARCH OF. The name given to a travertine arch coated with marble over the Appian Way in Rome, said to have been erected in honor of Claudius Drusus, but in reality an arch of the aqueduct built by Caracalla to supply his baths. Of the arch really built in honor of Drusus, perhaps near the point where the Via Latina branches from the Via Appia, no trace has been found.

DRUSUS CÆSAR, usually called DRUSUS JUNIOR, to distinguish him from Nero Claudius Drusus (see DRUSUS, 3) (?-23 A.D.). The son of the Emperor Tiberius by his first wife, Vipsania Agrippina. He was made quæstor in 10 A.D. and consul in 15 A.D. but degraded the office by his excesses, and his father sent him with the army to Illyria. In 22 A.D. he received the *tribunicia potestas* and was looked upon as heir to the throne. Sejanus, wishing to supplant Drusus, deliberately won the affections of Livia, Drusus's wife, and together they caused the death of Drusus by poison.

DRYADS (Lat. *dryas*, from Gk. *δρύας*, *dryas*, wood-nymph, from *δρῦς*, *drys*, tree, oak), or HAMADRYADS. The nymphs of the trees and the forests. According to the popular belief each tree had its own dryad, who came into life with it, tenderly watched its growth, and died when it fell. The dryad was sometimes conceived as dwelling in her tree, sometimes as merely living near it. The name "dryad" is also employed in a general sense for nymphs who merely dwell in the forest without association with particular trees. See NYMPHS.

DRYANDER, dry-ân-dēr. ERNST (1843-). A German Protestant theologian, born

in Halle. He was educated at the universities of Halle and Tübingen from 1879 to 1882 was pastor of the Evangelical congregation in Bonn, and in the latter year became pastor of the church of the Holy Trinity in Berlin, where he quickly became known for his pulpit eloquence. In 1898 he became court preacher, in 1901 a life member of the Upper House of Prussia, and in 1907 vice president of the Evangelical Oberkirchenrat. His publications include *Predigten über das christliche Leben* (3d ed., 1890) and *Der erste Brief Johannis in Predigten ausgelegt* (1898).

DRYANDER, FRANZ. See ENZINAS.

DRYASDUST, REV. DR. The imaginary person who signs the introductory epistles to several of Scott's novels and the conclusion to *Redgauntlet*. The name is used as a synonym for a prosy writer and has become famous through Carlyle.

DRYBURGH ABBEY. An impressive ruin near Melrose, Scotland, which contains the tomb of Sir Walter Scott. It is an admirable example of the Norman and early English styles of architecture.

DRYDEN. A village in Tompkins Co., N. Y., 36 miles south-southeast of Auburn, on the Lehigh Valley Railroad (Map: New York, D 6). It has large woolen mills and granite and marble works. Sulphur springs and a healthful and attractive situation make the village a popular resort. The Southworth Library is a public institution. The water works and electric-light plant are owned by the municipality. Dryden Township includes the village of Freeville, where is located the George Junior Republic (q.v.). Pop., 1900, 699; 1910, 709.

DRYDEN, JOHN (1631-1700). An English dramatist, poet, and critic, born at Aldwinkle, a village of Northamptonshire, Aug. 9, 1631. His father, Erasmus Dryden, was the third son of Sir Erasmus Dryden, or Driden, Baronet. Dryden received the rudiments of his education at Tichmarsh and was a King's scholar at Westminster School, under Dr. Busby. In 1649 he contributed an elegy to the *Tears of the Muses*, a collection of 33 poems on the death of Henry, Lord Hastings. The poem, written in the "metaphysical" style, was a poor performance even for a schoolboy. In May, 1650, he entered Trinity College, Cambridge, and in October was elected to a scholarship from his old school. Later in the same year he prefixed a few commendatory verses to the *Sion and Parnassus* of John Hoddesdon; he graduated B.A. in January, 1654. His father died in 1654 and left him a small estate estimated at £60 a year, of which sum his mother had life interest in a third. It is thought that he remained at Cambridge till 1657 and then took up his residence in London. Like the rest of his family, he was an adherent of Cromwell. In 1658 he published his first poem of importance, entitled *Heroic Stanzas to the Memory of Oliver Cromwell*. The restoration of Charles II he celebrated in two poems, *Astræa Redux* (1660) and *Panegyric on the Coronation* (1661). There is no good reason for doubting the sincerity of Dryden in these poems. He had admired Cromwell rather than Puritanism, and he was glad to see the old order restored. His social position, rather than his scientific attainments, was honored by election as fellow of the Royal Society (1662). He had become the friend of Sir Robert Howard, himself a poet, and on

Dec. 1, 1663, he married Sir Robert's sister, the Lady Elizabeth Howard, a woman whose previous reputation was not above the reach of scandal and with whom Dryden was unhappy. He had already begun his career as dramatist, and his first play, the *Wild Gallant*, was performed without success at the King's Theatre in February, 1663. During the next 20 years he produced many successful plays, although the comedies are coarse and the tragedies stiff. The best is *All for Love* (1678), founded on Shakespeare's *Anthony and Cleopatra*, written in blank verse, while his other tragedies are in heroic couplets. In the meantime he had produced *Annus Mirabilis* (1667), the subject of which is the Dutch war and the fire in London of the year before. In 1668 he published his great *Essay on Dramatic Poesy*, which established his reputation as one of the greatest English critics, but which led to a quarrel with his brother-in-law over the comparative merits of rhyme and blank verse. Though they both had written "heroic plays," i.e., melodramatic tragedies in rhymed couplet, Howard saw fit to defend blank verse against Dryden's preference for rhyme. Later Dryden himself went back to blank verse, when under the spell of Shakespeare. In 1670 he was appointed poet laureate and historiographer with a salary of £200 a year. This double post he held till the revolution in 1688. In 1671 the Duke of Buckingham produced a famous attack on the English heroic drama, of which Dryden was the head. This satirical piece was entitled *The Rehearsal*, and when it was brought on the stage the town was amused to find all the artificialities of this kind of writing brought together and exaggerated and charged to Dryden. Although personally satirized, Dryden endured his castigation in silence and, awaiting his opportunity, incidentally revenged himself on the witty and profligate Duke in *Absalom and Achitophel* (first part, 1681). This magnificent satire arose out of the political commotions of the times and is an elaborate defense of the King against the Whig party. Charles II is David; Monmouth, Absalom; Cromwell, Saul; Buckingham, Zimri; and Shaftesbury, Achitophel. Its success was amazing. Immediately after its publication Shaftesbury was arrested on a charge of high treason, but the London grand jury, on November 24, threw out the indictment. His release was celebrated by a medal, with his portrait on one side and on the other a representation of the city of London. In March, 1682, Dryden published his satire *The Medal*. One of the numerous replies to this satire was written by a former friend, Thomas Shadwell, who attacked Dryden in a savage poem, *The Medal of John Bayes*. Dryden took a crushing revenge in his immortal *MacFlecknoe*, published October, 1682. In November Nahum Tate brought out a continuation of *Absalom and Achitophel*, into which Dryden inserted a passage containing magnificently savage portraits of Elkanah Settle, another of his enemies, and of Shadwell. His critics now crushed, Dryden became the undisputed king and lawgiver of English literature in his day. In 1682 he stated and maintained the doctrines of the Church of England in a poem entitled *Religio Laici*.

After the death of Charles II Dryden became a convert to the Roman Catholic faith. This event was announced by the publication of *The*

Hind and Panther (1687). For this change of faith he has been much abused. Macaulay calls him "an illustrious renegade." Others strenuously defend his sincerity. At the revolution he was deprived of his laureateship, and, somewhat straitened in circumstances, he turned again to the stage. His translation of Vergil, begun in 1694, was published in 1697. In 1687 he had written his beautiful *Song for St. Cecilia's Day*, and exactly 10 years later he treated the subject with still greater success in his noble ode, *Alexander's Feast*. Both poems were written for a London musical society and were set to music. In 1699 he published, under the title of *Fables*, versions of Ovid, Boccaccio, and Chaucer, to which was added one of his great prefaces. He died May 1, 1700, and on the 13th was buried in Westminster Abbey.

Although the great bulk of Dryden's work consists of plays which are for the most part devoid of character, feeble in sentiment, false to nature, and exaggerated in expression, he must always remain a prominent figure in English literature. His *Satires* are masterpieces. In these he is masculine and natural, and his versification flows on, broad, deep, and majestic. Nor is it only as a poet that he excels; his prefaces and *Essay on Dramatic Poesy* prove him to be a master of "that other harmony of prose." Dryden's plays were published separately during his lifetime. His poems were collected in 1 vol. (1701), in 2 vols. (1742), and in 4 vols. (1760). His prose was collected in 4 vols. by Malone (1800). His *Complete Works* were edited with a *Life*, by Walter Scott in 18 vols. (Edinburgh, 1808; reprinted 1821, and revised by Saintsbury, 1882-93); the *Poetical Works* were edited, with a *Life*, by Christie (London, 1870); and a critical edition of *Essays*, ed. by Ker, was published in Oxford in 1900. Consult also: Garnett, *Age of Dryden* (London, 1895); and for his biography, Saintsbury (ib., 1881); Beljame, *Le public et les hommes de lettres en Angleterre (1660-1744)* (Paris, 1881); Collins, *Essays and Studies* (London, 1895); Ward, *History of English Dramatic Literature*, (ib., 1899); Chase, *The English Heroic Play* (New York, 1903); Frye, *Dryden and the Critical Canons of the Eighteenth Century* (Lincoln, Neb., 1907); Sargant, *Poems* (Oxford, 1911); Noyes, *Poetical Works* (Boston, 1909). For a complete bibliography, consult the *Cambridge History of English Literature*, vol. viii (New York, 1912).

DRYDEN, JOHN FAIRCHILD (1839-1911). An American insurance official, born near Farmington, Me. After attending Yale College he entered business as a life-insurance agent. In 1873 he founded the Widows' and Orphans' Friendly Society, the successor of which (1875), the Prudential Life Insurance Company, became one of the greatest corporations of its kind in the United States. Dryden was a presidential elector in 1896 and 1900, and, to fill an unexpired term, he was United States Senator from 1902 to 1907. As a candidate in the latter year for election for a full term, he met so much opposition that he withdrew in favor of John Kean. He was one of the organizers of the Public Service Corporation of New Jersey and was interested in other financial and industrial concerns. He published *Addresses and Papers on Life Insurance and Other Subjects* (1909) and also other lectures and speeches.

DRY DOCK. See Dock.

DRY FARMING is the generally profitable production of useful crops without irrigation under a rainfall of 20 inches or less. This is accomplished through suitable methods of soil tillage and farm management, but the controlling factor is the amount of precipitation. The chances of success decrease as the rainfall diminishes. The underlying principle is the storage and conservation of moisture in the soil in quantities sufficient to produce profitable crop growth and the selection or introduction of drought-resistant crops. Dry farming does not mean growing crops on dry soils, but under conditions of a limited or more unfavorably distributed rainfall. The problems which enter into the practice are the storage and retention of moisture in the soil at all times, the water requirements of plants as a basis of crop selection, soil management, and methods of crop utilization and marketing. With the proper attention to all these factors profitable crops are practically assured with a rainfall of over 15 inches, but with a precipitation of 10 to 15 inches crop culture becomes more difficult and the work more exacting, while with less than 10 inches a paying return is exceptional. In the United States these different degrees of precipitation exist quite generally in the region west of a line running through the Dakotas, Nebraska, Kansas, Oklahoma, and Texas, and extending to and including eastern Washington and Oregon and eastern and southern California. In general, regions having less than an equivalent of 10 inches of rainfall are regarded as arid and those with a precipitation of 10 to 20 inches as semiarid. Over one-half of the United States requires either irrigation or the use of dry-farming methods to make agriculture profitable and the same is true of regions of Europe, mainly in Russia, and of Asia, Africa, South America, and Australia; in fact more than one-half of the earth's surface is arid or semiarid. Deep and uniform soils are best adapted to dry farming. A hardpan too near the surface interferes with root penetration and thus limits the utilization of soil moisture by the crop, while gravelly layers facilitate leaching and destroy capillarity. The soil management in dry farming is based on the principle of storing the largest possible amount of the annual precipitation in the soil for the use of the crop. The purpose of it is to reduce the run off to a minimum and to increase the absorption and retentive powers of the soil to a maximum. By deep and proper cultivation the upper foot of soil is rendered absorptive, enabling water to sink into the lower layers and to be held there for future use by keeping the surface in suitable condition. A good subsoil has a great water-storing capacity. Deep plowing is practiced so that water may be taken up readily and in large quantities and be prevented from rapidly evaporating under the actions of sunshine and wind. It is essential that the land be plowed immediately after the crop has been harvested and that at all times a loose dry soil mulch be kept at the surface to check evaporation. This soil mulch is generally most effective when it is 8 to 10 inches deep, quite uniform in texture, and not too finely pulverized. Cultivation is given at frequent intervals and is especially important early in spring. Clean summer fallowing is practiced every other year with a low rainfall and every third or fourth year under a higher

rainfall. Weeds draw upon the soil moisture supply, and the land is therefore kept free from them at all times. The crops best adapted to dry farming and those generally grown are wheat, oats, barley, rye, which is one of the surest, emmer, corn, potatoes, sorghums, such as Kafir corn, milo maize, durra, feterita, etc., alfalfa, field pea, and field bean. Among fruits the date and the olive are essentially dry-farm crops. By selection and adaptation of varieties to dry-farm conditions much greater success has been secured and the dry-farming area extended. Sowing is done when conditions for germination are most favorable, which for many crops is in the fall, and in early spring when moisture is likely to be most abundant. It is aimed to place the seed just deep enough to insure germination, and for this purpose the use of the drill is always considered better than broadcasting. Thin seeding is generally practiced, the seed used being only about one-half the quantity used in humid regions. Wheat, oats, and barley are sown at the rate of about three pecks per acre, and corn at the usual distances is planted only two in a hill. After seeding and planting the land is worked with the disk harrow, corrugated roller, spike-tooth harrow, weeder, or cultivator to prevent the formation of a surface crust. Dry farming, as a rule, produces crops low in water content and in carbohydrates, and high in protein. The fertility of the soil, which is a regulator of transpiration, is maintained to a certain extent by growing leguminous crops in rotation wherever this is possible and by turning under all crop residues. The small grains are usually harvested with a header, and the straw is plowed down. To facilitate decay and improve the condition of the soil for the retention of moisture, the crops and crop residues to be turned under are cut up by means of the disk harrow before plowing is begun. Sometimes the land is plowed 7 to 10 inches deep and is then subsoiled to increase the moisture reservoir, but the practice is expensive and does not always prove profitable. Dairying, in connection with the silo to preserve green feed which cannot be matured on account of drought, is proving successful in many sections, in some cases pits being used in place of above-ground silos to save expense. In addition to the different kinds of plows the implements largely used in dry farming are spike-tooth, spring-tooth, and disk harrows, narrow-toothed and narrow-shoveled cultivators, the subsurface packer used in packing loose soils such as those containing crop substance turned under, and the disk drill and seeder, or the drill seeder with press wheels. The Campbell system of soil culture brought into prominence from 1890 to 1900 was essentially a system of dry farming. The first dry-farming congress was held in Denver in 1907. This itinerant congress, now an annual and international affair, is generally held in connection with an agricultural exposition mainly with reference to dry-farming products. Consult: Widdsoe, *Dry Farming: A System of Agriculture for Countries under a Low Rainfall* (New York, 1911); Shaw, *Dry Land Farming* (St. Paul, 1912); Olin, *American Irrigation Farming* (Chicago, 1913). Consult also the publications of the United States Department of Agriculture and of the Departments of Agriculture of the Western States.

DRY-FLY FISHING. See FLY CASTING.

DRY GANGRENE, gān-grēn'. See ERGOTISM.

DRYING MACHINES. Devices for the speedy drying of textile materials. The machine commonly used for removing the excess of liquor from textile materials consists of two drums, or cylinders, open at the top; the inner one, into which the goods are packed, is perforated at its sides and made to revolve with great velocity. The use of the outer cylinder is merely to catch the drops of water thrown out by centrifugal force as the wet material or clothes rapidly revolve. These drying machines are commonly called extractors or centrifugal wringers. A simpler drying machine, called a wringer, consists of two rollers mounted parallel, and one above the other, with an adjustment to vary the distances between them. One end of the article to be dried is inserted between the rollers, which are then brought as close as possible together, and one roller is turned by a handle; the other, being free to revolve, turns also as the clothes pass between them—the moisture in this case being extracted by pressure as in the common process of wringing. The drying is not, however, quite completed by such machines, and the remaining moisture is removed by open-air or hot-chamber drying or by passing over heated cylinders or coils of steam pipes. In the various branches of textile and paper manufacture drying apparatus adapted to the particular industry is used, and is described in the separate articles on these subjects.

DRYING OILS. See OILS.

DRY MURRAIN, mūr'rēn. See TEXAS FEVER.

DRYNESS. A technical term in painting, used to indicate a style in which the drawing is hard, angular, and formal, and the color deficient in harmony and mellowness. It is opposed to a free method of drawing and to the unctuous manipulation of pigment. In sculpture it indicates a lack of softness and roundness of form. Dryness is common to the primitive schools, which lacked command of the technique of painting; but it is found also in more developed art, being sometimes the result of personal temperament. Among modern painters certain of the Pre-Raphaelites have been criticized for this defect.

DRYOPE, dri'ō-pē (Lat., from Gk. Δρυόπη). The daughter of Dryops, a king of Thessaly who was the reputed ancestor of a people called Dryopes. She was the mother of a son by Apollo, who visited her in the form of a tortoise. She was finally carried off by the wood nymphs and changed into a poplar.

DRYOPHIS. See LANGAHA; WHIP SNAKE.

DRY PILE. A voltaic pile or battery consisting of a number of disks of paper covered with zinc foil on one side and gilt or black oxide of manganese on the other. Various modifications of the above form are also known by the same name. Following the invention of Volta (see VOLTAIC CELL OR BATTERY), Behrens in 1805 constructed a pile in which paper was used instead of moistened cloth, in consequence of which it was called a dry pile. The term "dry pile" is really a misnomer, as the pile is inactive unless the paper contains a certain amount of moisture. Behrens's construction was modified and improved by Zamboni, by whose name the dry pile is often known. In this apparatus the pile was made of so-called silver

paper and paper which had been rubbed with hydrogen peroxide. The couples were made of small disks of the paper so treated, placed together with their coated sides outward, and these were piled up to the number of 1000 or more, each couple or pair facing in the same direction. The entire pile was then firmly pressed into a glass tube varnished with shellac, and finally covered on the ends with brass caps. These have been made with as many as 20,000 pair of disks and capable of charging a thin Leyden jar of 350 square centimeters surface in 10 minutes to such an extent that its discharge melted 2.5 centimeters of platinum wire of .05 millimeter diameter.

The dry pile was employed by Behrens and Bohnenberger in the construction of a very delicate gold-leaf electroscope, commonly known by the latter's name. For this purpose the dry pile was constructed in two columns connected together below, so that the poles were at the upper ends. Between these poles a single gold leaf was suspended. As one pole is positive and the other negative, a very slight charge given to the gold leaf is sufficient to make it move towards one of the poles of the dry pile. The dry pile has also been applied to the construction of a "perpetual motion" electric pendulum, in which case it is divided into two columns, in the same way as in the electroscope just described, and between them a very light pendulum rod is balanced on knife-edges. On the upper end of the rod is a light metal ring which oscillates between the two poles. The pendulum inclines first to one side, and the ring touches one pole, at which it is charged. The pendulum is then repelled and carries it to the opposite pole, where the charge is neutralized, and it receives a charge of the opposite polarity, which reverses its motion. This action is repeated indefinitely. Such a pendulum has been in continuous motion in the University of Innsbruck since 1823. The period of its oscillation varies slightly with the humidity of the atmosphere. The energy expended is exceedingly minute, as no pile can generate a sensible current except by a corresponding consumption of its materials in the shape of chemical action. See VOLTAIC CELL OR BATTERY.

DRY POINT. The art and process of engraving on metal with a needle or other sharp point which scratches the surface. It differs essentially from line engraving in that none of the metal is cut away, and from etching in the absence of acid which corrodes the metal. In its effect dry point resembles etching rather than engraving because it is executed with the needle, not with the burin (q.v.), and in that the line is freely drawn. The scratches of the point cause a certain turning up or accumulation of the metal, in rough projection, beside the scratch or cut; this roughness is called the bur, and as it holds much more ink in printing than would a simple scratch of the needle, it gives a rich and soft effect of line, which is the peculiar charm of this medium. Dry-point work is often used to finish a plate which has been previously etched, because it can be applied without recoating the plate with the varnish and then using the mordant. (See ETCHING.) The term "dry point" is also applied to the needle with which the plate is scratched. It is nothing more than a rather heavy etching needle ground more obliquely and is sometimes pointed with a diamond, whence also the name "diamond dry-point

etching" as applied to the process. Consult the bibliography of ETCHING.

DRY ROT. A popular name for the decay of timber after it has been seasoned. Dry rot is usually slow in its action, though under some circumstances it may be rapid and destructive, ruining edifices and causing serious accidents. Dry rot is commonly caused by the fungus *Merulius lachrymans*. Somewhat similar effects are due to certain species of *Polyporus* and other fungi. The disease is quite common in timber that is exposed to moisture, as the ends of joists set in damp walls, wainscoting about sinks, etc. The timber is ultimately reduced to powder within a thin surface shell of sound wood. Although called dry rot, moisture is essential for the development of the fungus that causes it. The spores germinate and send their mycelium through the wood in all directions, attacking and destroying the wood fibres. At first the fungus appears as a thin white film which gradually thickens at the centre and changes to a rusty-brown color. A kind of timber known as red striped shows the beginning of dry rot. Perfectly sound timber may become infested by spores gaining entrance through cracks in the ends of logs, which, when wet, swell up. If the moisture be constant, the dry rot continues to grow, weakening the timber. The timber may dry out without destroying the fungus, which recommences developing when moisture is again present. The use of some kinds of sound-deadening material, such as wet cement, coal ashes, etc., is very favorable to the development of dry rot. Only dry gravel or coarse sand should be used. Coal cinders, etc., are alkaline, and the spores of *Merulius lachrymans* can be germinated best in the presence of alkalies. Timber that is well seasoned and protected by paint will not be attacked by dry rot.

A number of fungi attack the wood of trees, causing what is often called dry rot. Most of these fungi belong to the class of toadstools and shelf fungi and sometimes are seriously destructive. This form of rot is caused on apple trees by *Polyporus hispidus*; on oak, alder, poplar, locust, and larch, by *Polyporus sulphureus*; on larch, Scotch and white pine, by *Polyporus schweinitzii*; on conifers, by *Fomes pinicola*; etc. *Dactylea quercina* is a common saprophyte upon oak stumps and oak trees. The mycelium of this species forms leathery mats and is believed to be parasitic. The decomposing oak wood assumes a grayish-brown color.

DRY STOVE. See GREENHOUSE.

DRY TORTU/GAS. A group of ten islets belonging to Monroe Co., Fla., and situated at the extreme west end of the Florida Keys in lat. 24° 37' N. (Map: United States, K 6). They are of coral formation, low, and are partially covered with mangrove bushes. Fort Jefferson, on one of them, was a penal station during the Civil War. With the permission of the United States Lighthouse Board the Carnegie Institution of Washington established in 1904 on Loggerhead Key, one of the islands, a marine biological laboratory, at which much important scientific work has been done, and in 1908 the United States government set aside the entire group as a Federal bird reservation.

DUAL (Lat. *dualis*). A technical term of grammar, used to denote that form of the noun, pronoun, adjective, or verb which refers exclusively to two persons or things. The dual number differs, therefore, from the singular number,

which relates to one alone, and from the plural number, which relates indefinitely to three or more. The dual is regularly found in Sanskrit and in the most ancient Greek; and in Latin it appears in the pronoun *ambo* (both) and in the numerals *duo* (two) and *octo* (eight, i.e., two sets of four). It is not generally found in the Teutonic languages; yet the Gothic has it in the verb, and the Anglo-Saxon shows traces of it in two pronominal forms. It occurs in the Semitic languages, e.g., the Arabic and the Hebrew, though only in the nouns.

DUAL CONTROL. See EGYPT.

DU'ALINE (from *dual*, Lat. *dualis*, relating to two). The name given by C. Dittmar to that form of dynamite consisting of cellulose, nitrocellulose, nitrostarch, nitromannite, and nitroglycerin mixed in different combinations to the strength desired (United States Patent 4 of Jan. 18, 1870). A preferred composition put on the market was nitroglycerin, 50 per cent; fine sawdust, 30 per cent; saltpetre, 20 per cent. See EXPLOSIVES.

DU'ALISM (Lat. *dualis*, relating to two). In philosophy, the theory that the universe is explicable only as a whole with two fundamentally different kinds of constituent elements. The ancient dualism of matter and form has in modern times been replaced by a dualism of mind and matter as two different kinds of substance. Among modern philosophers Descartes was the first to emphasize the radical difference between thinking substance (mind) and extended substance (matter). The difficulty suggested by this view was to explain how mind and matter interact as they apparently do in experience. This perplexity caused some of his followers to deny interaction and assert concomitance of variation under divine control (see OCCASIONALISM); it caused others to deny the truth of dualism (see MONISM; SPINOZA; LEIBNITZ). In our day the question has been under more or less constant debate, and no unanimity has been reached as to the relative truth of dualism and its rivals. Within recent years the interest awakened by scientific psychology has brought the problem more to the fore, but even in psychology there is no consensus on the subject. (See PARALLELISM.) While idealism was the regnant philosophy, dualism was of course officially discarded. The recent reaction against idealism has in certain quarters, however, brought about a revival of dualism. One of the most interesting defenses of dualism is made by Prof. William McDougall (q.v.), who maintains that there is good evidence, both psychological and biological, for the existence of souls directing physiological processes. His position is frankly animistic, and the essential notion underlying animism is "that all, or some, of those manifestations of life and mind which distinguish the living man from the corpse and from inorganic bodies are due to the operation within him of something which is of a nature different from that of the body, an animating principle generally, but not necessarily or always, conceived as an immaterial and individual being or soul." Driesch (q.v.) comes to a similar conclusion, calling his nonmechanical principle "entelechy." Bergson (q.v.) in his second great work, *Matter and Memory*, takes likewise a dualistic position, matter being what we perceive with our senses and having in itself the qualities that we perceive in it, such as color and resistance. Mind, on the other hand, re-

veals itself as memory, the faculty of storing up the past and utilizing it for modifying our present actions, which would otherwise be merely mechanical. However, in his more recent work, *Creative Evolution*, Bergson takes a more monistic view, regarding matter as vital impulse which has become arrested. Vital impulse, *l'élan vital*, is, "for want of a better name," called by him "consciousness in general," "which must be coextensive with universal life."

But not all recent reactions against idealism have resulted in dualism; or at least, if what results be called dualism, it is a dualism in many cases of function and not of ontological character. Thus, W. James (q.v.) and John Dewey (q.v.) maintain that there is no unalterable difference between the physical and the psychic. The same thing may be the one or the other according to the way in which it behaves in experience. James says that there is no difference in quality or substance between "mental knives," i.e., what would ordinarily be called imaginary knives, and physical knives. The difference is that while mental knives may or may not cut mental wood, physical knives will regularly cut physical wood. For Dewey anything is physical which is accepted without question and treated in our action as unquestionable; it is psychic when it becomes problematic and forms the point of departure for a process of testing. One of the merits claimed for such a functionalistic distinction is that it frees us from the necessity of raising the time-worn problem as to the way in which mind acts on body and body on mind.

It is impossible here to give more than the preceding illustrations of the vast variety of views current at present on the problem of dualism. With perhaps a few exceptions, e.g., McDougall, the belief in mind and matter as distinct substances is generally discarded. The older dualism of substance is giving way to newer distinctions, such as the functionalistic distinction made by James or Dewey, or to distinctions of character, or to monisms, whether idealistic, materialistic, or neutral. See IDEALISM; INSTRUMENTALISM; MONISM; MATERIALISM; PRAGMATISM; REALISM. Consult: McDougall, *Body and Mind* (New York, 1911); James, *Essays in Radical Empiricism* (ib., 1912); Dewey, *Studies in Logical Theory* (Chicago, 1903); Driesch, *Science and Philosophy of the Organism* (London, 1908-09); Bergson, *Matter and Memory* (Eng. trans., ib., 1911); *Creative Evolution* (Eng. trans., New York, 1911); Royce, *The World and the Individual* (ib., 1900-01); Ward, *Naturalism and Agnosticism* (ib., 1899); id., *The Realm of Ends* (ib., 1911).

DUALITY (Lat. *dualitas*, state of being two-fold, from *dualis*, relating to two). A principle of geometry by which one proposition is transformed into another through the interchange of a pair of elements; e.g., the proposition: If two triangles have two *sides* and the included *angle* of the one respectively equal to two *sides* and the included *angle* of the other, the triangles are congruent, may be transformed by the interchange of the words *sides* and *angles* into another familiar proposition: If two triangles have two *angles* and the included *side* of the one respectively equal to two *angles* and the included *side* of the other, the triangles are congruent. This principle is often called the principle of reciprocity and is extensively used in geometry. Although the reciprocal of a

valid proposition is not of itself necessarily valid, it often suggests new possible theorems for investigation. In plane geometry the dual elements most commonly ' , ' , ' , ' are:

point—line;

line—point;

angles of a triangle—

(opposite) sides of the triangle;

sides of a triangle—

(opposite) angles of the triangle;

pencil of lines—range of points;

range of points—pencil of lines.

Similarly there are dual propositions of solid geometry, as those formed by interchanging the words *straight line* and *plane*; e.g., two intersecting *straight lines* determine a *plane*; two intersecting *planes* determine a *straight line*. Such dual propositions also exist, one in plane geometry and the other in solid geometry, as when the terms *triangle* and *trihedral angle* are interchanged; e.g., one *side* of a *triangle* is less than the sum of the other two sides; one *face angle* of a *trihedral angle* is less than the sum of the other two face angles. The term *duality* appears in the projective geometry of Gergonne (1813), and the development of the "principle of duality" in another work by the same author (1826). This principle is a powerful agent of modern geometry, where the term is more strictly defined than above and where the theory is carefully developed, and it has been applied to various properties of curves.

DUANE, dū-ān', JAMES (1733-97). An American lawyer and jurist. He married into the Livingston family, studied law, and attained great prominence in his profession before the Revolution. In the heated political discussions preceding the war he opposed all radical measures, being ready to sacrifice much for the sake of peace. He was chosen a delegate to the first Continental Congress in 1774 and aroused violent opposition by his proposal for a recognition of the validity of the British Navigation Acts and his advocacy of Galloway's scheme for a union of all the Colonies under a chief magistrate appointed by the King. His distrust of a republican form of government led him vigorously to oppose the signing of the Declaration of Independence. He continued to hope for pacification until the last, but when the break came he threw in his lot with the Patriot party. He continued a member of the Continental Congress throughout the entire Revolutionary period, taking an active part in the debates. He was one of the authors of the first New York State constitution, was a member of the Committee of Safety in New York City in 1776-77, and after the evacuation of the city by the British in 1783 he was chosen the first mayor under the new charter, serving until 1789. In that year he was appointed by Washington to the office of United States District Judge for New York, which he held until 1794, rendering many decisions which were of considerable importance in the formative period of the country's existence. He was a member of the State Senate in 1782-85 and in 1789-90, and of the convention that adopted the Federal Constitution in 1788.

DUANE, JAMES CHATHAM (1824-97). An American military engineer, born in Schenectady, N. Y. He graduated at Union College in 1844 and at West Point in 1848; commanded the engineer company in the Utah expedition of 1858, and was instructor at West Point from

that year until 1861. In the Civil War he served with distinction as captain of engineers in the Peninsular campaign of 1862; was chief engineer of the Army of the Potomac in the battles of South Mountain and Antietam; was chief engineer of the Department of the South for a time in 1863; and from July, 1863, until the close of the war again served in the Army of the Potomac. He was brevetted brigadier general in 1865, was promoted lieutenant colonel in the regular army in 1867, had charge of the construction of the fort at Willets Point, N. Y., from 1865 to 1868, served as superintendent of fortifications on the Maine and New Hampshire coasts, and in 1886 became chief of engineers with the regular rank of brigadier general. He published a *Manual for Engineer Troops* (1862).

DUANE, WILLIAM (1760-1835). An American politician and journalist, born in northern New York near the banks of Lake Champlain. He was sent to Ireland in 1771 to be educated, learned the printer's trade, and in 1784 went to British India, where he made a fortune and established a newspaper called the *World* at Calcutta. In consequence of too free criticism of the government authorities there, Duane was kidnapped at the command of Sir John Shore, the Governor, and deported to England, while his property in India was confiscated. Duane's efforts to obtain relief, either from the East India Company or the British government, were unavailing, and he again entered the field of journalism, becoming editor of the *General Advertiser*, in London, a paper which later was merged in the *London Times*. In 1795 he returned to America, where he became associated with Benjamin Franklin Bache in Philadelphia in editing the *Aurora*, one of the strongest Republican organs in the country. Forming an alliance with Michael Leib and other radical Republicans, he dominated the party in Pennsylvania for several years. In the *Aurora*, following the journalistic methods introduced in America by Cobbett, he attacked his political and personal enemies bitterly and unsparingly, filling his columns with fierce invective, insinuations, and scandal of every sort. Not only were the Federalists the objects of his attacks, but, disappointed in not receiving from Jefferson rewards commensurate with what he conceived to be the value of his services to him, he set out to hamper the administration and to sow discord among its members. He attacked Gallatin constantly, attempting to arouse Jefferson's jealousy by declaring that he was seeking to become his successor in the presidency. In 1800 he was brought before the United States Senate on a charge of libel. He was arraigned, but refused to appear for trial or put in a defense, denying the Senate's jurisdiction. He was adjudged guilty of contempt, and his arrest ordered, but he was never arrested. In Pennsylvania politics he exerted great influence and originated the organization known as the "Friends of the People" in opposition to that wing of the party represented by Gallatin, Dallas, and McKean. In 1804 he pressed the wholesale impeachment of the State Supreme Court judges. The transfer of the seat of government to Washington decreased the importance of the *Aurora*, which grew more abusive as its influence grew less. In 1808, just before retiring,

Jefferson appointed Duane a lieutenant colonel in the army. He continued to edit the *Aurora* and attacked Madison in particular, who quieted him in 1813 by an appointment as adjutant general. He sold the *Aurora* in 1822 and after traveling in South America wrote *A Visit to Colombia in 1822-23* (1826). He also published: *The Mississippi Question* (1803); *Military Dictionary* (1810); *An Epitome of the Arts and Sciences* (1811); *Handbook for Riflemen* (1813); *Handbook for Infantry* (1813); *American Military Library* (1819).

DUANE, WILLIAM JOHN (1780-1865). An American lawyer and financier. He was born in Clonmel, Ireland, studied law, was admitted to the bar in 1815, and practiced his profession in Philadelphia. He obtained distinction as a lawyer and, becoming interested in education, served as a trustee and subsequently as a director of Girard College. In 1833 he was appointed Secretary of the Treasury by President Jackson, but was removed later in the year for refusing to withdraw the government deposits from the United States Bank without authority from Congress. He was the author of: *The Law of Nations Investigated* (1809); *Letters on Internal Improvements* (1811); *Narrative and Correspondence Concerning the Removal of the Deposits* (1838).

DUBAN, du'bän', FELIX LOUIS JACQUES (1797-1870). A French architect, born in Paris. A pupil of Debret at the Ecole des Beaux-Arts, he won the Grand Prix de Rome in 1823 and spent five years in Italy. Returning to Paris in 1828, he joined with Duc and Labrousse in the *Néo-grec* movement to reform architecture. His chief work was the reconstruction and extension of the Ecole des Beaux-Arts buildings, on which he labored from 1832 until his death. The library, Pompeian court, and museum of architectural casts are especially admired. Meanwhile he was restoring the Château de Blois, and carrying out extensive operations at Fontainebleau, Compiègne, and the Louvre. On the last, however, he was in 1853 superseded by Visconti (q.v.).

DU BARRY, du bá'ré', MARIE JEANNE BÉCU, COMTESSE (1743-93). The celebrated mistress of Louis XV. She was born Aug. 19, 1743, at Vaucouleurs, and was the natural daughter of a woman named Anne Bécu, who about the year 1749 returned to Paris with her two children, Jeanne and Claude, and married a domestic named Rançon. The beauty of little Jeanne won her many friends, chief of whom was the rich financier and philanthropist M. Billaud-Dumonceaux. Through him and the Abbé Arnaud she was admitted to the convent school of Sainte-Aurèle. There she remained for some seven or eight years, acquiring but little knowledge and enduring a great deal of irksome discipline. Emerging from the convent at the age of 15, Jeanne Bécu—or Jeanne Rançon, as she appears then to have been called—dwelt with her mother for a time and then became a lady's maid to Madame de la Garde and later a milliner in the house of a certain Sieur Labille, where she doubtless had many love affairs. She was at this time known as Mademoiselle Lange, but soon assumed the more aristocratic cognomen of Beauvarnier. In the midst of her gallantries Jeanne Bécu met the dissolute Comte Jean du Barry, known specifically as "the Roué," who made her his mistress and induced her to change her name to Vaubarnier or Vaubernier,

by which she is generally known with the subsequently added prefix Gomard. For four years she presided over the gaming rooms of her lover, until in the spring of 1768 she came in the path of Louis XV, who was immediately captivated by her charms and made her his mistress. To add a show of decency to the matter, a husband was found for her in the person of Comte Guillaume du Barry, the brother of Comte Jean. For five years the Du Barry ruled King and court. The Duc de Choiseul was her confidant and adviser, the Comte de Maupéou used her influence to dismiss and exile the Parlement in 1771, while the Abbé Ternay was suave and polite to her at all times. She was the patron of artists and men of letters, and during her reign she is estimated to have cost France 35,000,000 livres. She had numerous enemies, however, chief of whom was the Duc de Choiseul, Minister of Foreign Affairs, whose dismissal she brought about in 1770. The death of Louis XV caused her retirement from the court. Some time after the outbreak of the Revolution she went to London to see about the recovery of her jewels, which had been stolen. On her return Robespierre caused her to be arrested, July, 1793. In November she was tried before the Revolutionary Tribunal and accused of "having wasted the treasures of the state, of conspiracy against the Republic, and with having, in London, worn mourning for the late King." She was condemned to death and was sent to the guillotine, Dec. 7, 1793. Most of the accounts given of Madame du Barry are unreliable. She was the victim of much slander, and stories concerning her amours are rarely trustworthy. The *Mémoires* (6 vols., Paris, 1829-30; Eng. trans., 1830; 1896), published under her name, have no real value. Consult: Douglas, *Life and Times of Madame du Barry* (London, 1896); Lacretelle, *Histoire de France pendant le dix-huitième siècle* (Paris, 1830); Vatel, *Histoire de Madame du Barry, etc.* (Versailles, 1880); Goncourt, *La Du Barry* (Paris, 1880); Williams, *Madame du Barry* (New York, 1909).

DU BARTAS. See BARTAS.

DUBBS, JOSEPH HENRY (1838-1910). An American Reformed church clergyman, born at North Whitehall, Pa. He graduated at Franklin and Marshall College, Lancaster, Pa., in 1856, and at Mercersburg Theological Seminary in 1859. He was professor of history and archaeology in Franklin and Marshall College from 1873 to his death, and acted as president of the college in 1904 and 1907. He was an authority on the history of the Reformed (German) church in the United States. His principal publications include: *Historic Manual of the Reformed Church* (1885); *Home Ballads and Metrical Versions* (1888); *History of the Reformed Church* (1895); *Leaders of the Reformation* (1900); *History of Franklin and Marshall College* (1903); and contributions to the *Schaff-Herzog Encyclopædia*, *Hastings Encyclopædia of Religion and Ethics*.

DU BELLAY, JOACHIM. See BELLAY.

DUBIS. See DOUBS.

DUBLIN. A maritime county in the east of Leinster Province, Ireland, bounded on the north by Meath, on the east by the Irish Sea, on the south by Wicklow, and on the west by Kildare and Meath (Map: Ireland, E 3). Area, 342 square miles; including Dublin County borough, 354 square miles. The coast, indented by creeks and bays, is 70 miles long. Dublin

is the best-cultivated county in Ireland. The chief crops are oats and potatoes. There are important fisheries of turbot, salmon, brill, sole, plaice, cod, haddock, and oysters. The manufactures (chiefly cotton hosiery, distilled and malt liquors, and ships) are mostly confined to Dublin and the vicinity of the metropolis and are of more value than in any other Irish county. Dublin, Down, Antrim (with their county boroughs), and Kildare were the only Irish counties showing an increase of population, according to the 1911 census. Dublin County increased from 148,210 in 1891 to 157,568 in 1901 and 172,394 in 1911 (exclusive of Dublin County borough). Including the county borough, the population was 416,860 in 1891, 448,206 in 1901, and 477,196 in 1911. Roman Catholics numbered about 384,912, Protestant Episcopalians 80,466, Presbyterians 9264, Methodists 5541, and Jews 3000. The large towns of the county are the urban districts constituting the suburbs of Dublin City, viz., Rathmines and Rathgar, with 38,190 inhabitants in 1911; Pembroke, 29,260; Kingstown, an important port, 17,227; and Blackrock, 9081. Dublin County returns two members to the Parliament at London, and Dublin County borough four members.

DUBLIN (Ir. *Dubh-linn*, Black Pool). The capital of Ireland, a city and county borough, situated in the Province of Leinster and geographically in Dublin County, at the mouth of the river Liffey and on Dublin Bay, an inlet of the Irish Sea, in lat. 53° 23' N. and long. 6° 20' W. (Map: Ireland, E 3). The city is generally flat. The river, running from west to east, divides the city into two almost equal portions; in its lower course it is bordered with quays, largely of granite, and, between the quays and Phoenix Park on the west, is crossed by 12 bridges. On each side there is a spacious roadway, with tall houses and excellent shops. Near the customhouse are several large docks in communication with the Royal and Grand canals; the former connecting Dublin with the North Shannon and the west of Ireland, the latter with the southern portion of the same river and the south. The harbor and docks are protected by two large breakwaters. By improvements made at the beginning of the present century vessels drawing 23 feet can lie alongside the quays at low water. In the newer parts of Dublin the streets run at right angles and are remarkable for their breadth. The most imposing is Sackville Street, which is 120 feet broad. At its north end is the Rotunda, with Rutland Square—in its centre are the beautiful Ionic portico of the general post office and Nelson's Monument (134 feet high). A feature of Dublin are the squares, which are numerous, spacious, and sometimes well kept. The southeast and northeast quarters contain many beautiful squares, with splendid streets and terraces. The centre and the northwest quarter are the great emporiums of trade and the residence of the middle classes, many of whom have private houses in the suburbs. The southwest division part of which is called the Liberties, once the seat of the silk trade, is the slum district. The streets in this quarter are narrow, crooked, and irregular. The city is surrounded by the Circular Road, nearly 9 miles in length, forming a favorite drive and promenade.

There are numerous places of worship, Catholic and Protestant, monasteries, convents, priories, and a Jewish synagogue. The most re-

markable are the Protestant churches are St. Patrick's, founded in 1190, and restored in 1864 through the munificence of Sir Benjamin Lee Guinness, and Christ Church Cathedral, founded in 1038 and restored in 1870-77 at the charge of Henry Roe; and among the Roman Catholic, St. Mary's, St. Saviour's, St. Augustine's, St. Kilvin's. The public buildings include the Bank of Ireland, formerly the House of Parliament, Trinity College, the handsome customhouse (1781-91), and the Four Courts. Dublin Castle has no pretensions to architectural beauty; it dates from the early thirteenth century, but most of it was built after the fifteenth. There are monuments of William III in College Green, now a paved street; of Nelson, the Duke of Wellington, Goldsmith, Burke, Grattan, and many others on various public sites. The environs of Dublin are especially beautiful. Rathmines, a southern suburb, is a favorite residence of the wealthier part of the mercantile community. Glasnevin, on the north, deserves special notice as the favorite residence of the poet Tickell, of Addison, Steele, Parnell, Swift, Sheridan, and many other celebrities. In the cemetery at Glasnevin lie the remains of Curran, O'Connell, and Tom Steele. Phoenix Park, at the west of the city, is a magnificent area, of over 1750 acres, and further enlarged in 1905, in some parts level, in others with broken ground, having a large amount of timber and brushwood, which shelter herds of deer. It affords ample scope for military reviews and is extensively used by the inhabitants of Dublin for recreation. The Lord Lieutenant or Viceroy of Ireland holds his court in Dublin Castle during the winter months and in the summer season removes to the Lodge, situated in Phoenix Park.

The chief educational institution of Dublin is Trinity College. (See DUBLIN, UNIVERSITY OF.) There is also the Catholic University (1854), a Jesuit institution. The Royal University of Ireland, an examining body, was dissolved under an Act of 1908 and was superseded by the National University of Ireland; the constituent colleges are University College in Dublin, University College in Cork (formerly Queen's), and University College in Galway (formerly Queen's). There are many literary and scientific societies. There are two botanic gardens. The hospitals, asylums, orphanages, and other charitable institutions are numerous and liberally maintained. The municipal affairs are under the control of a town council, comprising the lord mayor, 20 aldermen, and 60 councilors. The city owns docks and wharves, the water supply, markets, municipal tenements, and an electric-lighting plant, and maintains parks, zoological gardens, a museum and library, an art gallery, and a model school. The city sends four members to Parliament. The chief manufactures are porter, whisky, and poplin. Dublin has a large import, but a small export trade. Imports in 1911 and 1912 were valued at £2,957,741 and £3,258,654 respectively; exports, £149,491 and £155,134; net tonnage entered, 221,793 and 258,541, and cleared, 90,258 and 64,448. Its chief imports are grain, raw cotton, metal ores, timber, petroleum, sugar, cork, and butter; exports wool, manure, iron and steel manufactures, whisky. Much of the inland traffic is carried on by the canals above mentioned and by the railways extending to all parts of Ireland. Dublin County borough has an area of 7911 acres and is

the largest city in Ireland. The population in 1891 was 268,587; in 1901, 290,638; in 1911, 304,802. With its suburbs (the urban districts of Rathmines and Rathgar, Pembroke, Blackrock, and Kingstown), the population in 1911 was 403,000, while that of the metropolitan police district was about 416,000. The great majority of the inhabitants are Roman Catholics.

History. Frequently called *Bally Achlee*—(town of the hurdle ford) from the ford of hurdles that spanned the river in this vicinity, this name was probably antedated by the perpetuated *Dubh-linn* (the black pool) and the *Eblana* of Ptolemy. Christianity was introduced by St. Patrick, who in 448 baptized the King of Baile-atha-eliath. From the ninth century until 1170, with interruptions, Dublin was held by the Danes. The Anglo-Norman Conquest by Strongbow and Henry II finally dispossessed them. During this period it became an ecclesiastical centre, being made the seat of a bishopric in 1038 and an archiepiscopal city in 1152. James II held a parliament here in 1689 and founded a mint, and in St. Patrick's Cathedral William III returned thanks for the victory of the Boyne. Lord Fitzgerald (q.v.) planned to seize the city and castle during the rebellion of 1798, but was captured before the attempt was made, and Robert Emmet (q.v.) also made an unsuccessful attempt in 1803. On May 6, 1882, Lord Cavendish, the newly appointed Secretary for Ireland, and the Undersecretary Burke were murdered in Phoenix Park. Consult: Gilbert, *History of Dublin* (3 vols., Dublin, 1854-59); "Greater Dublin," in *London Municipal Journal* (1889); Gerald, *Picturesque Dublin, Old and New* (London, 1897); Gross, "Dublin," in *Bibliography of British Municipal History* (New York, 1897).

DUBLIN. A city and the county seat of Laurens Co., Ga., 54 miles south-southeast of Macon, on the Macon, Dublin, and Savannah, the Central of Georgia, and the Wrightsville and Tennille railroads, and on the Oconee River (Map: Georgia, D 3). It has a Carnegie library. Its chief industries include cotton and oil mills, fertilizer and brickworks, and manufactories of hardwood products, cigars, wagons, and staves. First settled in 1807 and incorporated about 1850, its government, under a charter of 1905, is vested in a mayor, chosen biennially, and a unicameral council. The water works and electric-light plant are owned by the city. Pop., 1910, 5795.

DUBLIN. A city in Erath Co., Tex., 90 miles southwest of Fort Worth, on the Texas Central and the Fort Worth and Rio Grande railroads (Map: Texas, C 3). It is in an agricultural, cotton, and stock-raising country, and has oil mills, cotton compress, flouring mills, creamery, roller mills, and ice and mattress factories. The city owns its water works and sewage system. Pop., 1900, 2370; 1910, 2551.

DUBLIN, UNIVERSITY OF. The chief, and for many years the only, institution for higher education in Ireland. The first University of Dublin was established in connection with St. Patrick's Cathedral in 1320, but, lacking an endowment, was never successful and perished, probably at the dissolution of the cathedral foundation by Henry VIII. The present foundation, better known as Trinity College, is unique in having the organization and functions of both a college and a university. In 1591 Queen

Elizabeth issued a charter in 1592, giving a college, as "the mother of an . . . , with the title of "the College of the Holy and Undivided Trinity, near Dublin." It was expected that other colleges would be formed about this nucleus, and that a university after the English model would gradually rise in the Irish capital. This expectation was, however, disappointed, and though the institution has flourished, it has not been in the way expected. The new foundation received little but its charter from the Queen; the Corporation of Dublin gave to it the grounds and ruins of the suppressed monastery of All Hallows, and a building fund was raised by subscription among the Irish gentry. The first chancellor was William Cecil, Lord Burghley, Elizabeth's great minister, who was also chancellor of Cambridge. The first five provosts were Cambridge men, and by this connection the influence of the English university on the Irish foundation was very strong. The exclusive royal patronage and control by the English crown promised much, but under Elizabeth the college was but poorly supported and led a precarious existence. James I supplied an endowment of some £400 a year as a pension, together with certain estates in Ulster, which insured its future. In 1601 the English troops defeated the Spanish at Kinsale, and in commemoration of their victory subscribed £1800 from the arrears of their pay to establish a library for the college. The two trustees of this fund were Dr. Challoner and Mr., later Archbishop, Ussher. Subsequently the collection of Ussher was with some difficulty purchased by the officers and soldiers of the army of the Commonwealth of Ireland, and from these two unusual contributions the foundation of the present collection was laid. The original constitution of the university, meanwhile, having been found defective, new statutes were framed and issued under the direction of Archbishop Laud in 1637. A considerable part of these are still in force. Under the present system the administration rests in the hands of a board consisting of the provost and senior fellows, in connection with the visitors, a council (since 1874), and the senate. The provost is appointed by the crown and is the chief officer of the college. The board consists of the provost and senior fellows of the college and carries on ordinary college business. The council consists of the provost, four members of the senate chosen by the senior fellows, four by the junior fellows, four by the professors not fellows, and four by the senate at large. The council coöperates with the board in regulating the studies and the appointment of professors. The senate consists of the chancellor, vice chancellor, and all masters and doctors of the university whose names are on its books. The fellows are of two grades, senior and junior. The senior fellows comprise the chief officers of the college; the junior fellows form the bulk of the tutorial force of the college. Fellows, chosen primarily by examination, are promoted by seniority. There is a considerable body of professors, some 40 in all, besides lecturers, and some special instructors. There are 70 scholarships, besides many prizes. As at Cambridge, the old distinctions among the undergraduates still exist. There are four classes of students; noblemen, sons of noblemen, and baronets; fellow commoners; scholars, pensioners, or ordinary students in art; and sizars, or poor students, assisted by the college. Of the last there

are some 30, who obtain their positions by competitive examination. Since 1904 women have been admitted to all classes, examinations, and degrees in arts, medicine, and law.

Entrance to the college is by examination, and there is an additional examination for high places at entrance. The majority of men enter the arts course, but there are courses leading to degrees in music and in engineering, distinct from that in arts. The course of study usually extends over four years and may be an ordinary or an honor course. In the latter, higher requirements are demanded. In each year one term of the three must be "kept" by examination, the others by attendance on lectures or by examination. The required course for the ordinary degree in arts gives the best idea of the First year (junior fres . . . , Greek, Latin, Latin composition, English composition; second year (senior freshman), the same, with the addition of logic and mathematical physics in the second and third terms. The final freshman examination covers all these. In the third year (junior sophister) mathematical physics, logic, and English composition are required throughout the year, astronomy and psychology each for one term, the rest of the work being optional. In the fourth year (senior sophister) astronomy, psychology, and ethics, and English composition are compulsory throughout the year, the rest of the work being optional. The degree examinations cover these as well as the optional work. Men going into the profession of law, medicine, and divinity are allowed to anticipate their professional courses in these last two years. These courses lead to the degree of B.A. For the degree of M.A. a candidate must be a B.A. of at least three years' standing. A doctor of science must be a B.A. of three years' standing, present a thesis, and, if required, pass an examination. The same requirements, in some form or other, apply to all other advanced degrees, in literature, divinity, medicine and surgery, engineering, and music.

The university possesses a number of valuable collections. The library contains over 255 000 volumes. The astronomical observatory of Trinity College is situated at Dunsink, 5 miles from the college. There are, belonging to the college, museums of natural history, astronomy and zoölogy, geology and mineralogy, engineering, pathology, materia medica, and an herbarium, botanical laboratory, and gardens. The grounds of the college in the centre of the city are extensive, the buildings large and handsome. Among the more famous names connected with the institution may be mentioned Archbishop Ussher, Burke, Sheridan, Swift, Goldsmith, Berkeley, and Sir W. Hamilton. The university sends two members to Parliament. Consult: *The Book of Trinity College* (Dublin, 1591-1891); Mahaffy, *An Epoch in Irish History: Trinity College, Its Foundation and Early Fortunes* (London, 1903); *The Irish University Question* by "Catholicus" (ib., 1905); *Dublin University Calendar*.

DÜBNER, düb'nër, JOHANN FRIEDRICH (1802-67). A German classical scholar. He was born at Hörsehgau, near Gotha, and, after devoting six years to philological studies at the University of Göttingen, was professor at the Gymnasium at Gotha from 1826 to 1831. During that period he attracted attention by his admirable critical edition of Justin (1831) and by an edition of

Persius. In 1832 he was called to Paris to superintend Didot's new edition of Stephanus' *Thesaurus Linguae Graecae*. Afterward he was employed on Didot's *Bibliotheca Graeca*, to which he contributed the critical editions of Plutarch's *Moralia* (1841); of Maximus Tyrius (1841); of Arrian (1846); and of Himerius (1849); the scholia to Aristophanes (1843) and Theocritus (1849); and the *Anthologia Palatina* (1864). He wrote the commentaries on Horace and Vergil for Didot's *Collection Elzévirienne*; at the request of Napoleon III, prepared a critical edition of Cæsar (1867); and published a number of school editions of the classics. Consult Godefroy, *Notice sur Friedrich Dubner* (Paris, 1867).

DUBNO, дубно́. A town in the Russian Government of Volhynia, situated in a marshy region on the Ikva, a little over 30 miles from the Austrian frontier (Map: Russia, C 4). Pop., 1897 (last census), 13,800, mostly Jews.

DUBOC, dy'bók', EDUARD (1822-1910). A German author of French extraction, who wrote under the pseudonym "Robert Waldmüller." He was born in Hamburg, the son of Edouard Duboc, author of *Dignité de l'homme*, began a business career, but after spending two years in Italy and Greece turned to literature in 1857, settling in Dresden in 1859. In addition to the tragedy *Brunhild* (1873), the drama *Die Tochter des Präsidenten* (1880), and translations of the poems of François Coppée and of Alfred Tennyson's *Enoch Arden* (1867; 40th ed., 1897) and *In Memoriam* (under the title *Freundesklage*, 5th ed., 1876), he wrote a great number of poems, novels, and romances, some of the more popular of which are: *Unterm Schindeldach*, idyls (1851); *Das Vermächtnis der Millionärin*, a novel (1870); *Walpra*, an elegy (1873); *Leid und Lust*, a novel (1874); *Die Somosierra* (1881); *Darja* (1884); *Felicitas* (1893); *Liebestürme* (1897). His *Dorfdäylen* are his best poems.

DUBOC, JULIUS (1829-1903). A German author and philosopher, brother of Edouard Duboc. He was born in Hamburg and studied law and history in Giessen, Leipzig, and Bonn. His publications include: *Geschichte der englischen Presse* (after Grant, 1873); *Die Psychologie der Liebe* (1874; 2d ed., 1883); *Hundert Jahre Zeitgeist in Deutschland* (1889; part ii, 1893); *Die Frauenfrage in Deutschland* (1892). In addition to these he published a great number of essays, a collection of novelettes, *Herzensgeschichten: Ein Novellenstrauss* (1888), the one-act drama entitled *Das Herabblat* (published under the pseudonym of "Julius Lanz"), and the drama *Die Freunde* (1902).

DU BOIS, dy bois'. A borough in Clearfield Co., Pa., 128 miles northeast of Pittsburgh, on the Buffalo and Susquehanna, the Buffalo, Rochester, and Pittsburgh, the Lake Shore and Michigan Southern, and the Pennsylvania railroads (Map: Pennsylvania, D 4). The chief industry of the borough is the mining of bituminous coal, and there are glass and clay works, blast furnaces, large railroad repair shops and a roundhouse, machine shops, a foundry, a tannery, an ice-cream factory, etc. The borough contains a general hospital and owns its water works. Settled in 1873, Dubois was incorporated as a borough in 1881. Pop., 1900, 9375; 1910, 12,623; 1914 (U. S. est.), 14,007.

DU BOIS, AUGUSTUS JAY (1849 -). An

American mechanical and civil engineer, born at Newton Falls, Ohio. He graduated in 1869 at Sheffield Scientific School (Yale), studied for two years (1872-74) at the Mining School of Freiberg (Saxony), and from 1875 to 1877 was professor of civil and mechanical engineering at Lehigh University. In 1877-84 he was professor of mechanical engineering at Sheffield Scientific School and in 1884 was appointed to the chair of civil engineering in the same institution. His publications include: *A New Method of Graphical Statics* (1875-76); a translation and edition of two volumes of Weisbach's *Ingenieur und Maschinen-Mechanik* (*The Theory of the Steam Engine*, 1878); a translation of Röntgen's *Warmetheorie* (*The Principles of Thermodynamics*, 1880); *The Strains in Framed Structures* (1883; 11th ed., 1900); *The Elements of Mechanics* (3 vols., 1893-95); *Mechanics of Engineering* (2 vols., 1908-09).

DUBOIS, dy'bwä', (CLÉMENT-FRANÇOIS) THÉODORE (1837-). A French organist and composer. He was born at Rosnay, Marne, and, after instruction under local teachers, entered the Paris Conservatory in 1853. His teachers were Marmontel (pianoforte), Benoist (organ), Bazin (harmony), and Ambroise Thomas (fugue and composition). He graduated in 1861, winning the Grand Prix de Rome with his popular cantata *Atala*. His most important appointments were: choirmaster of Sainte-Clotilde; organist at the church of the Madeleine; professor of harmony at the Conservatory (1871); professor of composition at the same institution (1891); and successor of Gounod as chairman of the Academy (1894), and of A. Thomas as director of the Conservatory (1896-1905). He was also elected an officer of the Legion of Honor and made a member of many important foreign orders. He was especially successful in organ composition, possibly because of his brilliancy as an organist, although he also won wide recognition for operatic and orchestral compositions. His more important works are: *Aden Hamet*, a grand opera, produced in 1884; a three-act *Idylle dramatique* (1895); three oratorios—*Les sept paroles du Christ* (1867), *Le paradis perdu* (1878), and *Notre Dame de la Mer* (1897). Among his many other published works are cantatas; several masses; many orchestral works; arrangements for organ, harp, and other instruments; concertos for both organ and violin; and several impressive *a cappella* choruses.

DUBOIS, EDMOND PAULIN (1822-91). A French hydrographer and inventor of marine instruments born in Brest. In 1851 he was appointed professor at the Ecole Navale in Brest. His most important inventions are a gyroscope and a compass equipped with a double needle to determine the deflection caused by the iron-work of a vessel. In addition to contributions on astronomy and hydrography to scientific magazines, he published the following important works: *Cours d'astronomie* (1855; 3d ed., 1876); *Etude historique et philosophique sur le mouvement du globe* (1861); *Cours de navigation et d'hydrographie* (2d ed., 1869); *De la déviation des compas à bord des navires* (1867); *Les passages de Vénus sur le disque solaire* (1883); *Résumé analytique de la théorie des marées* (1885); *Cercle nautique* (1888). In 1865 he translated Gauss's *Theoria motus corporum* into French with notes.

DUBOIS, GUILLAUME (1656-1723). A cardinal and prime minister of France. He was

born at Brives-la-Gaillarde, the son of a country doctor, and was educated at the Collège Saint-Michel in Paris. Appointed tutor to the young Duc de Chartres (the future Duke of Orléans), he gained great influence over his pupil, whose constant companion he was in peace and in war, and whose marriage to Mademoiselle de Blois, a natural daughter of Louis XIV, Dubois brought about. His political career began in 1701, when he was made Secretary to the French Embassy at London. In 1715 he became private secretary to his pupil, now the Regent, and quickly made himself the virtual ruler of France. The key of his foreign policy was the bringing of Philip of Spain's ambition and the overthrow of Philip's Minister, Alberoni. Dubois effected this by means of the famous union of England, France, and Holland in the Triple Alliance (1717), later changed to a Quadruple Alliance by the accession of Austria. This coalition worked a revolution in French policy, since by the new arrangement friendship was made with England, an ancient enemy, and enmity declared against an old ally, Spain. The last years of Dubois were filled with great labors and high honors. In rapid succession he became Archbishop of Cambrai (1720), Cardinal (1721), and Prime Minister (1722). He died Aug. 10, 1723. Dubois has been portrayed by his enemy, Saint-Simon, as a deformed and debauched pander to the Regent. It is known now that malice has darkened the picture, though Dubois was by no means an exemplary citizen or statesman. The political genius of the man, however, can hardly be denied. Consult: *Séverin, Mémoires secrets et correspondance inédite du cardinal Dubois* (Paris, 1815); Capefigue, *Le cardinal Dubois* (ib., 1861); and for a treatment of Dubois's foreign policy, Wiesner, *Le régent, l'abbé Dubois et les Anglais* (ib., 1891).

DUBOIS, JEAN ANTOINE (1765-1848). A French missionary in the East Indies, born at Saint-Raméze, Ardèche. He wrote several books concerning India, the best known of which is the *Descriptions of the Character, Manners, and Customs of the People of India, and of their Institutions, Religious and Civil* (1816), a standard work which was brought out in a new edition in London in 1900.

DUBOIS, LOUIS (1830-80). A Belgian painter. He was born in Brussels and studied under Couture in Paris. His paintings, which strongly suggest the influence of Courbet, are full of animation and a coloring which at times strikingly reminds one of the brilliancy of Jordaens and Frans Hals. In the choice of subjects Dubois reveals versatility, while his treatment of them entitles him to be ranked among the most prominent representatives of the realistic school. His subjects are portraits, landscapes, marines, animal and genre pictures, and still life. His works are of unequal merit, the earliest being considered the best. They include: "Priest Preparing for Mass" (1857); "The Storks" (1858) and "Landscape with Dead Roe" (1863), both in the Modern Gallery, Brussels; "Rice Eater" (1872); "Billiard Player" (1878); "The Meuse near Dordrecht."

DUBOIS, PAUL (1829-1905). A French sculptor and painter. He was born at Nogent-sur-Seine (Aube), and after studying law for several years he spent two years in the atelier of the sculptor Toussaint, and from 1859 to 1862 was in Italy. In 1863 he achieved success with "St. John the Baptist" (Luxembourg). The

most popular of his earlier works, "The Florentine Minstrel" (also in the Luxembourg), won a medal of honor in 1865 and shows Dubois's study of Renaissance models. His monument to General Lamoricière, in the cathedral at Nantes, received the medal of honor at the Exposition of 1878. It is designed in Renaissance style and decorated with statue and bas-reliefs. His other works in sculpture include a "Virgin and Child" (1867, Church of the Trinité, Paris); "Birth of Eve" (1873); a figure of "Grief" for his father's tomb at Nogent-sur-Seine; "Narcissus" and "The Remembrance" (Luxembourg); an equestrian statue of the Constable de Montmorency (1886, castle of Chantilly); a statue of Jeanne d'Arc (1889) for the city of Rheims—the most popular of all his works—which had the honor of a commemorative medal; "Alsace and Lorraine" (1900), a replica of which he had finished just before his death; and portrait busts of Pasteur, Baudry, Gounod, Henner, and others. He is especially well represented in the Ny-Carlsberg Glyptotek, Copenhagen. Dubois is one of the most important figures in French sculpture of the nineteenth century. He is the foremost representative of the Renaissance influence as distinguished from the classic. His work is characterized by infallible good taste, subtle workmanship, and high perfection of detail. Among other honors he received the grand cross of the Legion of Honor (1896) and was a member of the Institute. He was conservator of the Luxembourg (1873-78) and director of the Ecole des Beaux-Arts from 1878 until his death. His work as a painter is mostly in portraiture, and a notable example of it is "My Children" (1876)—both in color and drawing an admirable work. Consult Brownell, *French Art* (New York, 1892).

DUBOIS, PAUL. See PAUL-DUBOIS, LOUIS FRANÇOIS ALPHONSE.

DU BOIS, du-bois', WILLIAM EWING (1810-81). An American numismatist, born at Doylestown, Pa. He was assistant assayer in the United States Mint in Philadelphia, Pa., from 1836, and chief assayer from 1872. In addition to accumulating the comprehensive and important coin collection at the mint he published a *Manual of Gold and Silver Coins of All Nations* (1842-51).

DU BOIS-REYMOND, du bwä'rä'môn', EMIL HEINRICH (1818-96). A German physiologist, born in Berlin. He was educated at the College of Neuchâtel and became a theological student at the University of Berlin, but, under the influence of Mitscherlich, soon abandoned theology to devote himself to chemistry, natural philosophy, mathematics, and geology. Dr. Edward Hallmann finally directed him towards medicine, and he became a pupil of Johannes Müller, the famous anatomist and physiologist. In 1841 young Du Bois-Reymond undertook to solve the problems of animal electricity proposed by Matteucci and Nobili and entered upon the experimental work which he prosecuted for 40 years. An extensive account of his first researches, with a description of the immense number of experiments made, largely by new methods and with apparatus of his own invention, appeared under the title *Untersuchungen über tierische Elektrizität* (2 vols., 1848-49). Previous attempts to observe electrical phenomena during the contraction of muscle had failed, and Du Bois-Reymond was the first to

suggest tetanizing muscles in order to obtain an increased duration of contraction for observation. He discovered how to cause deflection of the magnetic needle by the voluntary contraction of living muscle; demonstrated electric phenomena in a tetanized nerve; caused a deflection of the needle of the galvanometer by molecular change, accompanying nerve currents; and showed that "negative variation" is transmitted in a motor nerve from periphery to centre and in a sensory nerve from centre to periphery. In 1848 Du Bois-Reymond was elected a member of the Royal Academy of Sciences of Berlin. In 1858, upon the death of Johannes Müller, he succeeded to the chair of physiology in the University of Berlin and became director of the laboratory. In 1867 he became permanent secretary of the Academy of Sciences of Berlin and later was made Imperial Privy Councillor. Several of his experimental and practical researches were in the domain of electricity without reference to physiology. These include his important investigations of the aperiodic state of the magnetic needle induced by high dampening powers. He invented the method of reading messages over the Atlantic cable by watching the beam of light reflected from a mirror attached to the needle of a galvanometer. He demonstrated, controverting Berzelius and Liebig, that the reaction of muscle substance at rest is neutral or slightly alkaline, and acid after death, while in the act of contraction acid is evolved. Du Bois-Reymond was a very successful teacher, and a popular lecturer in German, French, and English. He ranks, with Helmholtz and Virchow, as one of the greatest scientists Germany ever produced, his researches having laid the foundation of all our true knowledge in connection with animal electricity, and his observations forming permanent scientific material. Prof. Burdon Sanderson remarked of him, "Du Bois-Reymond probably never made an incorrect observation or performed a faulty experiment." Besides the works mentioned, he published: *Ueber die Grenzen des Naturkennens* (6th ed., 1884); *Gesammelte Abhandlungen zur allgemeinen Muskel- und Nervenphysik* (2 vols., 1875-77); *Reden* (2 vols., 1886-87). His *Vorlesungen über die Physik des organischen Stoffwechsels* were published posthumously (1899). Consult Engelmann, *Gedächtnisrede auf Emil Du Bois-Reymond* (Berlin, 1898), and Stirling, "E. Du Bois Reymond," in the *Medical Chronicle*, January, 1897 (London, 1897).

DU BOIS-REYMOND, PAUL (1831-89). A German mathematician, brother of Emil Du Bois-Reymond. He was born in Berlin, studied medicine in Zurich, and afterward went to Königsberg, where he devoted himself to physics and mathematics. In 1865 he became lecturer in mathematics at Heidelberg and was appointed professor of mathematics at Freiburg (1870), Tübingen (1874), and in the Berlin Technological Institute (1884). His mathematical work was chiefly on differential equations, series, and the theory of functions. His *Abhandlung über die Darstellung der Funktionen durch trigonometrische Reihen* (1876) and his *Zwei Abhandlungen über unendliche und trigonometrische Reihen* (1871; 1874) have been edited by Jourdain (Leipzig, 1913).

DUBOSARY, dōō'bōs-sā'rē, or **NOVIE DUBOS-**

SARY. A town in the Russian Government of Kherson, situated on the Dniester, 85 miles northwest of Odessa (Map: Russia, C 5). It has some trade in tobacco, wine, grain, and other agricultural products of the surrounding district. The town was founded at the end of the eighteenth century. Pop., 1897 (last census), 13,200, consisting of Moldavians, Russians, and Jews.

DUBOSC, du'bōsk'. The highwayman for whose crime Lesurques is arrested, in *The Lyons Mail* (1854) by Charles Reade, adapted from the French *Courrier de Lyons* by Moreau, Siraudin, and Delacour (Paris, 1850). Sir Henry Irving assumed this double rôle with great success.

DU BOSE, WILLIAM PORCHER (1836--). An American theologian, born at Winnsboro, S. C. He studied at South Carolina Military Academy, the University of Virginia, and the Theological Seminary of South Carolina. During the Civil War he was chaplain of Kershaw's Brigade in the Confederate army. Ordained in 1865 a priest in the Protestant Episcopal church, he served as rector of St. John's Church, Winnsboro (1866-67) and of Trinity Church, Abbeville, S. C. (1868-71). From 1871 to 1894 he was chaplain and professor of ethics and New and Old Testament language and interpretation at the University of the South; from 1894 to 1908 he held the chair of New Testament language and interpretation and was dean of the divinity department. His writings include: *The Principles of the New Testament* (1892; new ed., 1906); *The Ecumenical Councils* (1896); *The Gospel in the Gospels* (1906); *The Gospel According to St. Paul* (1907); *High-Priesthood and Sacrifice* (1908); *The Reason of Life* (1911); *Turning Point in my Life* (1912).

DUBOST, ANTONIN (1844--). A French politician, born at Arbresle, Rhône. For a time he was a contributor to *La Marseillaise*. He held various offices, becoming secretary general of the prefecture of police in 1870, préfet of Orne in 1871, Councilor of State in 1879, president of the general council of Isère in 1893, and Minister of Justice in the Casimir-Perier cabinet of 1893-94. In 1897 he became a senator and in 1906 was elected President of the Senate. He pointed out to the government the bad effects of the teaching of the Catholic clergy as tending to turn their pupils against the Republic. He wrote the valuable historical works: *Les suspects en 1858* (1867); *Les conditions du gouvernement en France* (1879); *Danton et la politique contemporaine* (1880); *Danton et les massacres de septembre* (1885).

DUBOVKA, dōō-bōv'kā. A river port in the Russian Government of Saratov, situated on the right bank of the Volga, about 30 miles above Tzaritzin (Map: Russia, F 5). Formerly a place of considerable trade in agricultural products, Dubovka had lost its commercial importance since the completion of the railway line connecting Kalach on the Don and Tzaritzin on the Volga. Pop., 1897 (last census), 16,900.

DUBS, dōōps, JAKOB (1822-79). A Swiss statesman. He studied law at Heidelberg, Bern, and Zurich; held several official positions in his native canton; was elected a member and in 1857 president of the Federal Court; and in 1864 and 1868 was elected President of the Confederation. In politics he was liberal and progressive. Among his publications are *Die*

Schweizer Demokratie, in ihrer Entwicklung (1866), and the valuable *Das politische Leben der schweizerischen Eidgenossenschaft* (1877-78).

DUBUC', SIR JOSEPH (1840-1913). A Canadian jurist. He was born at St. Martine, P. Q., and was educated at Montreal College and McGill University. He studied law, and was called to the bar of Quebec in 1869, and, after removing to Winnipeg, was called to the Manitoba bar in 1871. He was elected a Conservative member of the Manitoba Legislature in 1870 and in 1875-78 was Speaker of that body. He was also appointed a member of the Executive Council of the Northwest Territories in 1872, and in 1874 he was its legal adviser. When Manitoba University was founded, in 1878, he became one of its councilors, and in 1888 he was appointed its vice chancellor, retaining both these positions until his death. He was also superintendent of the Roman Catholic section of the Manitoba Board of Education. In 1879 he was appointed a puisne judge of the Court of Queen's Bench, and in 1903 he became Chief Justice, an office from which he retired in 1910. In 1912 he was knighted.

DUBUFE, du'bu'f', EDOUARD (1820-83). A French portrait and figure painter, born in Paris. He was a pupil of his father, Claude Marie Dubufe, and of Paul Delaroche, and his earlier works were mostly religious. His chief success, however, was in portrait painting, to which he afterward confined himself. His works were well drawn, and their good finish, together with their smooth and elegant coloring, made them popular, especially among ladies of rank. Among his sitters were the Empress Eugénie (1853), Rosa Bonheur (1857), the Princess Mathilde (1861), and the Marquise de Gallifet. Among his portraits of men, which are better than those of women, were those of Gounod (1867), Dumas fils (1873), Emile Augier (1876), and Philippe Rousseau (Louvre). Besides his portrait, the best known of his paintings are "The Peace Congress of 1856 at Paris" (1857, in the Gallery of Versailles), and a theatrical representation of the "Prodigal Son" (1866), in the manner of Paul Veronese. He was made Chevalier of the Legion of Honor in 1853 and officer in 1869 and received a first-class medal in the Salon of 1844.

DUBUFE, EDOUARD MARIE GUILLAUME (1853-1909). A French decorative painter, born in Paris. He was the pupil of his father, Edouard Dubufe, and of Mazerolle. His works include figures and portraits, but he is especially known by his large allegorical paintings, which are warm in color and executed with freedom and skill in design, but without much force. Notable among these are his "Sacred and Profane Music" (Amiens Museum), and "The Trinity of Poets." He decorated with great elegance the ceiling of the foyer of the Comédie Française (the sketch of which is in the Luxembourg), portions of the Hôtel de Ville, of the Salle des Fêtes, Palais de l'Élysée, and the new Sorbonne. He received a first-class medal in 1889 and was made an officer of the Legion of Honor in 1900. He died at sea on a voyage to Buenos Aires.

DUBUQUE, du-buk'. A city, port of entry, and the county seat of Dubuque Co., Iowa, 167 miles by rail west by north of Chicago, Ill., and 205 miles northeast of Des Moines, on the west bank of the Mississippi River, and on the Chicago Great Western, the Illinois Central,

the Chicago, Burlington, and Quincy, and the Chicago, Milwaukee, and St. Paul railroads (Map: Iowa, G 2). It has communication by boat with other points on the river and is connected with the opposite shore by three bridges, one of which, 2000 feet long and 56 feet above high water, cost \$135,000. Dubuque is built on and at the foot of picturesque bluffs. The business district occupies the lower level and is regularly laid out with broad streets. The city contains the Carnegie-Stout library; a fine United States government building, including the post office, customhouse, Federal courts, etc.; seven asylums and hospitals; a sanitarium; Earl Point Park; and many educational institutions, among which are St. Joseph's College and Mount St. Joseph's Academy (Roman Catholic), Wartburg Seminary (Lutheran), the German Presbyterian Theological School of the Northwest, and the Iowa Institute of Science and Arts. Dubuque is an important market for agricultural produce and the centre of a large wholesale and jobbing trade and of the lead and zinc mining industry of the Northwest. It has railway repair shops, enamel works, flouring and lumber mills, pork-packing houses, iron and brass foundries, breweries, and manufactures of boots and shoes, carriages and wagons, agricultural implements, hardware, leather, furniture, toys, notions, bricks, oils, engines, boilers, steel ship hulls, barrels, brooms, pearl buttons, sashes, doors, blind, etc. Some war vessels for the government have been constructed at Dubuque. The annual income and expenditures of the city in 1912 were \$923,000 and \$849,000 respectively; the principal items of expense being \$44,000 for the fire and \$36,000 for the police departments and \$126,000 for schools. The oldest city in the State, Dubuque, was named in honor of Julien Dubuque, a French-Canadian who settled there in 1788 and to whom a monument has been erected. The first permanent settlement dates from 1833; four years later it was incorporated as a town, and in 1840 it was chartered as a city. Pop., 1890, 30,311; 1900, 36,297; 1910, 38,494; 1914 (U. S. est.), 39,428.

DUC, duk, JOSEPH LOUIS (1802-79). A French architect, born in Paris, and a pupil of Percier at the Ecole des Beaux-Arts. He won the Prix de Rome in 1825. With Dubau and Labrousse he helped to initiate the so-called néo-Grec movement in architecture and was early chosen with Alavoine to design the Column of July in the Place de la Bastille (1840). In 1854 he and the architect Dommey began to enlarge and rebuild the Palais de Justice, to which he devoted the remainder of his life. Upon its completion Napoleon III presented him with a prize of 100,000 francs, a portion of which the architect set aside to establish a biennial prize for high studies in architecture. He was made a member of the Institute in 1866 and inspector general of all civil buildings in 1871. His other works include the monuments to Duban and Henri Cahieux.

DU CAMP, du kân', MAXIME (1822-94). A French author, born in Paris. His more important books are *Paris: ses organes, ses fonctions, sa vie* (6 vols., 1869-75) and a history of the Commune, *Les convulsions de Paris* (4 vols., 1878-79). His poems are gathered in *Les chants modernes* (1855) and *Les convictions* (1858). His best novel is *Mémoires d'un suicide* (1853). He wrote also a life of Théophile

Gauthier (1890), which contains most valuable and information concerning the famous and their Cénacle; was one of the founders of the *Revue de Paris* (1851-58) and a frequent contributor to the *Revue des Deux Mondes*. Consult P. Bonnefon, "Maxime du Camp et les Saint Simonien," in *Revue d'Histoire Littéraire de la France* (1910).

DU CANGE, du kânzh, CHARLES DU FRESNE (1610-88). A French scholar, one of the greatest of the seventeenth century, born at Amiens. He became government treasurer in his native town, but devoted his entire life to the study of the Middle Ages. After 1668 he lived in Paris, where he devoted himself to the study of original documents of all sorts. He displayed almost incredible industry, profound linguistic attainments, accurate knowledge in many fields, and critical insight. He is best known for his great *Glossarium ad Scriptores Mediæ et Infimæ Latinitatis*, published in 3 vols. in Paris in 1678, a veritable treasure of industry and erudition. It went through many editions, always with an increase of subject matter, and was last published in 10 vols. by Favre (Niort, 1884-87). It is the standard work on mediæval Latin. Du Cange planned a similar work for mediæval Greek and published the *Glossarium Mediæ et Infimæ Græcitatatis*, on a less extensive scale, in Lyons in 1688, the year of his death. He edited several Byzantine historians, with Latin translations, as: *Paulus Silentiarius* (1670); *Zonaras* (1687); *Nicephorus Gregoras* (published posthumously in 1702); the *Chronicon Paschale sive Aleandrinum* in 1688. Nor were his studies confined to the mediæval Greek and Latin writers. Among his many other works were *Histoire de l'empire de Constantinople sous les empereurs français* (1657) and *Histoire de l'état de la ville d'Amiens, et de ses comtes*, found among his papers and published in 1841. Consult Fougère, *Essai sur la vie et les ouvrages de Du Cange* (Paris, 1852), and Sandys, *A History of Classical Scholarship*, vol. ii (Cambridge, 1908).

DUCAS. See JOHN III, VATATZES.

DUCAS, dō'kās (Lat., from Gk. Δούκας, *Doukas*), MICHAEL. A Greek historian who lived in the fifteenth century. He belonged to the Imperial family of the same name at Constantinople. He wrote a *History of the Fall of the Byzantine Empire* (ed. by Bekker for the Bonn series of Byzantine historians, 1834), which is important for the period from the death of John Palæologus I (1355) to the capture of Lesbos in 1482.

DUCASSE, du'kās', JEAN BAPTISTE (1646-1715). A French naval officer, born at Saubusse. He entered the service of the West Indies Company and later of the Senegal Company, for whom he practically created the Colony of Senegal. He afterward entered the royal navy, in which he rose to be captain. In 1691 he was appointed Governor of Santo Domingo. He administered the affairs of the colony with great skill and conducted a successful defense against an invasion by the English and Spanish during the War of the League of Augsburg. In 1697 he commanded the land forces in the capture of Cartagena and in 1702, after a four days' fight, defeated a superior English fleet under Admiral Benbow. Being deputed in 1705 to aid Philip V in the War of the Spanish Succession, he kept open

the very necessary communication with the Indies. With the rank of lieutenant general of naval forces, he directed the blockade of Barcelona in 1714.

DUCAT. A name formerly used throughout Europe for coins of different value, mostly of gold. Ducats were first struck by the Byzantine emperors in the eleventh century, or, according to some authorities, a century later, in Sicily. The name is said to have originated from the legend found on early Sicilian pieces, *Sit tibi, Christe, datus, quem tu regis, iste Ducatus* ('Be intrusted to thee, Christ, this duchy (*Ducatus*) of which Thou art ruler'). Especially famous were the golden ducats of Venice, known as *zecchini*, or sequins. Later, Holland, the German Empire, Russia, and the states of the north began the striking of ducats. At present there are practically none of these coins in existence outside of collectors' cabinets. The value of the principal ducats formerly in circulation ranged from \$1.46 for the Venetian to \$2.32 for the Spanish and Hanoverian coin; the usual value was \$2.32. Venice and the Two Sicilies struck also silver ducats of the value of \$0.83 approximately, and Spain issued silver ducats varying in value from \$0.90 to \$1.10. In Austria-Hungary gold ducats are still coined, chiefly for the purposes of foreign trade, especially in the Levant. Quadruple ducats also are struck.

DUCCIO, dō'chō, properly DUCCIO DI BUONINSEGNA (c.1255-1319). A Siennese painter, after Giotto the foremost artist of mediæval Italy. He was born at Siena, where he passed nearly all of his life. According to Weigeld, he was probably a pupil of Guido da Siena, but Berenson and others believe that he studied with some Byzantine master, perhaps at Constantinople itself. The details of our meagre knowledge of his life are due chiefly to excerpts from the public records of Siena published by Lancini in 1898. The entries concerning Duccio begin with 1278 and are mainly of two kinds: payments for paintings executed for the city, largely covers of muniment books, "cassone" fronts, and the like; and fines, chiefly for remiss payment of debts, but occasionally for neglect of military or civic duty. On one occasion (1286) he was fined 100 pounds for a serious offense, the nature of which is not known. In 1285 he contracted with the Company of St. Mary in Florence to paint a Madonna for their chapel in Santa Maria Novella. The commission was probably executed in Florence, and the painting is generally identified by recent critics with the Ruccellai Madonna, formerly attributed to Cimabue—the masterpiece of his early period. In 1298 he was a member of the official board of the great council of Siena; in 1302 he painted a "Majestas" (now lost) for the chapel of the town hall; in 1308 he received from Jacomo Mariscotti, master of the works of the cathedral, the commission for a great altarpiece of the cathedral—an incomparable masterpiece, probably the finest of its kind ever painted. The front panel, 14 feet long and 7 feet high, is a "Majestas"—a Madonna enthroned and surrounded by a host of angels, saints, and the Apostles. The Gothic suffix contains eight scenes of the life of Mary. The reverse of the large panel contains 26 scenes from the life of Christ, painted on a golden background, with eight in the suffix representing Christ after the resurrection. The predella were painted on both sides with scenes from the life

of Christ, some of which are now in the galleries of the Berlin Museum, the Benson collection, and the National Museum, London. On its completion in 1311 the altar was borne in solemn procession to its place under the cupola of the cathedral by the clergy, the officials of the city, and all the people of Siena. It remained in place until 1506, when it was removed from the cathedral, and separated; the greater part, fortunately, is still in the museum of the cathedral. Although liberally rewarded both on this and on other occasions, and recorded as the possessor of a house in Siena and a vineyard near the city, Duccio, like many artists since then, seems to have been in constant financial difficulties. On Aug. 3, 1319, his heirs, six sons and one daughter, renounced their debt-encumbered inheritance—from which it is evident that the artist died shortly before.

Duccio's art represents the culmination of Italo-Byzantine painting. Unlike his younger contemporary, Giotto (q.v.), whose art marks the beginning of a new epoch, he was a conservative, who perfected the old. Confining himself to its prescribed formulas, he nevertheless embodied in his best work sublime conceptions and great depth of feeling. An incomparable illustrator, he tells his stories with simplicity and directness. His panels have marvelous decorative qualities, and their general effect is not unlike that of mosaics which time has bronzed. Judged from the same decorative standpoint, his line is dignified, his composition always excellent. Like all Byzantine representations, his paintings are deficient in life and movement. The style which he established was determinative for the development of the Sienese school, of which he is the real founder. What, then, was the influence which enabled him thus to perfect Italo-Byzantine art? According to Wulff, it was the French Gothic, while Weigeld thinks his improvements due to the independent study of nature. But insufficient evidence supports both hypotheses, and it seems more probable that he was under the direct influence of genuine Byzantine art, which shortly before this time experienced a great revival in the mother land. He may have acquired it from the study of Byzantine miniatures, enamels, small mosaics, and ivories, in which Italy then abounded or, as Berenson thinks, from direct training under a Byzantine master.

There is great diversity of opinion concerning the authenticity of pictures, besides those mentioned above, ascribed to Duccio. Authorities are generally agreed that the "Madonna with the Three Franciscans," a "Madonna with Four Saints," and a third Madonna in the Academy of Siena are by him. Other unquestioned works are a triptych in the National Gallery, London, a "Crucifixion" in Buckingham Palace, and Madonnas in the Gallery of Perugia and the Stroganoff collection, Rome. To these Berenson adds several others at Siena, which Weigeld considers school pieces. There is also diversity of opinion concerning a fine triptych of the "Crucifixion" in the J. P. Morgan collection, New York.

Bibliography. The principal authority is Weigeld, *Duccio di Buoninsegna* (Leipzig, 1911); but his work is by no means final. For an admirable appreciation of Duccio, consult Berenson, *Central-Italian Painters of the Renaissance* (London, 1913). Consult also

Wulff, *Repertorium für Kunstgeschichte* (1907), and the notes to the new editions of Crowe and Cavalcasell, *History of Painting in Italy*, by Douglas (London, 1908), and Hutton (ib., 1909).

DU CERCEAU, du sâr'sô'. See ANDROUET DU CERCEAU.

DU CEY, THOMAS JAMES (1843-1909). An American Catholic clergyman. He was born at Lismore, Ireland, was brought to the United States in 1848, and was educated at the College of St. Francis Xavier, New York City. In 1880 he became pastor of St. Leo's Church, which was founded by him in that year. He was widely known as a promoter of civic reform. He sums of money upon his church, in with which a building called St. Leo's Repose for the Dead was established in 1899 as a temporary resting place for the bodies of lie in New York City.

DU CHAILLU, du shâ'yû', PAUL BELLONI (1835-1903). An African explorer and author. He was born in New Orleans, La., of French Huguenot parentage, and was educated in Paris. He went at an early age to Africa, where his father was established as a trader in the Gabon country. Young Du Chaillu familiarized himself with the language and customs of the neighboring coast tribes, and after three years spent in America set out, in 1855, upon an exploring expedition into the interior of equatorial Africa. He spent nearly four years in his explorations, and his discoveries added greatly to the knowledge of the flora and fauna of Africa, although, because of their rather remarkable character, the truth of his accounts was scouted by scientists at the time. Besides being the first white man to observe and obtain specimens of the gorilla, he secured 60 hitherto unknown species of birds and accumulated much valuable information as to the life and customs of the almost unknown tribes of pygmies in the interior of the continent. His published account of his explorations and discoveries, *Explorations and Adventures in Equatorial Africa* (1861), met with a storm of ridicule and refutation. In order further to substantiate his statements, he made a second journey into equatorial Africa in 1863, where he remained until 1865 and added to his previous discoveries. His experiences on his second expedition are detailed in *A Journey to Ashang Land* (1867). In 1872-73 he made explorations in Norway, Sweden, Lapland, and Finland, and in 1898-1902 traveled through Russia. His published works, besides those named above, include: *The Gorilla Country* (1868); *Wild Life under the Equator* (1869); *Lost in the Jungle* (1869); *My Apingi Kingdom* (1870); *The Country of the Dwarfs* (1870); *The Land of the Midnight Sun* (1881); *The Viking Age* (2 vols., 1889); *The Land of the Long Night* (1900); *The World of the Great Forest* (1900).

DUCHATEL, du'shâ'têl', CHARLES MARIE TANNEGUY, COUNT (1803-67). A French statesman, born in Paris. He was Minister of Agriculture and Commerce in 1834-36, Minister of Finance in 1836-37, and Minister of the Interior in 1839-48. His most important work, based upon a careful study of the theories of Malthus, is entitled *Traité de la charité dans ses rapports avec l'état moral* (1829; 2d ed., under the title *Considérations d'économie politique*). The *Documents statistiques sur la*

France (1834) are valuable. The principal achievement of Duchatel as a legislator was the complete reformation of the tariff laws.

DUCHÉ, du'shâ', JACOB (1737-98). An American clergyman and writer. He was born in Philadelphia, of Huguenot parentage; was a member of the first class which graduated (1757) at the College of Philadelphia (now the University of Pennsylvania); studied for a time at Cambridge University, England, and in 1775 became rector of the united parishes of Christ Church and St. Peter's, Philadelphia. On the approach of the Revolutionary War he joined the Whig or Patriot party, and on Sept. 7, 1774, made the opening prayer before the Continental Congress, then assembled in Carpenter's Hall, Philadelphia. For three months after the passage of the Declaration of Independence he acted as chaplain to Congress, but when the English gained possession of Philadelphia, he abandoned the Whig cause and in October, 1777, wrote his well-known letter to Washington, urging him "to represent to Congress the indispensable necessity of rescinding the hasty and ill-advised Declaration of Independency" and, that failing, to "negotiate for your country at the head of your army." The letter becoming public, and much indignation being aroused against Duché, he went to England, where he soon attracted attention by his eloquence, and acted as chaplain to the Lambeth Orphan Asylum until 1790, when he came back to Philadelphia. Besides a number of occasional sermons, he published *Observations on a Variety of Subjects, Literary, Moral, and Religious, in a Series of Letters written by a Gentleman of Foreign Extraction, who resided some Time in Philadelphia* (Philadelphia, 1774), a book of some merit which became widely popular, was frequently republished, and is best known under the title *Caspiana's Letters*. He also published *Discourses on Various Subjects* (London, 1779), which passed into several editions. Consult a brief sketch in Tyler, *Literary History of the American Revolution* (New York, 1897).

DUCHENNE, du'shên', GUILLAUME BENJAMIN AMAND (1806-75). A French physician, called "Duchenne de Boulogne," born at Boulogne-sur-Mer, and educated in Paris. Here he became established in 1842 and soon acquired fame as an investigator in electric diagnosis and electrotherapeutics, of which science he is sometimes considered the founder. He was a pioneer in the localization of the electric current and its adaptation in determining the physiology of the various muscles of the body. Scarcely less important were his researches on the pathology of the nervous system. His numerous publications include: *De l'électrisation localisée et de son application à la pathologie et à la thérapeutique* (1855; 3d ed., 1872); *Mécanisme de la physiologie humaine, ou analyse de l'expression des passions* (1862); *Physiologie des mouvements* (1867).

DUCHESNE, du'shân', ANDRÉ (in Latin, ANDREAS CHESNIUS, DUCHENIUS, or QUERCETANUS) (1584-1640). A French historian, sometimes called the "Father of French History." He was born in Touraine and studied in London and Paris. Under Richelieu's ministry he was appointed royal geographer and historiographer. Among his writings were: *Historie Normannorum Scrip-*

tores Antiqui (1619); *Histoire des rois, ducs, et comtes de Bourgogne* (2 vols., 1619-28); *Histoire généalogique de la maison de Montmorency et de Laval* (1624); *Histoire généalogique de la maison de Vergy* (1625); *Histoire généalogique de la maison de Guiches* (1631); *Historia Francorum Scriptores Coetanei ab ipsius Gentis Origine ad Philippi IV Tempora* (5 vols., 1636-49; vols. iii-v were written by his son, François Duchesne).

DUCHESNE, JACQUES CHARLES RENÉ ACHILLE (1837-). A French soldier. He was born in Sens, France. He distinguished himself in the Franco-Prussian War in 1870-71, in Tongking in 1883, became a general of brigade in 1888 and of division in 1893, and in 1895 was commandant of the expedition which conquered Madagascar. He became general of division and a member of the Superior Council of War (1900). Consult his elaborate official *Rapport* (Paris, 1897) on the Madagascar campaign.

DUCHESNE, LOUIS MARIE OLIVIER (1843-). A French Catholic scholar, born in Saint-Servan, Brittany, the son of a sea captain. He traveled in the East in 1874 and 1876, and in 1877-85, after studying with De Rossi and receiving the degree of Litt.D. for a thesis on the *Liber Pontificalis* (a remarkable piece of critical analysis), he taught Church history in the Catholic Institute, from which he went to the Ecole Pratique des Hautes Études and then to the French school at Rome as its director. In January, 1911, he was elected to the French Academy to succeed Cardinal Mathieu. He was president of a papal commission appointed in 1902 to consider the revision of the breviary. He edited the *Liber Pontificalis* (1886-92) and wrote *Origines du culte chrétien* (1889; Eng. trans. by McClure, *Christian Worship*, 1902), *Fastes épiscopaux dans l'ancienne Gaule* (1894-99), *Histoire ancienne de l'église* (1906 et seq.; Eng. trans., 1909-13, *Early History of the Christian Church*), which was put on the Index, and many articles for the *Bulletin critique*,—which he founded to popularize his critical treatment of church history.

DUCHESNE, PÈRE. See HÉBERT, JACQUES RENÉ.

DUCHESNOIS, du'shâ'nwâ', CATHERINE JOSÉPHINE (properly RAFIN) (1777-1835). A French actress, born at Saint-Saulves (Nord). She made her début at the Comédie Française in Racine's *Phèdre*. She was received with enthusiasm and for five years was the favorite of the Parisian public. Then the beautiful Mademoiselle Georges appeared, and the two actresses began an active rivalry which was taken up by the press. The wife of the First Consul, Joséphine Beauharnais, took the part of Mademoiselle Duchesnois, and she was made a *sociétaire* in 1804. In 1832 she retired from the stage. The plays in which she created rôles are *La mort de Henri IV*, by Legouvé; *Hector*, by Luce de Lancival; *Mahomet II*, by Baour-Lormian; and *Ulysse*, by Lebrun.

DUCHESSE, THE. See HUNGERFORD, MARGARET.

DUCHESSE OF MALFI, THE. A tragedy by John Webster. The chief source of the play is one of Bandello's *Novelle*. It was produced about 1612, printed in 1623, and is considered the author's finest dramatic achievement.

ZEK (1817-93). A Polish historian and ethnographer, born in the Ukraine. He studied at the lyceum of Berdichev, in 1848 assisted in founding the Società Italo-Slava, and was for a time interpreter to Achmet Pasha, Prince of Kurdistan. For his services to science he received naturalization papers from Switzerland. His works, devoted chiefly to the exposition of the thesis that Poland and Russia are fundamentally different in origin and character, include *Panslavism* (1854); *The Beginnings of the History of Poland and of Other Slavic Peoples* (1858-63); *Aryan and Turanian Peoples* (1864).

DUCIS, du'sé', JEAN FRANÇOIS (1733-1816). A French dramatic poet, chiefly noteworthy as an adapter to the French stage of Shakespeare's *Hamlet* (1767); *Romeo and Juliet* (1772); *Lear and Macbeth* (1783); and *Othello* (1792). He succeeded Voltaire in the French Academy (1779). His independent dramatic efforts were failures, but his adaptations of English models paved the way for the more daring innovations of Lemercier and the Romantic school. He was unable, however, to rise above the artificial language and conventions of the mediocre classicists of his day, which fact led him to change and weaken the strongest situations in Shakespeare's plays to suit the squeamish taste of his contemporaries. His works were collected in 6 vols. (1827). His *Hamlet*, *Macbeth*, and two other plays are in Didot's *Chefs-d'œuvres tragiques*, vol. ii. Consult Jusserand, *Shakespeare en France* (Paris, 1898), and Lacroix, *Histoire de l'influence de Shakespeare* (Brussels, 1856).

DUCK (AS. *dūce*, connected with OHG. *tūhan*, Ger. *tauchen*, to dive). The ducks are a large and well-defined group of birds of the order Anseres (q.v.) and the family Anatidæ. They are distinguished from the swans and geese by having the tarsi scutellate in front, and the sexes are unlike in color; and they are separated from the mergansers by the shape of the bill, which is broad and flattened. The term "duck" is generally restricted to designate the female, while "drake" is the term applied to the male. The ducks are largely animal feeders (insects, snails, frogs, fish, etc.), although some species are noted for their fondness for wild celery and some other vegetables. The legs are short and placed far back, so that ducks move with difficulty on land, and with the characteristic gait known as a waddle, but they are splendid swimmers, and are noted for their powers of diving and swimming under water. The neck is short as compared with geese or swans. There is a peculiar anatomical feature of the windpipe, consisting of a large dilatation of the trachea on each side at its bifurcation. The tongue is large and fleshy and very sensitive. The plumage is remarkably thick, soft, and compact. The wings are stiff, strong, and pointed, giving the power of rapid and vigorous flight, though the speed of wild ducks has probably been exaggerated. The tail is of variable shape and made up usually of 14 or 16 feathers. The oil gland is always present and well developed, with two openings, and crowned with a tuft of feathers. The ducks have been easily tamed, and many breeds are known which will be considered later by themselves.

Wild Ducks. The ducks are easily divisible into two groups, one of which is usually spoken

of as river ducks (*Anatinæ*), and the other as sea ducks (*Fuligininæ*). The latter have an evident lobe or web on the hind toe, which is wanting in the river ducks. These subfamilies are by no means confined to the bodies of water, which might be inferred by the names, for many of the sea ducks are abundant on our large inland lakes and rivers, while some of the river ducks are common "along shore." The sea ducks obtain their food principally by diving for it, sometimes descending, it is said, more than 150 feet; they feed by day and pass the night at some distance from the shore. The river ducks, on the other hand, feed more commonly at night and rarely dive for their food, but obtain it in shallow water by probing on the bottom. The river ducks are seldom seen in flocks of more than 50, while the sea ducks often gather in enormous flocks.

There are something like 65 or 70 species of river duck known, occurring pretty generally throughout the world, about a dozen being found in the United States. The best-known species is the common mallard (*Anas boschas*), which occurs in nearly all parts of the Northern Hemisphere and is the parent form of the breeds of domesticated duck which have originated in Europe, and perhaps those of Asia. In the United States it is far more common in the interior than on the coasts; and it is rare in New England, where it is replaced by the dusky or black duck (*Anas obscura*). The latter is found throughout eastern North America and is the commonest river duck of the New England States. It is about the size of the mallard, but the general color is dusky brown, and the sexes are nearly alike. The lining of the wings is white. The nest is on the ground, of weeds, grass, and feathers; the eggs are 8 to 10 in number, dirty yellowish drab. Like the other river ducks, the black duck is fine game and is highly esteemed for the table. By far the handsomest of America's river ducks is the beautiful wood or summer duck (*Aix sponsa*), described under WOOD DUCK. Another species of the same genus, the mandarin duck (*Aix galericulata*) of China, is

BILLS OF REPRESENTATIVE DUCKS.

1. Ruddy duck (*Erismatura rubida*), from the side, from above, and from below. 2. Widgeon (*Mareca americana*), from below showing double pectinations. 3. Mallard (*Anas boschas*), from the side and from above. 4. Bufflehead (*Charitonetta albeola*), from the side and from above.

still more remarkably adorned, though it is not perhaps any handsomer. Other well-known river ducks are the gadwalls, widgeons, shoy-

elers, pintails, and teals, all of which are treated of in the proper places. The species most nearly allied to the common duck is said to be the Javanese duck (*Anas javanensis*). The musk duck (*Cairina*) of South America has been domesticated and produces fertile offspring when mated with the common duck. The sheldrakes (*Tadorna*) are numerous in the Australian region and some parts of Asia.

Of the sea ducks, perhaps 50 or 60 species are known, widely distributed in all parts of the world, of which two dozen occur in North America, but comparatively few in the Southern Hemisphere. As a rule, they are not so good eating as the river ducks, as the flesh is coarser and is often rank in flavor. But there are some notable exceptions, such as the well-known canvasback (*Aythya vallisneria*) (q.v.), which is found in suitable localities and at the proper seasons throughout North America. Allied to these are the scaups (q.v.) and the ring-necked duck (*Aythya collaris*), which has a chestnut band around the black neck of the male. The "old squaw" (*Clangula hyemalis*) is a very striking species, which breeds in Arctic regions and winters in the United States as far south as Virginia and also in Europe and Asia. It is easily recognized by the greatly elongated middle pair of tail feathers. A very interesting duck, now believed to be extinct, is the Labrador duck (*Camptolemus labradorius*), which formerly occurred on the North Atlantic coast as far south as Long Island. (See EX-TINCT ANIMALS.) The ruddy duck (*Erismatura rubida*) is a small and attractive duck, about 15 inches long, with the throat and back rufous chestnut and the breast and belly white. The most striking characteristic is the peculiar tail; the coverts are very short, and the stiff and pointed tail feathers are bare to their bases. The ruddy duck is found from northern South America northward to Hudson Bay and is chiefly migratory in the United States. Closely related to it is the curious masked duck (*Nomonyx dominicus*) of tropical America, which is hardly more than a foot long. A very remarkable South American duck is the so-called steamer duck (*Micropterus cinereus*), the adult of which has lost the power of flight on account of the small size of the wings, but it is an expert swimmer. Its movements are so peculiar, however, as to suggest a side-wheel steamer, whence the name. The so-called "tree ducks" of the warmer parts of America are in reality geese, though the scientific name of the genus, *Dendrocygna*, literally means "tree swan." See also BROADBILL; GOLDEN EYE; EIDER; SCOTER; MERGANSER, ETC.; and other names of ducks. See also, for the capture of ducks, DECOY and TRAPPING; and for duck shooting as a sport, see HUNTING.

Domestic Ducks. The standard breeds of domestic ducks raised in the United States are: white Peking, white Aylesbury, colored Rouen, black Cayuga, colored Muscovy, white Muscovy, Indian runner, gray call, white call, black East Indian, and the crested white. Of these breeds the first seven are considered profitable to raise; the two breeds of calls and the black East Indian are bantams, and are bred more for the showroom; the crested white may be considered as almost purely ornamental. See Colored Plate of Ducks.

The Peking duck, which leads in popularity, was introduced from China since 1870. It is a

distinct type. Both male and female of standard-breed specimens have a pure yellow bill, white or cream-white plumage, and lead-colored eyes. The neck of a Peking should be gracefully curved; in the drake it should be large and rather long, while that of the duck is of medium length. The back is long and broad; the breast round, full, and very prominent. The body is long and deep, and the standard for adult birds is a body approaching in outline a parallelogram. The wings are short, carried closely and smoothly against the body. The tail is erect, more so than in any other breed. The curled feathers in the tail of the drakes are hard and stiff. These ducks are very large, some reaching as high as 20 pounds to the pair. Their flesh is very delicate and free from grossness, and they are considered among the best of table fowls. They are excellent egg layers, averaging from 100 to 130 eggs each in a season.

The white Aylesbury ducks are also popular for market purposes, especially in England and the continent of Europe. These ducks have white, soft plumage, a long wide bill of a pale flesh or pinkish color; the slender neck is long and gracefully curved, and the body is long and oval. The other breeds differ more or less from the two mentioned above and are characterized by their form, color, size, etc. The colored Rouens and muscovys have ornamental plumage. The muscovy drake has a crest, as have also both male and female of the crested white duck. The Indian runner breed is the most wide variation from the common type; it assumes an upright position, and the wings are very small; the Indian runner is a breed recently imported to the United States, and has become very popular because of its laying qualities.

Duck raising has been developed in the United States into a flourishing industry. Not many years ago the duck was considered an unprofitable fowl to raise; its flesh was never prized very highly by the masses. Ducks were raised without constraint in waterways, feeding mostly on fish and water insects. This food gave the flesh a strong fishy flavor; hence it was not particularly sought after. When properly fattened, the flesh has a very agreeable flavor and is much prized as food. Artificial incubation and brooding, combined with judicious feeding, have been instrumental in the development of the industry. The season for raising ducks is about six months in length, i.e., from February to July. The food of the duck is both animal and vegetable in nature. In the wild state it gathers its food, consisting of flag, grasses, small fishes, water insects, etc., from brooks and marshes. When the birds are raised in confinement, this diet must in a measure be imitated to get the most satisfactory results. Such foods as wheat bran, corn meal, and beef scrap, mixed with water to a mush, with grit and green food, constitute the most satisfactory diet. The food must be in a soft mushy state. Too much hard food, such as grain, does not agree with these birds, and they cannot thrive on it. While some raisers use a small allowance of grain, others do not, and it has not been proved to be of any advantage to feed it. It has been estimated that it costs from 6 to 12 cents a pound to raise a duck for market at 10 weeks of age. The cost of feed is from 4½ to 5 cents a pound,

NORTH AMERICAN WILD DUCKS

1. OLD-SQUAW (*Harelda hyemalis*).
2. GREEN-WINGED TEAL (*Nettion carolinense*).
3. BRANT GOOSE (*Branta bernicla*).
4. AMERICAN SHOVELLER (*Spatula clypeata*).

5. BUFFLE-HEAD (*Charltonetta albeola*).
6. HOODED MERGANSER (*Lophodytes cucullatus*).
7. CANVAS-BACK (*Marila valisneria*).
8. AMERICAN EIDER (*Somateria dresseri*).

and that of labor, etc., is from 4 to 8 cents a pound. It costs from \$1.75 to \$2.50 each to keep breeding ducks a year. When ducks are raised for breeders, they are fed differently from those intended for market. They are not forced as much as are the latter, and less fattening food is given them. To raise ducks successfully, it is not at all necessary that they should have access to water, except for drinking purposes; they grow and thrive as readily without. There are successful duck farms where thousands of ducks are raised without access to water save that which is given them as drink. It has been a matter of much dispute which is the better way. Some breeds of ducks are very good layers; one of the Buff Orpington, a new English breed, laid 79 eggs in 80 days. Ducks' eggs are larger than hens' eggs, but resemble them closely in composition. (See Colored Plate of Eggs.) They are much used as food, especially in Europe. All species of wild ducks are thought to be monogamous, but domesticated breeds are polygamous. Duck raising is a large industry in China, especially near Hankow, where factories prepare large quantities of albumen and egg yolks for export to Europe.

Bibliography. Consult: Howard, "Ducks and Geese," in *United States Department of Agriculture, Farmer's Bulletin* 64 (Washington, 1897); Yorke, *Our Ducks* (Chicago, 1900), a history of American ducks; Hehn, *Cultivated Plants and Domestic Animals* (trans. by Stallybrass, London, 1891); Nourse, *Turkeys, Ducks, and Geese* (St. Paul, 1909); Rankin, *Natural and Artificial Duck Culture* (South Easton, Mass., 1906); Rogeron, *Les canards* (Paris, 1903); Valentine, *The Indian Runner Duck Book* (Ridgwood, N. J., 1911); Millais, *British Diving Ducks* (2 vols., London, 1913). For wild ducks, consult the authorities referred to under **BIRD**, especially those books relating to northern latitudes. More special works of popular interest are: Elliot, *Wild Fowl of North America* (New York, 1898); Morris, *British Game-Birds and Wild-Fowl* (London, 1891); Lloyd, *Game-Birds and Wild-Fowl of Sweden and Norway* (ib., 1867); Job, *Among the Water-Fowl*, descriptions and photographic illustrations of breeding habits (New York, 1902); Cooke, "Distribution and Migration of North American Ducks, Geese and Swans," *United States Department of Agriculture, Biological Survey Bulletin* 26 (Washington, 1906); Shaw, *Wild Fowl* (London and New York, 1905).

DUCK (Dutch *doek*, towel; Icel. *dúlr*, Ger. *Tuch*, cloth, Goth. *gadauka*, table companion). An untwilled fabric of cotton or linen, not so heavy as canvas, but used for similar purposes. (See **CANVAS**.) The lighter and finer grades are used for women's and children's suits. Duck was woven in the United States in 1724 at New London, Conn., eight looms being in operation on this material; and previously, in 1722, in Rhode Island the General Assembly had voted a subsidy for each bolt of duck from hemp grown in the Province. By 1789 it was an important industry in New England.

DUCK ANT. The local name in Jamaica for the white ant or termite. See **TERMITE**.

DUCKBILL, or **PLATYPUS**. An aquatic, egg-laying mammal of the order *Monotremata*, of which only one species (*Ornithorhynchus anatinus*) is known. It inhabits the rivers of Aus-

tralia and Tasmania. The first descriptions of this singular quadruped were received with incredulity, and even when a stuffed specimen was brought to England, it was suspected to have been ingeniously fabricated. The whole length, including bill and tail, is usually from 18 to 20

THE DUCKBILL.

inches. The body is rather long and depressed, the skin loose and thickly covered with glossy hair, among the roots of which there is a layer of soft short waterproof fur like that of a beaver. The head is small and round, with small bright eyes and no external ears, although the internal ears are perfectly developed and the hearing acute; and instead of the muzzle, mouth, and teeth of an ordinary quadruped, the creature is furnished with a bill like that of a duck, but broader in proportion. This incloses the long upper and lower jaws within an extremely sensitive naked skin, almost black in color, possessing a flexible, liplike border all round the mouth. This skin is raised into a frill-like fold round the base of the bill, and, in burrowing and searching for food in the mud, the frill is turned back so as to protect the eyes. The nostrils are situated near the extremity of the upper mandible, so that the animal need only thrust the tip of its nose out of water in order to breathe. The lower mandible has transverse lamellæ, somewhat like the bill of a duck, and each jaw is

DENTITION OF DUCKBILL.

1. Left upper teeth, the ring of indurated epithelium still present. 2. Left lower teeth. 3. A similar fossil tooth of *Microlestes* (q.v.). 4. Diagrammatic section of a fully developed cornule.

furnished with two pairs of horny plates (cornules), the forward ones like sharp ridges, while those behind are broad and flattened. These serve the purpose of teeth for the adults; but true cheek teeth are present in young animals (see *Proceedings of the Royal Society of London*, vols. xliii, 1888; and xlv, 1889), which "are

functional for a considerable part of the life of the animal, cutting the gum in the usual manner, and, after being worn down by friction with food and sand, are shed from the mouth in the same manner as are the milk teeth of other mammals." The corneous ridges grow up around them and take their place. These facts are regarded as evidence that the duckbill descended from ancestors provided with persistent teeth of the ordinary kind. The tongue is small, nonextensible, partly covered with horny spines, and "has a projection towards its hinder part which serves to direct the food collected into two large cheek pouches," where it can be stored and conveniently carried to the burrow or some other comfortable eating place.

The duckbill is aquatic and a burrower, and its skeleton shows adaptation to these habits in the great strength of the bones of the limbs and the pectoral girdle. The legs are short, the forefeet have each five toes, with strong burrowing claws, and a connecting membrane for swimming, which extends even beyond the claws, but is capable of being folded back, so as not to impede their use in burrowing. The hind feet are smaller than the forefeet; they have each five toes armed with claws, and webbed, but the web does not extend beyond the base of the claws. The tail is strong, broad, and flattened, about half as long as the body, covered with longer and coarser hairs, and nearly naked on its under surface. An interesting feature is the strong horny spurs on the heels of the male, which are movable and traversed by a minute canal opening at the point, and connected at the base with the duct from a large gland at the back part of the thigh. The popular belief that these spurs were venomous, to which this animal gave support, has been confirmed by a case by Spicer ("On the effects of wounds on the human subject inflicted by the spurs of the platypus," in *Proceedings of the Royal Society of Tasmania*, Hobart, 1876), of a man who suffered precisely as if locally poisoned, following a wound from the spurs of a captive duckbill. However, as the male alone possesses these appendages, they are probably used mainly in the combats of the nuptial season.

Habits. The duckbill is as thoroughly aquatic as a beaver, spending its whole life in or near rivers, but not frequenting stagnant pools nor brackish estuaries. It swims chiefly by flipper-like movements of the webbed forefeet and dives with ease and grace. It is somewhat gregarious, but so shy as rarely to be seen even where numerous, unless quietly watched for at evening, when they "look like so many black bottles floating on the surface and sink down directly if alarmed." Each pair digs and occupies a burrow in the bank, having usually one opening beneath the water and another above it, which may run irregularly away and upward from the stream for 10 or 15 yards before it suits the owners to enlarge it into a chamber bedded with dry grass, where they sleep, rolled up in a ball, most of the day, and where the young are produced. The evil smell of these burrows is notorious in Australia. These animals rarely go ashore, and when they do so waddle about with a curious slipshod gait; yet those in captivity, where they exhibit docility and intelligence, climb about the furniture of a room with surprising agility. "The food consists of aquatic insects, small crustaceans and worms, which are caught under water, the sand and small stones

at the bottom being turned over with the bill. The creatures appear at first to deposit what they have thus collected in their cheek pouches, and when these are filled they rise to the surface and quietly triturate their meal with the horny plates before swallowing it." This food is discovered in the mud not only by an extreme sensitiveness to touch of the margin of the bill, but by smell, of which those studied in captivity show a remarkably high development. The eyes are small and half hidden, but perfect and useful. The duckbill's voice resembles the growl of a young puppy, but the animal's disposition is gentle.

Oviparous Reproduction. The duckbill, like other monotremes, actually lays eggs from which the young are hatched—a fact long disputed, and doubtfully believed by the aborigines, who were well acquainted with the haunts and habits of the animal, which they sought both as food and for its skin. The eggs are white, $\frac{3}{4}$ of an inch long by $\frac{1}{2}$ an inch broad, the shell is soft and flexible, and they contain a large amount of food yolk, as in birds' eggs. Only a few eggs are laid at a time, often only one, and it is hatched very soon after it is laid. The mother has no nipples, but has milk glands opening into little pits so that the young seem to be suckled by the ejection of the milk into their mouths, which in this early stage are smooth and fleshy. The young are blind and naked at birth.

Bibliography. Besides the treatises mentioned above, consult various articles by Owen in the *Transactions of the Philosophical and Zoological Societies of London* (London, 1832-34); Flower and Lydekker, *Mammals, Living and Extinct* (ib., 1891); Beddard, *Mammalia* (ib., 1902); "Catalogue of Papers Relating to the Mammalian Orders, Marsupialia and Monotremata," *Proceedings Linnæan Society, New South Wales*, vol. ix (Sydney, 1894); Bennett, *Transactions of the Zoological Society of London* (London, 1835); Bennett, *Gatherings of a Naturalist in Australia* (ib., 1866). DUCK HAWK. The peregrine. See FALCON.

DUCKING STOOL. A rude device, formerly in use in Great Britain and in parts of the United States, for the punishment of women convicted as common scolds (q.v.). It consisted of a rough, strong chair attached to one end of a beam, which worked on a pivot on a post at the edge of a pond or stream of water. The woman was placed in the chair with her arms drawn backward; a bar was placed across her back and in front of her elbows, another bar held her upright, and there were cords to tie her securely in. The officers charged with the execution of the sentence then took hold of a chain at the opposite end and gave her a ducking on the seesaw principle. A ducking stool was in use for the infliction of this punishment at Leominster, England, as late as 1809.

DUCKWITZ, duk'vits, ARNOLD (1802-81). A German politician. He was born in Bremen, where, after travels through England and the Netherlands, he became the foremost promoter of shipbuilding and navigation in Germany. He advised the creation of a German customs union, and the harbor improvements of Bremen were also due largely to his initiative. These innovations were followed by the establishment of a steamship line between Bremen and New York and the conclusion of a favorable postal treaty

with the United States. As Imperial Minister of Commerce and Naval Affairs (1848), he promoted the construction of the German navy of the time. In May, 1849, he returned to his native city; in 1857 he was elected burgomaster and served for six years, and was reelected in 1866. In 1873 he retired from public life. He published memoirs entitled *Denkwürdigkeiten aus meinem öffentlichen Leben 1841-66* (Bremen, 1877).

DUCKWORTH, SIR JOHN THOMAS (1748-1817). An English naval officer, born at Leatherhead (Surrey). He entered the British navy in 1759, in 1777 accompanied the frigate *Diamond* to North America as a first lieutenant, and later served under Admiral Byron in the West Indies. During the war with France he commanded the *Orion* and the *Queen* of the Channel Fleet, and in 1798 he directed the naval operations attending the capture of Minorca. In 1800 he captured a Spanish convoy from which his share of prize money was nearly £75,000. He was promoted to be rear admiral of the white in 1799 and vice admiral of the blue in 1804, and served in various capacities in the Mediterranean and the West Indies. In 1805 he directed the blockade of Cadiz, and on Feb. 6, 1806, with seven battleships of the line, two frigates, and two sloops, defeated a French squadron of five battleships and three frigates off San was sent in 1807 to dictate terms His orders proved impossible of execution; his negotiations resulted in nothing, and the Turks, advised by the French, having the shore batteries of the Dardanelles, he retreated. From 1810, in which year he became admiral, until 1813, when he was made Baronet, he was Governor and commander in chief of Newfoundland, and he was made Governor of Plymouth a few months before his death.

DUCLERC, du'klark', CHARLES THÉODORE EUGÈNE (1812-88). A French statesman, born at Bagnères-de-Bigorre. He was for some time a proof reader for *Le Bon Sens* (Paris), of which he became the editor in 1836. From 1840 to 1846 he was on the staff of the *National*, to which he contributed financial articles. The events of 1848 brought him into political life, and he served as Minister of Finance for a short time. From 1871 to 1875 he was a member of the National Assembly and in 1875 was elected its vice president. In the same year he was chosen senator for life, and was elected Vice President of the Senate in 1876. In 1882 he became Minister of Foreign Affairs and President of the Council. Soon afterward he succeeded Fréycinet as Premier, but resigned in 1883, owing to his disapproval of the policy of expelling the princes from the Republic.

DUCLÓS, du'kló', CHARLES PINOT (1704-72). A French historian, philologist, novelist, and wit. He wrote a *Histoire de Louis XI* (1745), the sound and ingenious *Considérations sur les mœurs de ce siècle* (1751), and the celebrated *Mémoires secrets sur le règne de Louis XIV, la Régence et le règne de Louis XV* (1791), among the best and most curious of the time. He also published very interesting and useful studies in the Celtic and French languages. Duclós aided in revising the *Dictionnaire* of the Academy, of which body he was made perpetual secretary in 1747. His *Œuvres complètes* (10 vols., Paris, 1806) include an incomplete autobiography. Consult Leboucq, *Un homme de lettres au XVIIIe siècle* (Paris, 1902).

VOL. VII.—20

DUCOMMUN, du'kómün', ELIE (1833-1906). A Swiss journalist and peace advocate, born at Geneva, Switzerland. Early becoming known for the boldness and liberality of his ideas, he took charge, when but 22 years old, of the *Revue de Genève*. He was also a contributor to *Progrès, Helvétie*, and the *Etats-Unis d'Europe*. For a time he served as chancellor of the Canton of Geneva, and afterward he was general secretary of the Jura-Simplon Railroad Company until it was taken over by the state. Turning his attention to the peace movement, he received from the Congress of Rome (1891) a commission to organize the International Bureau of Peace at Bern. His accomplishment of this task and other activity on behalf of world peace brought him one half of the Nobel peace prize in 1902.

DUCORNET, du'kór'ná', LOUIS CÉSAR JOSEPH (1806-56). A French historical and portrait painter, chiefly celebrated for the natural deformities which he overcame in order to paint. Having no arms, he used the brush with his feet. He studied at Lille, his native town, which furnished him with a pension to enable him to continue his studies in Paris under Lethère. His pictures are rich in color and dramatic in composition, but, as may be easily comprehended, deficient in draftsmanship. Among his chief works are the "Slave Merchant," in the Museum of Arras; portraits of the father and mother of the artist; the "Parting of Hector from Andromache," in the Museum of Lille; "Edith Finding the Body of Harold" (1855), in the Museum of Amiens; "The Repose in Egypt" and "St. Denis Preaching to the Gauls" in the church of St. Louis-en-l'Île, Paris.

DUCOS, du'kó', PIERRE ROGER, COUNT (1754-1816). A French statesman, born at Dax (Landes). In 1792 he was elected deputy from Landes to the National Convention, where he voted for the execution of Louis XVI. After acting as president of the Jacobin Club (1794), he became a member of the Council of Five Hundred, and was chairman of that body, Sept. 4, 1797, when the decree of deportation was issued against the Royalists. He was an ardent follower of Sieyès, through whose influence he became a member of the Directory. After the coup d'état of the Eighteenth Brumaire he became a member of the Consulate with Bonaparte and Sieyès and subsequently was Vice President of the Senate. After the proscription of the regicides under the Second Restoration he fled to Germany. He was killed near Ulm through the upsetting of his carriage.

DUCOUDRAY, du'koo'drá', GUSTAVE (1832-1906). A French scholar and historian. He was born at Sens (Yonne), studied at the Lycée Henri IV and the Ecole Normale Supérieure, and was connected with the cabinet of M. Duruy when the latter became Minister of Public Instruction. Subsequently he became professor of history and geography at the Ecole Normale de Saint-Cloud. His publications include, besides a series of textbooks for school use: *Cent récits d'histoire de France* (1878); *Cent récits d'histoire de France contemporaine* (1881); *Histoire sommaire de la civilisation depuis l'origine jusqu'à nos jours* (1886), translated into English and revised by J. Verschoyle as *The History of Modern Civilization* (1891); *Récits et biographies d'histoire de France* (1905).

DUCPÉTIAUX, duk'pá'té'ó', EDOUARD (1804-

68). A Belgian publicist, born in Brussels, where he devoted himself to the practice of law. He participated in the revolution of 1830 and was subsequently appointed chief inspector of the prisons and benevolent institutions of the country, an office which he held until 1861. He was long a collaborator on the *Courier des Pays-Bas* and was one of the foremost promoters of prison reform in Belgium. Among his writings are the *Mémoire sur le paupérisme des Flancs* (1844); *La question de la charité et des associations religieuses en Belgique* (1850); *De l'association dans ses rapports avec l'amélioration du sort de la classe ouvrière* (1860).

DUCROCQ, dū'krōk', THÉOPHILE GABRIEL AUGUSTE (1829-). A French jurist, born at Lille. He studied at the Lycée Louis-le-Grand and the University of Paris, and was admitted to the bar of Poitiers in 1855. In 1863 he became titular professor of administrative law in the University of Poitiers and in 1884 was called to a similar chair in the University of Paris. His *Cours de droit administratif* (1862), admired for its lucid and lucid in style, is an important work. He also published: *Le conseil d'état et son histoire* (1867); *Etudes de droit public* (1887); *Etudes d'histoire financière et monétaire* (1887).

DUCROT, dū'krōt', AUGUSTE ALEXANDRE (1817-82). A French soldier. He was educated at Saint-Cyr and served in Algeria, in Italy, and in the Franco-German War. At Sedan, when MacMahon was wounded, he took the chief command, surrendering it immediately, however, to General Wimpffen. After the capitulation he was a prisoner of war, but escaped to Paris, where he took command of the Thirteenth and Fourteenth Army Corps and participated in several sorties, among them the last disastrous one of Jan. 19, 1871. After the conclusion of peace he was a member of the National Assembly and in 1872 was appointed by Thiers commander in chief of the Eighth Army Corps, stationed at Bourges. His bitter attitude towards the Republic resulted in his being relieved of his command in 1878. He wrote: *La journée de Sedan* (1871); *La vérité sur l'Algérie* (1871); *Guerre des frontières, Wissembourg* (1873); *Défense de Paris* (1875-78).

DUCROTAY DE BLAINVILLE, dū'krōt'ā' de blān'vel', HENRI MARIE (1777-1850). A French anatomist and zoölogist. He was born at Arques, near Dieppe, and studied at the University of Paris under Cuvier, whom he succeeded as professor of comparative anatomy in 1832. He was editor of the *Journal de Physique* from 1817 to 1825. He exerted an extraordinary influence over his pupils as a lecturer. In addition to the essays published in the *Annales françaises et étrangères d'anatomie et de physiologie*, in the *Journal of the French Institute*, and in similar scientific publications, he wrote the following works: *Cours de physiologie générale et comparée* (3 vols., 1833); *Ostéographie* (26 serial numbers, with illustrations, 1839-54); *Manuel de malacologie et de conchyliologie* (1825-27); *Histoire des sciences de l'organisme et de leurs progrès comme base de la philosophie* (3 vols., 1845).

DUCTILITY .. (from Lat. *ductilis*, ductile, from *ducere*, to lead). . . . That property of some material bodies by which they are capable of being drawn out in length, while diminishing in breadth, without fracture or separation of their parts. Glass, gums, glues, resins, and some

other bodies, when softened by heat or water, may be drawn into threads. The ductility of glass seems to have no limit; at high temperature this brittle substance may be drawn into threads finer than any hair and of the highest flexibility. Metals are ductile, generally speaking, at any temperature, but their ductility varies greatly with the temperature; some—brass, e.g.—are more ductile at ordinary temperatures than when hot. The ductility of gold is very great: 500 feet of wire may be obtained from one single grain of gold. Next to gold follow, in the order of their ductility, silver, platinum, iron, copper, palladium, aluminum, zinc, tin, and lead. Platinum may be drawn out by making a bar of silver with a platinum core, drawing out the bar to extreme fineness, and dissolving off the silver with nitric acid. In this manner the wires adapted to microscopes for micrometric work are made. Such platinum wire is less than 1/1000 of an inch in diameter. See MATTER, Properties of.

DUCTLESS GLANDS. See GLANDS.

DUDAIM. See CUCUMBER.

DUDELL, düd'del, WILLIAM DU BOIS (1872-). An English electrical engineer, born in London and educated at the Collège Stanislas of Cannes and at the London Central Technical College. His most important work was in connection with the St. Louis Exposition of 1904, which he received gold medals at St. Louis (1904). He was secretary of the St. Louis International Electrical Congress in 1904 and of the International Conference on Electrical Units and Standards of 1908. In 1912 he was chosen president of the Institution of Electrical Engineers.

DUDEN, dö'den, KONRAD ALEXANDER FRIEDRICH (1829-1911). A German philologist. He was born near Wesel and studied philology at Bonn. After organizing the gymnasium at Schleiz in 1869 and continuing that institution, he was appointed in 1876 director of the gymnasium at Hersfeld, an institution which was greatly improved under his management. In 1905 he retired from active life and settled at his country home in Sonnenberg, near Wiesbaden. His important writings on modern German orthography and philology include: *Vollständiges orthographisches Wörterbuch der deutschen Sprache* (1880; 8th ed., 1907); a revision of Friedrich Bauer's *Grundzüge der neuhochdeutschen Grammatik* (5th ed., 1896; 21st ed. of original work; 23 ed., 1901); *Etymologie der neuhochdeutschen Sprache* (Munich, 1893; 3d ed. of the original work by Bauer-Frommann).

"DUDES AND PHARISEES." See MUGWUMPS.

DUDEVANT, dü'd'-vān', MADAME. See SAND, GEORGE.

DUDLAY, MLL., stage name of ADELINE ELIE FRANÇOISE DULAIT (1859-). An actress of the Comédie Française, well known in tragic rôles. She was born in Brussels and studied at the Conservatoire there. In 1876 she was engaged at the Théâtre Français and made her début in Parodi's *Rome Vaincue*. She made her reputation chiefly in the classic repertoire, notably as Camille, in *Horace*, in *Phèdre*, in *Athalie*, as Monime, in *Mithridate*, and Berthe in *La fille de Roland*. She became a member of the company in 1883.

DUDLEY. A town and parliamentary borough in Worcestershire, England, 26 miles north-northeast of Worcester and 8 miles west-north-

west of Dudley (Map: England, D 4). It is a well-built town and a chief seat of the iron trade, being in the heart of the so-called Black Country. Its noteworthy public buildings include the parish church, restored in 1862, the town hall, and the general hospital. Dudley sends one member to Parliament. The town's affairs are administered by a mayor, a municipal council of 30, and a board of aldermen of 10 members (see paragraph on *Local Government* under GREAT BRITAIN). It owns and leases its light and power plant, and it maintains public baths, four recreation grounds, two public halls, three libraries, an art school, and a fine cemetery. Dudley is well supplied with educational institutions, which comprise a free grammar school, a technical school, an art school, and art gallery, and a public library, the last four being maintained by the municipality. Its chief industries are iron and brass founding and the manufacture of bricks and glass. To the north-east of the town are the ruins of an old castle, now the property of the Earl of Dudley. It was demolished during the civil wars of the seventeenth century, was rebuilt, but was burned in 1750. Dudley was incorporated in 1865. In the vicinity are iron and coal mines and limestone quarries. The thickest coal seam worked in England, known as the "ten-yard" coal, is in this neighborhood. Pop., 1901, 48,733; 1911, 51,092.

DUDLEY. A town in Worcester Co., Mass., 16 miles (direct) south by west of Worcester, on the French River, and on the New York, New Haven, and Hartford Railroad (Map: Massachusetts, D 3). It is in an agricultural district and has a large linen mill. Pop., 1900, 3553; 1910, 4267.

DUDLEY, BENJAMIN WINSLOW (1785-1870). An American surgeon, born in Spottsylvania Co., Va. After a prolonged course of professional studies, both in this country and abroad, he settled at Lexington, Ky., in 1814. His specialty was lithotomy, or removing stone from the bladder, and he was known in England as "the lithotomist of the nineteenth century." He was professor of surgery in Transylvania University at Lexington and was the author of many papers on medical subjects.

DUDLEY, CHARLES BENJAMIN (1842-1909). An American chemist, born at Oxford, N. Y. He graduated from Yale in 1871 and received the degree of Ph.D. from Sheffield Scientific School (Yale) in 1874. He served as an assistant in physics at the University of Pennsylvania in 1875 and in the same year became chemist to the Pennsylvania Railroad Company, a connection in which he made an important investigation of metals for railroad use. He was a member of various scientific societies at home and abroad and was president of the American Chemical Society (1896-97) and of the American Society for Testing Materials (1902-08).

DUDLEY, CHARLES EDWARD (1780-1841). An American politician. He was born in Staffordshire, England, removed to Albany, N. Y., became a prosperous merchant there, and was successively State Senator (1820-25), mayor of Albany (1821-28), and United States Senator (1829-33). His devotion to astronomical science led his widow to give more than \$175,000 for the erection and endowment of the Dudley Observatory at Albany.

DUDLEY, EDMUND (c.1462-1510). An English lawyer and statesman. He studied at Ox-

ford, read law at Gray's Inn, and early became a privy councillor to Henry VII. In 1492 he helped to negotiate the Treaty of Etaples with France and in 1497 he became Undersheriff of London, a post then of considerable importance to the crown, as being useful in the collection of revenues from the great feudal chiefs. In this post he amazingly increased the King's wealth and his own. He became Speaker of the House of Commons in 1504. Upon the accession of Henry VIII he was haled before a special commission, by which an indictment was found against him on the ground of an alleged treasonable attempt to depose the throne. After a failure to escape from the Tower he was beheaded on Tower Hill. During his imprisonment he wrote a treatise in defense of absolute monarchy, entitled *The Tree of Commonwealth*, first published in 1859.

DUDLEY, EMELIUS CLARK (1850-). An American gynecologist, born at Westfield, Mass. He graduated from Dartmouth College in 1873 and from Long Island College Hospital in 1875, then entering on the practice of medicine in Chicago. In 1882 he became professor of gynecology at the Chicago Medical College. He was president of the American Gynecological Association in 1904. He published *Diseases of Women* (1898; 1899) and *Principles and Practice of Gynecology* (6th ed., 1913), and from 1902 to 1911 edited the *Gynecological Yearbook*.

DUDLEY, LADY JANE (?-1554). See GREY, LADY JANE.

DUDLEY, SIR HENRY BATE (1745-1824). An English clergyman and journalist. He was educated, probably, at Queen's College, Oxford, and took orders in the Anglican church. In 1775 he was appointed editor of the *Morning Post* and "contrived, before six weeks were over his head, to be called out for a criticism" (Peabody, *English Journalism*, 1882). He accepted so many challenges for duels that he became known as "the fighting parson." He made the *Post* the most readable and widely circulated newspaper of the time, but he also embarrassed it with expensive actions for libel. Having been at last reluctantly dismissed, he established in 1780 the *Morning Herald*, a Liberal sheet, and at about the same time the *Courrier de l'Europe* (printed in French) and the *English Chronicle*. Through the *Herald* he defended the Prince of Wales—so adequately, in fact, that by 1813 he had been presented to several Irish benefices and the rectory of Willingham (Cambridgeshire) and had been made Baronet. He was a minor contributor to the satirical *Rolliad*, which first appeared in the *Herald*, wrote for the stage, and published *A Few Observations Respecting the Present State of the Poor* (3d ed., 1802), *A Short Address to the Lord Primate of all Ireland* (3d ed., 1808), and other works.

DUDLEY, JOHN, DUKE OF NORTHUMBERLAND (c.1502-53). An English statesman. In 1542 he was made an admiral and a peer with the title Viscount Lisle. From that time he displayed notable ability in naval, military, and civil offices. Created Earl of Warwick in 1546 and five years later Duke of Northumberland, he became after the execution of Somerset (1549) second to the King in influence. He schemed to have the succession brought within his own family; and when Edward VI died, Northumberland proclaimed his own daughter-in-law, Lady Jane Grey, Queen. But, finding himself alone, he gave his support to Mary.

Nevertheless he was put to death for treason—at the last moment a penitent Roman Catholic. "Dudley was the ablest man of the time after the death of Henry VIII. He was a consummate soldier, a keen politician, and a skillful administrator. His nature was bold, sensitive, and magnanimous. . . . He was a great man, but his character was spoiled by avarice, dissimulation, and personal ambition." Consult: Tytler, *England under the Reigns of Edward VI and Mary* (London, 1839); Dixon, *History of the Church of England* (ib., 1871-91); Pollard, *England under the Protector Somerset* (ib., 1900); id., *England, 1547-1603* (ib., 1910).

DUDLEY, JOSEPH (1647-1720). A Colonial Governor of Massachusetts, the son of Gov. Thomas Dudley. He was born in Roxbury, Mass., and graduated at Harvard in 1665. He early became a member of the Massachusetts General Court and was a magistrate of Roxbury in 1673. In 1682 he was sent to England with John Richards to endeavor to prevent the threatened repeal of the Massachusetts Charter, but, virtually taking the opposite side, he dealt himself with the government, and in May, 1683, three years after his return, was appointed President of "Massachusetts, Maine, New Hampshire, and the mainland of Rhode Island west of Narraganset Bay," having previously acted for several months as censor of the press. On the coming of Governor Andros (q.v.), early in 1687, Dudley became judge of the Superior Court, but, when Andros was overthrown by the popular party, in 1689, he was arrested on a charge of tyranny and usurpation, and was imprisoned for five months, at the end of which time he was sent to England, where, however, he was almost immediately released, the English Privy Council dismissing all charges against him. He then served as Chief Justice of New York from May, 1691, to September, 1692, presiding as such over the court which sentenced Leisler and Milbourne to death; returned to England shortly afterward and served for eight years as Lieutenant Governor of the Isle of Wight. He was made colonel of an English regiment and returned to the House of Commons. In 1702, after much intriguing on his part, he was appointed by Queen Anne Governor of Massachusetts, which position he held in spite of frequent protests on the part of the people, until 1715. As Governor he stood for progressive, and, though an able administrator, frequently antagonized the colonists by his arbitrary conduct, coming into almost annual conflict, in particular, with the Massachusetts General Court over the question of a stated salary for the Governor instead of an annual grant. In the latter part of his administration—during Queen Anne's War—he was active in organizing and fitting out expeditions against the French and Indians. The historian Palfrey gives the following unfavorable estimate of Dudley's character: "Dudley united rich intellectual attributes with a grovelling soul. To his mean nature personal aggrandizement was the prime necessity. He had paid one price for it by dutiful behavior in his early years, and another by useful conduct in middle life, as often as such conduct would not thwart, and especially as often as it would further, the aims of his cupidity." For a somewhat detailed account of his administration as Governor of Massachusetts and New Hampshire, consult Palfrey, *History of New England*, vol. iv (Boston, 1859-75).

DUDLEY, PAUL (1675-1751). An American jurist, the son of Gov. Joseph Dudley. He was born at Roxbury, Mass., graduated at Harvard, and studied law in London. He was commissioned Attorney-General of Massachusetts in 1702, was promoted to the bench in 1718, was made Chief Justice in 1745, and for several years was a member of the Legislature. A learned naturalist, he was a fellow of the Royal Society of London and contributed papers on the natural history of New England to its *Transactions*.

DUDLEY, ROBERT. See LEICESTER, EARL OF.

DUDLEY, THOMAS (1576-1653). The second Colonial Governor of Massachusetts, born in Northampton, Mass. He acted for a time as a page to Lord John Compton, later Earl of Northampton, served as captain in the English army during the French expedition of 1597, became a clerk to Judge Nicolls about 1598, and from 1616 to 1628 was steward of Theophilus Clinton, Earl of Lincoln. In 1630 he emigrated to the Massachusetts Bay Colony, as Deputy Governor under Winthrop, and was, next to Winthrop, probably the most influential man in the Colony. He served 13 years as Deputy Governor, was four times Governor of the Colony—in the years 1634, 1640, 1645, and 1650—was the chief founder of Newtown (now Cambridge), Mass., took an active part in the founding of Harvard College, in 1636, and was twice elected President of the United Colonies of New England. He lived successively at Cambridge, Ipswich, and Roxbury, where he died. He was in many respects a typical Puritan, stern, unyielding, and intensely pious, and has been charged with being particularly narrow, bigoted, and intolerant—traits which many find in his dealings with Anne Hutchinson, Roger Williams, and Samuel Gorton. His latest biographer, however, strongly defends him on all these points. Dudley's daughter Anne, the poet, married Gov. Simon Bradstreet (q.v.). (See BRADSTREET, ANNE.) Consult the painstaking but somewhat partisan biography by Jones, *The Life and Work of Thomas Dudley, the Second Governor of Massachusetts* (Boston, 1899), and Deane (ed.), *The Life of Mr. Thomas Dudley . . . written, as is supposed, by Cotton Mather* (Cambridge, 1870).

DUDLEY, THOMAS UNDERWOOD (1837-1904). An American bishop of the Protestant Episcopal church. He was born in Richmond, Va., and in 1858 graduated at the University of Virginia, where for many years he was professor of Latin and Greek. During the Civil War he served in the Confederate army and rose to the rank of major in the commissary department. He studied theology in the Virginia Theological Seminary, was ordained priest in 1868, and in 1870 became rector of Christ's Church, Baltimore, of which he had been assistant rector for a year. He was Assistant Bishop of Kentucky from 1875 to 1884, when he became Bishop. He delivered the Bohnen Lectures (church of Holy Trinity, Philadelphia) in 1881, on *A Nice Discrimination the Church's Need*.

DUDLEY, WILLIAM LOFLAND (1859-). An American chemist, born at Covington, Ky. In 1880 he graduated from the University of Cincinnati. Between 1879 and 1886 he was demonstrator of chemistry and professor of chemistry and toxicology at the Miami Medical College; he then became professor of chemistry, and in 1895 also dean of the medical department, of Vanderbilt University. The first to discover

any physiologic effect from the use of the X-ray, he also demonstrated the most poisonous principle in tobacco smoke to be carbon monoxide, which deoxidizes the blood when inhaled; and he invented a process for working and electroplating with iridium. In 1909 he was United States commissioner to the Seventh Congress of Applied Chemistry at London, and in 1912 he was vice president of the section on law and legislation of the Eighth Congress of Applied Chemistry. He is author of many chemical researches.

DUDLEY, WILLIAM RUSSEL (1849-1911). An American botanist, born at Guilford, Conn. He graduated in 1874 at Cornell and studied natural history at the school established by Louis Agassiz at Penikese Island, Mass., in 1874, and at the Harvard Summer School in 1876. From 1876 to 1883 he was assistant professor of botany at Cornell and from 1883 to 1892 an assistant professor directing the study of cryptogamic botany. In 1892 he was appointed professor of botany in the Leland Stanford Junior University. His publications include contributions to scientific journals: *The Cayuga Flora* (1886); *Lackawanna and Wyoming Flora* (1887); *Manual of Histology*, with Prof. M. B. Thomas (1894).

DUDLEY DIAMOND, or **STAR OF SOUTH AFRICA**, THE. A heart-shaped jewel weighing 44½ carats, but originally twice that size, purchased by the Earl of Dudley from Hunt and Roskell for £30,000. The latter paid only £12,000 for it. It was found in 1868 by the slave of Nie Kirk, a mine owner in Africa.

DUDWEILER, dōd'vī-lēr. A town in Rhenish Prussia, on the Sulzbach, 40 miles east by north of Metz. It has extensive coal mines and manufactures iron machinery, fireproof bricks, and pottery. In the neighborhood is the celebrated Burning Mountain (Brennender Berg), a seam of coal deposits which has been burning for nearly two centuries. Pop., 1900, 16,323; 1910, 21,932.

DUE BILL. A written acknowledgment of indebtedness by the signer to the one to whom it is given. An example of its shortest form is this: "I. O. U. eight guineas. John Leslie." Another and more extended form is the following: "Due Currier and Barker seventeen dollars; value received. Frederick Lockwood." While from such an acknowledgment the common law infers an obligation by the signer to pay the specified indebtedness, the paper itself contains no actual or express promise to pay. It is the absence of such a promise that distinguishes it from a promissory note. Unlike a promissory note, also, it is not a negotiable instrument, though, as a claim or demand against the debtor, it is assignable by the payee. See **CHOSE IN ACTION**; **NEGOTIABLE INSTRUMENT**.

DUELING (Fr. *duel*, from Lat., *duellum*, a contest between two, *duo*). A duel is a prearranged combat between two persons in which deadly weapons are used. It generally takes place in the presence of witnesses (called seconds), who regulate the mode of fighting, place the weapons in the hands of the combatants, and enforce rules agreed upon. While dueling prevailed in antiquity, there is no doubt that the modern private duel grew out of the judicial duel. (See **BATTLE**, **TRIAL BY**, or **WAGER OF**.) In France it became very common after the famous challenge of Francis I to his rival Charles V in 1528. After this every man of France seemed to think that he was called upon to use

his sword in defending his honor against the slightest imputation. Some kings endeavored to suppress, while others promoted, dueling. Within 18 years, in the reign of Henry IV, it is said, no less than 4000 persons fell in duels. Rigid measures for their suppression were passed, but were rarely enforced. Up to the present time duels are much more common in France than elsewhere, but fatal results are infrequent.

In Germany dueling prevails but little outside the army, navy, and the universities. In the students' contests the vital parts of the contestants are so protected that serious injury seldom occurs. In but few places do the laws permit duels, but in a number of university cities there is no pretense of enforcing the laws. In every German regiment there is a court of honor, to determine all involved points of personal or regimental honor and to decide upon the procedure demanded by the circumstances. Where the result is a duel, and the civil authorities do not take any cognizance of the affair, the military authorities themselves rarely act. It is a point of honor, however, with the individual officer to satisfy the honor of his regiment, regardless of any punishment, that may afterward be meted out to him. The practice of dueling is common throughout all the armies of continental Europe, although in most countries it is prohibited by law.

In Great Britain, under the common law, the act of killing in a duel is held to be murder, however fair the duel may have been; but so long as public opinion approved the duel it was generally found impossible to induce a jury to convict. Legislative enactments against dueling were numerous, during the seventeenth and eighteenth centuries, but had little effect in curbing the evil. In 1844 rigid army rules were established to prevent dueling, and within the last half century but few duels have occurred in England.

How common dueling formerly was, both in Great Britain and America, may be inferred from the number of prominent political leaders who participated in duels. The dukes of York, Norfolk, Richmond, and Wellington, lords Shelburne, Talbot, Lauderdale, Townshend, Paget, Londonderry, Castlereagh, and Fox, Pitt, Sheridan, Canning, Hastings, Grattan, Curran, and O'Connell all fought duels. In the United States Charles Lee and John Laurens, Cadwallader and Conway, General McIntosh and Gwinnett, of the Revolutionary period, and Burr and Hamilton, Jackson and Dickinson, Benton and Lucas, Clay and Randolph, De Witt Clinton and Swartout, and Cilley and Graves, fought duels. In no part of the world was dueling so earnestly engaged in as in America. Combats under all sorts of conditions and with every conceivable variety of weapon, and in the great majority of instances fatal to one or both combatants, were of frequent occurrence, and largely because of this was precipitated the legislation which finally succeeded in stamping out the custom.

Laws now exist in all States of the Union against dueling. In some cases the punishment is death, in others imprisonment, and in others disqualification to hold office. A bill prohibiting dueling in the District of Columbia was passed in 1839.

At the beginning of the twentieth century the custom was almost universally prohibited by law, although countenanced, if not actually de-

manded, by officers, both naval and military, professional men and the upper circles generally, of continental European society. Organized efforts are now being made, however, to attack the custom in its own stronghold and among the classes who still cherish its traditions.

The International League, inaugurated in 1900 by Prince Alfonso of Bourbon and Austria-Este, has been organized with the declared intention of "setting right in the acceptance of society the sense of the words *cowardice* and *courage*, when used in connection with dueling." The French branch of the league is under the direction of M. Joseph du Bourg, and although its influence is as yet very limited, it has had the support of M. Paul de Cassagnac, formerly a well-known duelist, and was considerably aided by the refusal, in 1901, of Lieutenant Colonel the Marquis d'Elbée to accept the challenge of the Marquis de Chauvelin. Early in 1902 the league succeeded in forming a tribunal of honor in Paris, which consists of 14 members, six of whom are military or naval officers, and whose duties are to decide all disputed points without recourse to the duel. In the French provinces similar tribunals have also been organized and have already justified their existence. The anti-duelist movement in Germany is under the active direction of the Prince of Löwenstein and is very strong numerically and influentially. Its membership includes noblemen, soldiers, civilians, and university professors and students. The league publishes a representative periodical and is championed by nearly every prominent newspaper in the Empire. In Italy the Marquis Crispolti has been intrusted with the leadership of the movement, which however, was not begun until late in 1902. On Feb. 14, 1902, the Spanish Republican Fusion party, at Valencia, passed a resolution condemning the duel as contrary to civilization and forbidding members of the party from taking any part in a duel, either as principal or second. In Germany the Socialist party has taken a vigorous stand against dueling, and in 1912, upon the dismissal of a Catholic army officer who refused to maintain his honor by a duel, the Socialists and Catholics succeeded in carrying an antidueling resolution in the Reichstag.

In law, dueling is the criminal offense of engaging or participating in a combat with deadly weapons. The only form of the duel which was ever recognized by the common law was the judicial combat for the trial of appeals of battel, which was introduced into England by the Normans and formed a regular feature of the legal procedure under William the Conqueror and his immediate successors. The private duel, though much practiced during the mediæval period of English history, was never legalized, and was denounced and prohibited by a royal edict of James I in 1613 and by a decree of the Star Chamber in 1614. The hostility of the King's courts to the practice was pronounced, and it became an indictable offense. In the United States as well as in England to challenge or provoke a man to fight a duel is dealt with as an incitement to a breach of the peace, and to engage in such a combat is punished as an assault with deadly weapons. If a party to a duel is wounded, the other is indictable for unlawful wounding or for attempt to murder, and the killing of a combatant is punishable as homicide, the seconds and other participants being held equally guilty with the

principal. Consult: Villiger, *History of Dueling* (London, 1841); L. S. . . . Notes on Duels (Boston, 1855); G. Letainturier-Fradin, *Le duel à travers les âges* (Paris, 1892); Paulsen, *German Universities* (New York, 1906); E. Rouziet-Dorcières, *Sur le pré; souvenirs de duels, histoires contemporaines* (Paris, 1910). For a list of works on dueling, consult Levi and Gelli, *Bibliografia del duello* (Firenze, 1903). See ASSAULT; COMBAT; HOMICIDE; MURDER; and the authorities there cited.

DUE PROCESS OF LAW. A phrase used in the Federal Constitution and in the constitutions of many of the United States as the legal equivalent of "law of the land," in *Magna Charta* (q.v.). Some of our State constitutions contain both phrases, while others employ the words "due course of law" or "due course of the law of the land." All of these forms of expression are ancient and have long been understood to have the same meaning. They were used interchangeably in a series of statutes enacted under Edward III (5 Edw. III, c. 9; 25 id., c. 4; 28 id., c. 3) and were pronounced by Lord Coke to be legal equivalents. The Fifth Amendment of the United States Constitution declares that "No person shall be deprived of life, liberty, or property without due process of law," and the Fourteenth Amendment contains this clause: "Nor shall any State deprive any person of life, liberty, or property without due process of law." By this phrase is meant the regular and orderly determination of the rights of the citizen, whether by the ordinary courts of the land, the legislature, or by the people in enacting constitutional provisions. As applied to the courts it means law administered according to those rules and principles which have been established by our jurisprudence for the protection and enforcement of private rights; law which hears before it condemns, which proceeds upon due and orderly inquiry, and renders judgment only after trial.

This principle of constitutional law applies as well to the legislative and executive branches of government as to the judiciary. Neither Congress nor a State legislature can lawfully deprive a person of life, liberty, or property by arbitrary enactment. A statute attempting to do that would not be a law of the land, it would be unconstitutional and void. The same would be true of a like provision in a State constitution. To quote from a decision of the Supreme Court of Missouri: "It is as much out of the power of a State to deprive an owner of his property without due process of law through the medium of a constitutional convention as it would be thus to deprive him by an ordinary act of legislation." But for the check of this principle upon the legislature and the executive, bills of attainder, acts of confiscation, acts reversing judgments, and acts directly transferring one man's property to another might be resorted to, and the time-honored safeguards of constitutional liberty be swept away.

It is not to be understood, however, that the "law of the land" and "due process of law" mean the body of legal rules or the system of judicial procedure which existed at the adoption of the Federal or of a particular State constitution. These may be changed from time to time without violating the constitution, provided the new procedure or the new rules are in accordance with the fundamental principles and maxims of American jurisprudence. Moreover, a State may do

many things in the exercise of its police power which operate to deprive persons of liberty or property in a very summary way, without violating the constitutional provisions under consideration. But these acts are not performed without due process of law, since the State is acting in accordance with those principles governing the limiting the rights of the State and not at variance with them. "In short, 'due process of law' in each particular case means such an exercise of the powers of government as the settled maxims of law permit and sanction, and under such safeguards for the protection of individual rights as those maxims prescribe for the class of cases to which the one in question belongs." See **POLICE POWER**, and consult: Cooley, *Constitutional Limitations* (6th ed., Boston, 1890); Hare, *American Constitutional Law*, Lect. XXXV (Boston, 1889); Freund, *The Police Power* (Chicago, 1904); McGehee, *Due Process of Law under the Federal Constitution* (Chicago, 1906).

DUER, dū'ēr, JOHN (1782-1858). An American jurist, born in Albany, N. Y. From about 1820 until his death he practiced law in New York City. He was one of the commissioners to revise the laws of the State in 1823, was elected justice of the Superior Court in 1849, and in 1857 became Chief Justice. His most important work is *The Law and Practice of Marine Insurance* (2 vols., 1845-46).

DUER, WILLIAM ALEXANDER (1780-1858). An American jurist, born at Rhinebeck, N. Y. He practiced law at New Orleans, where he was the partner of Edward Livingston, and after 1812 in New York, where from 1814 to 1820 he was assemblyman and from 1822 to 1829 judge of the Supreme Court. In the latter year he was elected President of Columbia College, which position he held until 1842. He published: *Treatise on the Constitutional Jurisprudence of the United States* (1833); *Life of William Alexander, Earl of Stirling*, his grandfather (1847); *Reminiscences of an Old New Yorker* (1867).

DUERO, dwā'rō, or **DOURO**, dō'e-rō. A large river of Spain and Portugal, rising in the Spanish Province of Soria (Old Castile), 7389 feet above sea level, about 25 miles northwest of the city of Soria (Map: Portugal, A 2). It flows at first southeast and south, past Soria, receiving the waters of the Rituerto, and then pursues a general westerly course till it reaches the Portuguese frontier. It then flows southwest, forming for about 100 miles the boundary between Spain and Portugal, after which it flows almost due west across Portugal, emptying into the Atlantic 3 miles west of Oporto. Its total length is about 485 miles, over 160 miles of which is in Portugal. The Portuguese portion only is navigable, although its upper course might be utilized to some extent for transportation purposes, despite its swift, narrow current. The river is utilized for carrying the yield of the rich wine-producing territory of the interior to Oporto. Its mouth is closed by a bar and a number of sand banks, which can be passed by ocean-going vessels only, during high tide. The tributaries of the Duero are generally short, the greater number belonging to the Spanish portion. The most important are the Pisuegra, Valderazduy, Esla, Tua, and Tamega, on the right, and the Adaja, Tormes, and Agueda, on the left.

DUERO, MARQUÉS DEL. See CONCHA, MANUEL GUTIERREZ DE LA.

DUET' (It. *duetto*, from Lat. *duo*, two). A composition for two voices or instruments, with or without an accompaniment of one or more instruments. In technical language, *duet* is applied to a composition for two voices or instruments of the same kind, while *duo* refers to one for two voices or instruments of different kinds.

DUEZ, dū'ā', ERNEST ANGE (1843-96). A French genre, portrait, and landscape painter. He was born in Paris and studied there under Pils. After he had obtained several medals at the Salon, his large religious painting, "St. Cuthbert" (1870), was acquired by the Luxembourg. He later painted some fine portraits of those of Madame Duez and Ulysse; (Luxembourg Museum), but devoted himself chiefly to landscapes and to genre scenes of Parisian life. These are brilliant in color, and fine in line, although in some cases he carried realism to an extreme. He obtained a first-class medal in 1879 and the cross of the Legion of Honor in 1889.

DUFAU, dū'fō', PIERRE ARMAND (1795-1877). A French economist and publicist, born at Bordeaux. At the age of 20 he was appointed instructor at the Institute for the Blind, Paris. In 1840 he became director of the institution, and during the following 15 years of his official activity published a great number of works on the treatment and education of the blind. He was also one of the principal founders of the Aid Society for the Blind, established at Paris in 1851. His more important publications include: *Plan de l'organisation de l'institution des jeunes aveugles* (1833); *Statistique comparée des aveugles* (1854); *De la réforme du mont-de-piété* (1855).

DUFAURE, dū'fōr', JULES ARMAND STANISLAS (1798-1881). A French statesman, born in Saujon, Charente-Inférieure. He studied law in Paris, was chosen deputy from Saintes in 1834, and acquired great influence in the Liberal party, of which he had been chosen a life member in 1876. In 1863 he was elected to the Academy, taking Pasquier's place. He was appointed Councilor of State in 1836 and Minister of Public Works in 1839. In 1844 he was chosen Vice President of the Chamber and after the revolution of 1848 was Minister of the Interior. Louis Napoleon gave him the same office, but after the coup d'état he returned to the practice of law. In the formation of the Third Republic he took an active part. He was made Minister of Justice in 1871, 1875, and 1877; but when Grévy became President, in 1879, Dufaure resigned permanently from the ministry, though he continued in the Senate. Consult G. Picot, *M. Dufaure, sa vie et ses discours* (Paris, 1883).

DUFAY, dū'fā', GUILLAUME (c.1400-74). The greatest master of the first Flemish school of composition. He was born probably at Chimay in Hainaut. From 1428 to 1837 he was a singer in the Papal Chapel, from 1442 to 1449 he lived in Paris, and he died in Cambrai. Many reforms regarding musical notation are attributed to him. At any rate, he cultivated four-part writing with such success that since then it has always been regarded as the foundation of all choral writing. Numerous compositions are preserved in various libraries, and selections from his masses, motets, and chansons, have been published by Haberl and Stainer. Consult F. Haberl, "Wilhelm Du Fay," in *Bausteine für Musikgeschichte* (Leipzig, 1885),

and J. Stainer, *Dufay and his Contemporaries* (London, 1898).

DUFF, ALEXANDER (1806-78). A Scottish missionary to India, born at Auchmayle, Perthshire. He was educated at the University of St. Andrews, was ordained to the ministry of the Church of Scotland in 1829, and in the same year was sent as the first missionary of that church to India. He established his headquarters at Calcutta and decided to conduct his work on a new basis, by founding a school which should later expand into a college and in which the English language should be used for instruction, first in the Bible, and secondly in Western knowledge generally, and so to make an appeal to the upper classes. His plan was to carry on evangelistic activity largely by means of educated native preachers. Upon the disruption of the Church of Scotland, in 1843, he adhered, with all other foreign missionaries of the denomination, to the Free church. He was therefore obliged to surrender the mission, with its entire equipment, to the Establishment, to which it legally belonged. Soon, however, he developed a new institution larger and more efficient than the old, with branch schools in surrounding villages. In 1849 he was compelled by ill health again to visit Scotland, where he remained until 1856. In 1851 he was called to the chair of the General Assembly of the Free church and in 1854 traveled and spoke in the United States. He assisted in founding the University of Calcutta and in 1864 permanently returned to Scotland. He was appointed the first professor of comparative theology at New College, Edinburgh, in 1867, and in 1873 was again elevated to the chair of the General Assembly. It was chiefly through his agency that the Livingstonia Free Church Mission, on Lake Nyassa, Africa, was organized. His publications include *The Church of Scotland's India Mission* (1835), and *The World-Wide Crisis* (1873). Consult Smith, *The Life of Alexander Duff, D.D., LL.D.* (London, 1879).

DUFF, ARCHIBALD (1845-). An English Old Testament scholar, born in Fraserburgh, Aberdeen. He was educated at McGill University, Montreal, at Andover Theological Seminary, at Halle, and at Göttingen. Before studying theology he was (1864-69) a high-school teacher in Canada. In 1878 he became professor of Hebrew and Old Testament Theology in the (Congregational) United College at Bradford. In 1874-94 he was an editor of the *Bibliotheca Sacra*. His more important works were: *Old Testament* (1891; 1900); *Hebrew Grammar* (1901); *Theology and Ethics of the Hebrews* (1902); "First and Second Esdras" (1903), in *Temple Apocrypha*; *Abraham and the Patriarchal Age* (1903); *Modern Old Testament Theology* (1908); *History of Old Testament Criticism* (1910); and, translated from the German of Duhm, the *Book of the Twelve Prophets* (1912).

DUFF, MARY ANN (1794-1857). A tragic actress, in her time the greatest upon the American stage. Her maiden name was Mary Ann Dyke, and she was born in London. She made her début in Dublin in 1808, and there she became the wife of an Irish actor named John Duff, with whom she came to America in 1810. She first appeared in Boston as Juliet and made her reputation in this and other tragic rôles, including Ophelia, Desdemona, and Lady Macbeth. In 1821, in Boston, she played Hermione

in *The Distress Mother* so powerfully that Edmund Kean feared it might be forgotten that he was the "star." She first appeared in New York in 1823, as Hermione, to the Orestes of the elder Booth. In 1828 she played at Drury Lane, London, but soon returned to America. In 1835 she played for the last time in New York and was married to Mr. Seaver, of New Orleans. There occurred her farewell to the stage in 1838. Consult Ireland, *Mrs. Duff* (Boston, 1882).

DUFF, MOUNTSTUART ELPHINSTONE GRANT (1829-1906). An English diplomat and man of letters, born at He studied at Edinburgh and Balliol College, Oxford, was called to the bar in 1854, and from 1857 to 1881 sat in Parliament for the Elgin Burghs, rising to be Undersecretary of State for India (1868-74) and for the Colonies (1880-81). From 1881 to 1886 he was Governor of Madras, and on his return to England acted as president of the Royal Geographical Society (1889-93) and the Royal Historical Society (1892-99). His writings include a number of studies in foreign politics, memoirs of Henry Sumner Maine (1892) and of Renan (1893), *Miscellanies, Political and Literary* (1878), and *Notes from a Diary* (1897-1905), covering the years 1851-1901. Consult the essay on the "Diaries" in Wilfrid Ward's *Ten Personal Studies* (London, 1908).

DUFFERIN AND AVA, á'vâ, FREDERICK TEMPLE HAMILTON BLACKWOOD, MARQUIS OF (1826-1902). A British diplomat and statesman. The only son of the fourth Lord Dufferin, he was born in Florence, Italy. He was educated at Eton and Oxford. He became fifth Baron Dufferin, of Clandeboyne, Ireland, at the death of his father, in 1841, and was lord in waiting to the Queen for several years, under two administrations. He distinguished himself by literary production and in 1855 was attached to the Austrian mission. In 1860 he was sent as British commissioner to Syria to inquire into the massacre of Christians. In 1864 he was appointed Undersecretary of State for India; in 1866, Undersecretary for War; and Gladstone in 1868 made him Chancellor of the Duchy of Lancaster. From 1872 to 1878 he was Governor-General of the Dominion of Canada. He was Ambassador to Russia from 1879 to 1881. While Ambassador to Turkey (1881-84), he went to Egypt to restore order after Arabi Pasha's rebellion. His viceroyalty of India (1884-88) was marked by the annexation of Burma, and an amicable delimitation of the Afghan frontier with Russia, after the Penjdeh affair. He was Ambassador to Italy from 1888 to 1891 and Ambassador to France from 1891 to 1896, when he retired from the diplomatic service. From 1891 to 1895 he was Lord Warden of the Cinque Ports. He received a number of titles, including an earldom in 1871 and the marquise of Dufferin and Ava in 1888. The degree of LL.D. was conferred upon him by several universities and colleges. Oxford University gave him the degree of D.C.L., and Punjab University, a doctorate of Oriental learning. In 1878 he was elected president of the Royal Geographical Society and in 1891 lord rector of Glasgow University. Among his published writings are: *Narrative of a Journey from Oxford to Skibbereen during the Year of the Irish Famine* (1846-47); *Letters from High Latitudes*, descriptive of a yacht voyage to Iceland (1859); *Contributions to an Inquiry into the State of Ireland* (1866); *Irish Emigration and the Tenure of Land in Ireland*

(1867); *Speeches and Addresses* (1882). His wife, Harriet Hamilton, is well known for her philanthropic work among the native women of India and for the interesting books: *The Record of Three Years' Work* (1889); *Our Vice-Regal Life in India* (1890); *My Canadian Journal* (1891). Consult Lyall, *Life of the Marquis of Duff and Ava* (London, 1905).

DUFF-GORDON, LADY LUCIE. See GORDON.

DUFFIELD, GEORGE (1794-1868). A Presbyterian clergyman, born at Strasburg, Pa., a grandson of the Rev. George Duffield (1732-90), who was for a time chaplain to Congress. He studied at the University of Pennsylvania in 1811 and was ordained in 1815. He had charges successively in Carlisle, Pa. (1815-34), Philadelphia, New York City, and Detroit (1838-68), and from 1840 to 1848 was regent of the University of Michigan. He was distinguished by a progressive spirit and was prominently identified with the "new-school" movement. In 1832 he was tried for heresy, but was acquitted. In 1862 he was moderator of the New School General Assembly. His publications include: *Regeneration* (1832); *Claims of Episcopal Bishops Examined* (1842); *Travels in the Holy Land; The Divine Organic Law, . . . or Capital Punishment for Murder Authorized by God* (1848).

DUFFIELD, GEORGE (1818-88). An American Presbyterian clergyman, son of the preceding, born at Carlisle, Pa. He graduated at Yale in 1837 and at Union Theological Seminary in 1840. He held pastorates in Brooklyn, N. Y. (1840-47), Bloomfield, N. J., Philadelphia, Pa. (1852-61), Adrian, Mich. (1861-65), Saginaw, Mich. (1869-77), and Lansing, Mich. (1877-80). He wrote many hymns, of which "Blessed Saviour, Thee I Love" (1851) and "Stand up, Stand up for Jesus" (1858) are the best known.

DUFFIELD, JOHN THOMAS (1823-1901). An American clergyman and mathematician, born at McConnellsburg, Pa. He graduated at Princeton in 1841 and at the Theological Seminary in 1844 and in 1851 was ordained to the ministry of the Presbyterian church. From 1847 to 1850 he was adjunct professor of mathematics at Princeton, in 1850 was appointed professor of mathematics, and from 1862 to 1871 was also professor of mechanics. He wrote *The Princeton Pulpit* (1850) and various monographs, including *The Philosophy of Mathematics* (1866).

DUFFIELD, SAMUEL WILLOUGHBY (1843-87). An American Presbyterian clergyman and hymnologist, son of George Duffield (1818-88). He was born in Brooklyn, N. Y., and was educated at Yale, where he graduated in 1863. After 1882 he preached in Bloomfield, N. J. His publications include: *Warp and Woof*, a book of verse (1870); *English Hymns: Their Authors and History* (1886); *Latin Hymn-Writers and their Hymns* (1889), a posthumous publication, completed by Robert Ellis Thompson.

DUFFIELD, WILLIAM WARD (1823-1907). An American soldier, born at Carlisle, Pa. He graduated in 1841 at Columbia, served in the Mexican War, and was engineer in the construction of several railways. In 1861 he was appointed lieutenant colonel of the Fourth Michigan Infantry, during the Civil War was twice wounded at Murfreesboro, and rose to be brigadier general and brevet major general. From 1878 to 1879 he was a member of the Michigan Senate, later was active as a railway engineer, in 1892-93 was United States engineer on the White and Wabash rivers, and in 1894-

98 was superintendent of the United States Coast and Geodetic Survey. In the *Survey Report* for 1895-96 he published a valuable table of 10-figure logarithms to 100,000, newly calculated.

DUFFY, SIR CHARLES GAVAN (1816-1903). An Irish patriot and author, born in the County of Monaghan, Ireland. In 1842 he founded, in company with Thomas Davis and John Dillon, the *Dublin Nation*, as the organ of the Young Ireland party. In 1846 O'Connell quarreled with the Young Ireland party, which thereupon reorganized under the name of the Irish Confederation. With other members of that body Duffy was tried for treason felony (1848), but was acquitted. He then revived the *Nation*, founded the Irish Tenant League, was elected to the House of Commons (1852), and established the Independent Irish party, but, on account of the opposition of the ultra-Roman Catholics, resigned in 1856 and emigrated to Australia, where he took up the practice of law. He became Minister of Public Works in Victoria (1857), entered the Parliament there, and was Prime Minister in 1871. He was knighted in 1873. Returning to Europe in 1880, he took up his residence at Nice. He published *Ballad Poetry of Ireland* (1845), which has passed through 50 editions; *Young Ireland* (1880), and its sequel, *Four Years of Irish History* (1883), which together cover the period from 1840 to 1850; *Conversations with Carlyle* (1892); *Memoirs* (1898); and other works. Its distillation of the essence of Irish history into a brief, rapid, and interesting narrative makes his *Bird's-Eye View of Irish History* (1882) an extraordinary tour de force.
